complete gangrene of the superficial portions was seen, in which there were many Vincent's spirochetes and myriads of other bacteria. Below this were a marked growth of reticular cells in the soft tissues and penetration of spirochetes alone deep into the non-necrotic base of the ulcer.

Smears of the spleen and lymph nodes showed the predominating cells to resemble those in blood smears and only the few granulocytes present were peroxidase positive. A few more granulocytes chiefly myeloblasts were found in smears of the bone marrow. No bacteria were demonstrated in smears or sections of any of the organs.

CASE 2—Mrs M R, a white woman, aged 22, entered the Los Angeles County General Hospital on Jan 18, 1932, complaining of pain in the throat and a swelling in the left tonsillar area of one week's duration, which had ruptured and discharged pus two days before admission, general malaise and loss of appetite. Examination showed a draining peritonsillar abscess, and the rest of the examination was essentially negative, except that the patient appeared pale and sicker than she should from the local lesion in her throat. A blood count revealed anemia and leukopenia which could not be explained

Fig 4 (case 1)—Liver showing periportal reticular hyperplasia. Low power view

After transfusion on January 31, she felt considerably better, but her temperature did not return to normal for three weeks from its average of 101 F in the first week. She left the hospital against advice on February 18 and was not heard of again until March 30, when she returned to the hospital still complaining of pain in the left tonsillar area, fever, generalized aching malaise and swelling of the nodes in the neck which had started to develop shortly after she left the hospital. On examination, she appeared acutely ill and pale with a temperature of 101.6 F. There were swelling and redness of the mucosa of the throat, pharynx and palate and a gray membrane was present over the previously incised region in the left tonsil. Moderate enlargement of the cervical and submaxillary nodes but not of the nodes of the groins and axillae was present. The spleen and liver were not felt. The heart and lungs were normal. No petechiae were found in the skin.

Laboratory examinations revealed negative Wassermann and Kahn tests, several negative blood cultures and negative urinalysis except for a trace of albumin. A Widal test was positive at a dilution of 1:80 but the patient had had typhoid in late childhood. The blood counts are given in table 2.

TABLE 2—Blood Findings in Case 2

Date	Hemo- globin (Sahli)	Red Cells Millions	Wuko ocytes	Neutro- phils	Lym- pho- cytes	Mono- cytes	Pol- yphils	Baso- phils
1-20-32		2.6	1,000		71	1	0	0
1-31-32		2.7	1,200		70	1	0	0
2-1-32		2.6	2,000		59	1	0	0
2-11-32	64	2.4	2,000		70		0	0
2-11-32	67	2.4	4,000	40		3	1	1
3-1-32	60	2.5	14,000				0	0
4		2.4	4,000	1	5	4	0	0

The monocytes in smears up to and including those made on February 11 were mature monocytes but in the last two smears made on March 31 and April 5 they were practically like those in case 1.

The cells described as monocytes were similar to those in case 1. They were almost entirely immature cells with a fine chromatin pattern in their nuclei and occasionally one or more small nucleoli. The cytoplasm was a typical dull blue with

very fine, dustlike, blue granules throughout the entire cytoplasm in most cells, and about the nucleus in the youngest cells. A few cells had no granules. Pseudopod formation and scalloping of the edges of the cells were prominent. The peroxidase stain failed to show granules in the monocytes.

The patient went steadily downhill, the ulceration and swelling in her throat increased and her temperature remained around 102 or 103 F, she died on April 6. The clinical diagnosis was acute monocytic leukemia. Autopsy was conducted two hours after death by Dr Butt. The summary is as follows:

The anatomic diagnosis was acute leukemic reticulo-endotheliosis with moderate generalized involvement of the lymph nodes, moderate enlargement of the spleen and liver and moderate reticular hyperplasia of the bone marrow, reticular cell proliferation in the pancreas, ovaries, kidneys, lungs, suprarenal glands, uterus, heart, pleura, pericardium and thymus, acute hemorrhagic bronchopneumonia, ulcerogangrenous inflammation of the left tonsillar region, acute fibrinous pleurisy, anemia, petechial hemorrhages in the skin of the shoulders, arms and thighs and the pleurae.

The lymph nodes were moderately enlarged, the largest, in the mesenteric group, being 1.5 cm long. The nodes were discrete, soft and gray-white on section. The spleen weighed 550 Gm; the pulp was rather firm, red and homogeneous. The liver weighed 2,100 Gm; the sectioned surface was pale, and the peripheries of the lobules were visible as small gray points. The bone marrow of the femur was composed of fat, enclosing small gray areas, and that of the sternum was nearly fat-free and gray-red. Both lungs were covered on their dependent surfaces with a thin layer of fibrin. A few petechial spots were also found. The dependent portions were boggy and edematous and showed a few small consolidated areas with much hemorrhage. The heart was moderately dilated. The epicardium showed a few petechiae. The ovaries were moderately swollen and on section appeared soft and gray-red.

Histologic study revealed findings practically similar to those in case 1. Proliferation of similar reticular cells without endothelial hyperplasia was seen in all the organs, including the uterus and ovaries most marked in the spleen and lymph nodes where the normal architecture was obliterated by a profound growth of these cells. The growth in the liver was

Fig 5 (case 1)—Thymus showing marked growth of reticular cells similar to leukemic cells in blood capillaries. High power view

periportal. Some toxic were found in the myocardium in and about which necrosis of the muscle fibers was present.

CASE 3—Mrs L B, a housewife aged 58 entered the Los Angeles County General Hospital on Jan 18, 1933 complaining of weakness, loss of appetite and burning on urination of about six weeks duration previous to which she had been well and active. At the onset of her illness she had several teeth removed and two days later she had fever and general malaise which she called the flu. However she had no cough or respiratory symptoms. Soon thereafter burning

and frequency of urination developed which continued until admission. She constantly felt so tired and weak that she could not do her housework. Her appetite had been so poor that she had lost a moderate amount of weight. Some stuffiness of the nose and soreness of the throat had developed in the last few weeks. Her past history and family history were irrelevant, except that she had never had urinary burning or frequency until the present illness. She had no history of cough or shortness of breath until the last few weeks when these symptoms developed to a moderate degree.

On examination she appeared to be poorly nourished, anemic and considerably older than her given age. The positive findings of interest were pallor of the skin and mucosae and absence of all teeth, the sites of the recent extractions were not entirely healed. The tongue was coated, the pharynx clear and the tonsils large, smooth and reddened. There were a few small pea-sized movable lymph nodes in the groins but none in the other palpable groups. The heart was rapid but otherwise showed nothing of interest. The lungs were resonant throughout, the breath sounds were normal. The spleen was not palpable, but the liver extended one fingerbreadth below the margin of the ribs. Pelvic examination gave negative results. The temperature was 99° F, the pulse rate 100, the respiratory rate 22 and the blood pressure, 130 systolic and 70 diastolic.

On admission, urinalysis showed a cloudy acid urine; the specific gravity was 1.028; there was 2+ albumin; the urine was negative for sugar and in the sediment there were numerous leukocytes but no crystals. The Wassermann and Kahn tests were negative.

A blood count taken on Jan 22, 1933, showed hemoglobin 44 per cent (Sahli), red cells 2,330,000, white cells 35,400 and platelets 207,000. There was no excess bleeding from the puncture wound. Study of the smear showed myeloblasts 12 per cent, neutrophils 45 per cent, lymphocytes 7 per cent, monocytes, 72 per cent and promyelocytes 45 per cent. The monocytes or type cells were large cells from 20 to 40 microns in diameter with abundant pale blue cytoplasm containing fine purple granules much finer than those in leukoblasts situated chiefly about the nucleus or throughout the entire cytoplasm. The nuclei were of various degrees of immaturity, most of them showing a very fine arrangement of chromatin. Most of the nuclei were ovoid, indented, kidney shaped or even partially or completely lobed. Many of the cells showed pseudopodia and nearly all showed scalloped or fluted borders. Transitions from these cells to myelocytes could not be demonstrated. On January 26, the white count was 42,000 and on February 2, 76,000. Smears showed practically the same differential count as previously. On February 10, the white cell count was 60,000 and the differential count was as follows: myeloblasts 9 per cent, leukoblasts, 13 per cent, promyelocytes, 25 per cent, metamyelocytes, 1 per cent, neutrophils, stab forms 1 per cent and segmented forms 35 per cent, lymphocytes, 6 per cent and monocytes, 64 per cent. The cell picture was the same as that just described.

The patient went progressively downhill, running a fever of from 99 to 100° F during the entire stay in the hospital. Her spleen was never palpable, but moderate generalized lymphadenopathy developed, the largest nodes about 2 cm long, being felt in the groin. A blood transfusion of 500 cc was given on February 10 but within a few days the patient appeared as pale as before. During the last two weeks more marked redness and swelling of the tonsils and peritonsillar regions, palate and laryngeal aperture developed, with marked embarrassment to respiration and swallowing. No ulceration, however, was noted. There was no abnormal bleeding during the illness. Death occurred on February 23, or about eleven weeks from the onset of the disease. Permission for autopsy was refused but a small, soft, gray pea-sized node was removed from the groin three weeks before death. On section it showed obliteration of the normal architecture by a marked proliferation of the reticular cells of the same type as in cases 1 and 2. Rarely an eosinophilic myelocyte was also seen. Smears made from the node showed a predominance of large mononuclear cells similar to those in the blood.

CASE 4—Mrs L. A., aged 52, was admitted to St. Francis Hospital, San Francisco, on March 10, 1933, with the history

of having had a tooth extracted from the left side of her upper jaw on February 10. The socket apparently healed well, but one week later she had swelling of the lymph nodes about the angle of the left side of the jaw. Considerable pain and swelling developed in the whole left side of the upper jaw about the same time, and she was compelled to spend most of her time in bed. Moderate fever was present at this time. The inflammation failed to respond to cold compresses and gargles; the pain became more severe, the gums became swollen and tender and bled easily but not spontaneously and the patient was sent to the hospital. She became progressively worse and had a fever of from 101.6 to 104.6° F. The pulse rate varied from 90 to 140 and the respiratory rate, from 28 to 44. She died on March 14. Her spleen, liver and axillary and inguinal lymph nodes were not palpable. Dr. A. M. Moody, pathologist, who allowed me to study the smears and report the case, first made the diagnosis of monocytic leukemia on the clinical history and the blood findings, which were as follows: On March 10, the hemoglobin was 5.5 Gm, the red cells numbered 2,470,000 and the white cells 105,000. The differential count showed myeloblasts 1 per cent, leukoblasts 1 per cent, metamyelocytes 0.5 per cent, neutrophils stab forms, 1 per cent and segmented forms 25 per cent, lymphocytes 6 per cent and monocytes 88 per cent. The next day there were 92,700 white cells with 85 per cent monocytes. On March 12, the hemoglobin was 5.2 Gm, the red cells numbered 2,070,000 and the white cells 102,000 of which 87 per cent were monocytes. On March 13, the blood count showed 116,800 white cells with 86 per cent monocytes.

The cells classed as monocytes were with rare exceptions immature monocytes with nuclear shape and characters similar to those in cases 1 and 2. Pseudopod formation was often seen and fine granulation of the cytoplasm was found in nearly all of the cells. The cells were peroxidase negative.

A blood culture was negative. The reaction to the Wassermann test was 4+; that to the Kahn test, 2+. Autopsy was not allowed.

COMMENT

The first two cases were typical examples of acute reticulo-endotheliosis. The first was leukemic from the start, and the second was aleukemic until the patient's second admission to the hospital when the white cell count was found to be high. The fourth case showed a typical blood picture and it is regretted that an autopsy was not allowed in order to determine the changes in the tissues. Case 3 is open to some question since not sufficient counts were made and autopsy was not granted. The presence of a moderate percentage of immature myelogenous cells (17 per cent) is suggestive of a myeloblastic origin of the monocytes, but the biopsied node showed predominantly reticular cell proliferation, and the monocytic granules in the blood smear were peroxidase-negative, two points which lead us to believe that this case also should be grouped with the others as acute leukemic reticulo-endotheliosis or monocytic leukemia.

SUMMARY

Leukemic reticulo-endotheliosis (monocytic leukemia) is a distinct condition characterized by the presence of a clinical picture similar to that in other acute leukemic states and the presence of an extraordinary number of monocytes in the blood usually immature forms. Pathologically, a diffuse enlargement of the lymph nodes, spleen and liver is found, and in the microscopic examination of the tissues, widespread proliferation of reticulo-endothelial cells is found to a degree as great as or greater than is usually found in the so called infiltrates of other leukemias.

A report of four cases conforming to the foregoing feature with autopsies in two and biopsy in one is given.

ABSTRACT OF DISCUSSION

DR ROY R KRACKE, Emory University, Ga During the past year the Hematological Registry of the American Society of Clinical Pathologists has centered its activities chiefly on the study of monocytic leukemia. In the Scientific Exhibit there are twenty-six blood films and autopsy preparations from cases that have been reported in this country and from all of the cases that have been reported from Great Britain. There is justification for establishing this disease as a clinical entity only if the view is accepted that the monocytes have a separate origin from other leukocytes. Of the twenty-six cases, one third were reported as monocytic leukemia, in spite of the fact that the leukocyte count seldom if ever went above the normal figure, the diagnosis being established chiefly on the immaturity of the cell type that was found in predominating numbers. This so-called aleukemic state is seen in monocytic as well as in other leukemias. I have been impressed by the close relationship that seems to exist between the aleukemic states of monocytic and other leukemias with agranulocytosis. For example there is one case reported in the literature in which at one time the white cell count was 600, with complete disappearance of cells except lymphocytes. Therefore the diagnosis of agranulocytosis was made. Yet in this patient only a few weeks later the white cell count was over 100,000. Four of the cases seem to be of undoubted myeloid origin presumably originating in the marrow. There is one case reported by Lawrence three years ago a typical case of monocytic leukemia in which the diagnosis was made on clinical observations, fixed films and supravital studies, which later eventuated into a definite case of myeloid leukemia. This is in accordance with the views of many hematologists especially the Europeans and notably the school headed by Naegeli, who believe that monocytic leukemia should not be construed as a clinical entity in which the cell type is the monocyte or monoblast, but that these are temporary variants of myelogenous leukemia. As Naegeli states, they will finally pass into myeloid leukemia if the patient lives long enough. I am inclined to believe that there are two types of monocytic leukemia, one in which there is a true reticulo endotheliosis as exemplified by the four cases that have been presented by Dr Foord and another which apparently has its origin in the bone marrow and which should more properly be called an acute or atypical myeloblastic leukemia. It may be possible that in these blood dyscrasias, on the one hand, an excessive stimulation of the bone marrow occurs, whereas on the other hand the depression of the same functions results in agranulocytosis. There are many factors in common between the two diseases. Apparently both are of recent origin being reported only within the past fifteen years and occurring only in white persons. I agree with Dr Foord in his interpretation of his cases in that they seem to be cases of true reticulo endotheliosis and probably not variants of myeloid leukemia.

DR C H BUNTING, Madison Wis I have seen four cases that might come under this classification. I have however, objected to the name monocytic leukemia on theoretical grounds. If as appears probable the normally circulating monocyte is of bone marrow origin and among its other characteristics gives the oxidase reaction the majority of these reported cases could not be considered to be typically monoblastic leukemias. Two of the cases I have seen were shown pathologically to be primarily of lymph node origin. They showed in addition to very pathologic large cells somewhat resembling monocytes a fairly high percentage of much larger cells with large oval nuclei and prominent nucleoli typical morphologically of endothelial cells. The third case clinically of lymph gland origin presented no endothelial cells but a preponderance of atypical monocyctoid cells the size of large lymphocytes and also atypical small lymphocytes. The fourth case seen in the last two weeks and without completed pathologic examination might be called monocytic leukemia as the preponderant atypical cells gave a sharp peroxidase reaction. It must be granted however that in any type of leukemia one cannot disregard any part of the leukopoietic system, bone marrow, lymphoid tissue and spleen are all involved in any reaction within the system.

DR R S PORTER, Philadelphia I want to mention a case of Dr Crocker and I observed in the Philadelphia General

Hospital, of aleukemic monocytic leukemia diagnosed during the life of the patient which I believe is unique in the report of these cases. The diagnosis was based on a biopsy of the sternal marrow and a biopsy of the lymph glands and was confirmed by autopsy. It is interesting in our case that there was present a very marked reticulo-endothelial hyperplasia. The case was similar to those reported by Dr Kracke in that infection, i e, otitis media preceded the onset of the illness, which was in an Italian girl, aged 14 years. Several times during the course of her illness the peripheral blood study showed a complete absence of the granulocytic series of cells, and a diagnosis of agranulocytosis therefore was considered. The biopsy and autopsy indicate that it is unsafe to base a diagnosis on the study of the peripheral blood alone, in these cases. The question of Vincent's infection came up in this case. While the girl had an acute otitis media no Vincent's organisms could be found except toward the end of her illness when they were found in the vagina. At necropsy no lesion in the vagina could be noted. The question of Vincent's infection as an etiologic factor in these conditions is always interesting. Dr Crocker, hematologist at the Philadelphia Hospital, believes that Vincent's organisms are an etiologic factor, in spite of certain studies showing a lack of pathogenicity. Whether the Vincent organisms can be subdivided into various strains and certain strains be etiologic in nature is worth considering. Crocker has found that those occurring in ordinary trench mouth gingivitis are of a coarse, heavy structure, whereas those associated with agranulocytosis are of a much finer, threadlike structure.

DR FREDERIC E SONDERMAN, New York Clinically it might be well to emphasize the significance of the red cell picture in cases of monocytic leukemia. In my experience with quite a number of them the immediate prognosis is better based on the type of anemia and the rapidity with which it increases than on the number and types of leukocytes as long as these establish the diagnosis. In other words, a picture typical of pernicious anemia with only moderate leukocytosis and moderate characteristic change in the differential count offers a poorer immediate prognosis than a picture typical of secondary anemia with a more marked leukocytosis and more pronounced characteristic change in the differential count. Occasionally there is a recovery from this disease, while such a course may represent an error in diagnosis, this seems difficult to believe on account of the typical blood picture. I recall three such supposed recoveries. In one the acute febrile stage with increasing anemia lasted some ten weeks, but it was five years before the leukocytes and the relative increase in monocytes returned to normal figures. In the two others the acute stage was not as severe and typical blood pictures were months in returning to normal. It is an interesting fact that the organisms of Vincent's angina were found in the throat of every patient I have seen with but one exception. Years ago I had the impression of a probable relationship between these organisms and acute leukemia but since then I have also repeatedly found them in cases of infectious mononucleosis.

DR VICTOR LEVINE, Chicago There have recently been three cases of leukemia at the Cook County Hospital two of which were true monocytic leukemias and one a case we could not diagnose until postmortem but it proved to be a monocytic phase of a myelogenous leukemia. In all three cases a postmortem examination was performed and the final basis for our diagnosis was the histologic examination of the bone marrow. In the case with the uncertain diagnosis before death the blood contained monoblasts and myeloblasts the monoblasts being in marked predominance. Yet at postmortem the bone marrow was essentially that of a myelogenous leukemia with a preponderance of myeloblasts and myelocytes. On the other hand the two cases of true monocytic leukemia showed at postmortem a marked predominance of monoblasts and monocytes. Thus in cases of monocytic leukemia the bone marrow may be involved to an extent similar to that found in any other type of leukemia. In making a diagnosis of monocytic leukemia the essential blood finding is the presence not only of large numbers of monocytes but also of numerous examples of the immature precursors of the monocytes which we call monoblasts. Case reported without the presence of these immature

forms are not true monocytic leukemias. Cases of this type, especially those in children, often following throat infections, should be classed as acute infectious mononucleosis. Unfortunately the literature is full of conflicting terms. The term "reticulo-endotheliosis" does not seem good, because it more properly belongs to cases of infectious origin with marked proliferation of reticulum and histiocyte cells in various organs. Such cases are not true leukemias. They do not have the typical blood and anatomic pictures and should be sharply separated from monocytic leukemia.

DR. A. G. FOORD, Pasadena, Calif., In answer to Dr. Levine, I do not care to enter into a discussion of terminology but have merely followed the terms used by others in the literature and have included both the terms of leukemic reticulo-endotheliosis and monocytic leukemia in the title and have stressed the former name because the discussion was primarily from the pathologic standpoint. Since there is still a dispute as to the origin of the monocytes, I purposely refrain from entering into this phase of the subject. However, from present knowledge it appears that Dr. Kracke is right as to the origin of these cells from the reticulum cells in some cases and from the myeloblasts in others. In answer to Dr. Sondern, I can say that there are no cases reported in the literature in which the patients have recovered. In some cases of acute mononucleosis the cells in the blood are very hard to differentiate from the cells in the cases reported but all cases with cells as those described end fatally. The immaturity of the nuclei is a very important feature in making the diagnosis.

RELAPSED OR RESISTANT CLUBFOOT OF EARLY CHILDHOOD

BURT G. CHOLLETT, M.D.
TOLEDO, OHIO

There are three distinct types of deformity to which the title of congenital talipes equinovarus can be given: 1. The common variety, which, except in rare instances, occurs in otherwise normal infants. 2. A rare type associated with, and part of, a failure of development of the extremity as a whole, either of the lower limbs alone or of the upper limbs as well, also arthrogryposis. 3. A rare type associated with the absence of the tibia and some of the toes.

If a real criterion is set for cured clubfoot, every clinic will have a certain number of disappointing results after all types of closed procedures have been exhausted. This is true even when treatment has been instituted early and efficiently carried out.

Pathologic specimens of clubfoot in infancy are rare. Most of the descriptions in the literature on this subject and specimens in museums are of the adult foot. Recognition of the size and location of the bones is difficult because the amount of subcutaneous fat present in the foot of the infant and small child hides the bony prominences, and the direction of the tendons is obscured and not easily located or traced to their insertion. Roentgenograms are an aid in older children but less helpful in early childhood before the bones are well developed, as there is no roentgenologic visibility.

At present, the widely accepted cause in common clubfoot is a failure of development to the normal state of all the structures of the foot, independent of any extrinsic influences, which results in a congenital subluxation of the astragalocalcaneoscaphoid joint and a shortening of the muscles and ligaments that control the socket for the head of the astragalus. The bones of the forefoot are relatively underdeveloped, and

movements of the foot are restricted by the muscle shortening.

The bones of the foot, except in rare instances, though underdeveloped, are otherwise normal and are held fixed in the equinovarus position by the shortened ligaments, which have failed to develop, and by the underdevelopment of the muscles of the leg and foot, which is also a part of the primary failure of development of the entire limb.

When the normal foot is placed in equinovarus, the chief movement takes place in the astragalocalcaneoscaphoid joint, the other joints of the foot add little to the ability to assume this position. On comparing the normal foot held in equinovarus with clubfoot, it is found that the latter shows an exaggeration of this position. The astragalus is subluxated and separated from the scaphoid, which is internal and below the head of the astragalus, the os calcis is more inverted, and the muscles and ligaments are shortened, thus fixing the foot in equinovarus.

A survey of the last eighty cases of clubfoot in my clinic showed that a large number, approximately 45

Fig. 1.—Taken from a specimen of congenital clubfoot in the Museum of the Royal College of Surgeons, London. This specimen illustrates very clearly the position which the astragalus occupies within the tibio-fibular mortise. It also shows the difficulty that must exist in some deformities of altering the position of the scaphoid.

per cent, were rather easily corrected by repeated manipulations and plaster fixation during the early months of infancy but that more than half of the cases had relapsed requiring further treatment. Twenty-five per cent of these had been again manipulated with tenotomy of the achilles, plantar structures, and deltoid ligament and had been improved. Others, in spite of repeated manipulation and tenotomy of all resisting structures, reached the age of 3 or 4 years with a noticeable deformity, an awkward gait and an inability to run.

Nineteen per cent required open operation on the ligaments on the internal border of the foot, freeing the tarsal bones and 10 per cent required subsequent manipulation, tenotomy and fixation after open operation.

The early manipulation with some form of fixation is the generally accepted treatment for clubfoot in infants and should begin at the age of 1 or 2 weeks and be rapidly carried to complete correction.

Whether the fixation is by adhesive plaster splints or plaster casts is not as important as that all the manipulations be done by the same person, who has a very definite idea of the component parts of the deformity and the amount of force necessary to correct the deformity.

This procedure must be supplemented by lengthening of the plantar structures and tenotomy of the achilles tendon in many cases to complete the correction.

From recent experiences I am convinced that no manipulation is able to replace the scaphoid in some of the cases, and blind cutting can only by sheer luck regularly reach the ligaments, owing to the altered shape and position of the joints. Another observation is that a relapsed clubfoot is in reality a partial correction of the original deformity, which is hidden by a new position.

After repeated manipulations, the scaphoid at operation was found still in close contact with the sustentaculum. The head of the astragalus was still prominent on the dorsum of the foot and the os calcis was inverted. This must account for many failures to correct the deformity. In other words, relapsed cases are those in which the relations of the astragalus, scaphoid and os calcis, in spite of manipulation and tenotomies, remain the same as they were originally or only slightly altered.

A cured clubfoot should have a normal appearance and present a hollow on the dorsum of the foot in the position formerly occupied by the head of the astragalus, and the patient should be able voluntarily to evert and dorsiflex the foot well beyond the right angle.

It is not my purpose in this paper to attempt a discussion of the treatment of all types of clubfoot or to dwell on the various methods in use for all ages from infancy to adolescence and adults, but to limit the discussion to the relapsed foot of early childhood, shortly after the walking age in an otherwise normal child.

My attention was called to the following operation, originated by Mr E P Brockman¹ in London and, while it is too early to report the final result in many of my cases, I feel that it has made a decided improvement in the results decreased the number of severe manipulations, shortened the long periods of plaster fixation, and prevented a number of unnecessary tenotomies. A marked increase in the ability of the patient to evert and dorsiflex the foot voluntarily was also noted. Brockman bases his operation on his theory that the usual clubfoot is due to a congenital subluxation of the astragalo-scaphoid joint and also that relapse is due to failure to reduce this dislocation (fig 1). My observations coincide with the views of Brockman.

OPERATION

Under an Esmarch bandage a short incision is made over the outer side of the os calcis and all the plantar muscles and tendons are freed from the plantar surface of the os calcis.

Another incision is then made through the skin and fascia along the inner border of the foot. The tibialis posticus tendon and the vessels will be recognized and found in a more forward position, passing straight down instead of in the usual curved position entering the sole of the foot at a right angle. On the posterior side of the tendon and vessels the incision is carried to the os calcis and the remaining plantar structures on the inner side with the origin of the abductor hallucis are freed with a small chisel. It is well to carry this stripping out on the surface of the os calcis to the calcaneocuboid articulation and up to the subastragalar joint.

Vessels and tendons are retracted and the incision is carried to the scaphoid and internal cuneiform bones. The sheath of the tibialis posticus can be opened and the tendon divided if necessary. The insertion of the tibial tendon is free from the scaphoid and reflected with all the structures from the internal inferior surface of the tarsals, exposing the scaphoid and sustentaculum.

By moving the forefoot, one can identify the proximity of the scaphoid and the internal malleolus. All the ligaments on the internal and inferior surface are divided and, if the scaphoid and the internal malleolus are not widely separated, the ligaments on the superior surface of the scapho-astragalar joint must also be divided.

The foot is then manipulated and the forefoot everted. If it is not loosely held in a fully corrected position, the dissection is carried forward on the plantar surface, the attachment of the tibialis posticus being freed from the other tarsal bones, and all resisting ligaments on the superior internal surface of the scaphocuneiform joint, which resist, are also freed. In one case it was necessary to sever the ligaments between the internal cuneiform and the first metatarsal.

For this operation to be successful the dissection must continue until the scaphoid is fully replaced in front of the astragalus and the anterior part of the os calcis moves outward from beneath the astragalus and a space exists between the sustentaculum and the scaphoid and the heel is really everted.

The wounds are closed and a plaster cast extending over the flexed knee is applied with the foot in the best position the circulation will allow but not overcorrected.

Fig 2—Age of x ray visibility from Camp and Cilley of the Mayo Clinic. The astragalus, os calcis and cuboid are visible roentgenographically at birth, the external cuneiform is visible at 1 year, the internal cuneiform is visible at from 3 to 3½ years and the scaphoid and middle cuneiform are visible at 4 years.

Fig 3—Tracing from roentgenogram of M S aged 2 years with relapsed club foot before operation. The scaphoid is not visible.

Fig 4—M S aged 6 years four years after operation. There is a corrected position and development of the tarsal line but the scaphoid is still not visible.

¹ Brockman, L. L. Congenital Cl. Ft. (Tables Equivocal) New York: Wm. Wood & Co. 1909.

In ten days or two weeks the cast is removed and the foot further corrected, if desired. A tenotomy of the achilles is performed now, if necessary, and a new cast applied, allowing the stitches to remain for another two weeks. At the end of the second month the cast is removed, and walking is allowed. Ordinary shoes are worn, physical therapy and instruction in walking are given, and a night splint is applied when necessary.

By gentle dissection the amount of fibrous tissue formed is less than one would suppose from the rather large area exposed. By carrying the incision to the bone and reflecting all the soft tissue *en masse*, one preserves all the main vessels, nerves, tendons and tendon sheaths on both the dorsum and plantar surfaces and free access is had, which allows division of all resisting ligaments.

Unless some extraordinary malformation presents itself, roentgenograms of clubfoot are taken very rarely. Since performing the operation described, I have not been able to get roentgenograms made of all these feet before and after surgery, but I have been fortunate enough to get a series of plates at different ages.

Besides the deformity presented, an interesting and peculiar finding has been noted. Admitting that the bones in a clubfoot are usually less developed than those of a normal foot of the same age, I have observed that the scaphoid is far behind all the other bones.

According to Camp and Cilley,² the os calcis, astragalus and cuboid are normally visible in roentgenograms

at birth (fig 2). The external cuneiform presents itself at 1 year of age, the internal at 3½ years and the middle cuneiform and scaphoid at 4 years of age. In some of these patients with clubfoot who were operated on, the scaphoid was not visible at 6 years of age, although the other bones were roentgenologically visible.

Especially was this impressive when a unilateral case showed a well formed scaphoid in the normal foot and no sign of one in the roentgenogram of the operated foot. Surgery in this case was done at 2 years of age and the roentgenograms were taken at 6 years.

Fig. 5—M. B. aged 9 years with relapsed clubfoot before operation.

The thought comes to mind whether the delayed ossification is caused by manipulation and operative procedures or whether sometimes in clubfoot the delayed ossification and relatively soft structure is a cause of or agent in relapse when closed methods were thought to be efficient. From the few cases of which

I have roentgenograms it is not possible to draw any definite conclusions. This delayed ossification, however, may account for the relatively shorter internal border in clubfoot and may also fail to give enough wedging action to hold the forefoot outwardly rotated at the midtarsal joint.

As yet it has not been possible to follow these cases long enough to watch the development of the ossification with a series of roentgenograms, but it will be an interesting complementary observation. However, it is

known that the case is not a congenital absence of the scaphoid because the cartilaginous body of this bone has been observed in each case at operation.

CONTRAINDICATIONS

The small size of the region to be explored and the large amount of fat in the sole of the foot of infants are definite contraindications against open operations before 3 years of age. These difficulties are absent in older children.

Open approach is very difficult and often impossible in the very rigid foot, such as seen in arthrogryposis with extreme shortening of all the soft parts on the inner border of the foot, as the internal cuneiform and first metatarsal may entirely hide the scaphoid and the small size of these structures prevents the replacement of the head of the astragalus.

Fig. 6—M. B. aged 11 years two years after operation. There is a reduction of the scaphoid on the astragalus and development of the tarsals.

CONCLUSIONS

Early manipulations cure about half of the cases of clubfoot in infancy.

Repeated manipulation and tenotomy of the achilles and other tendons and plantar structures will correct many more cases.

There remains 19 per cent of the cases which are rigid and, after repeated manipulations, show some improvement in appearance, but the head of the astragalus is still palpable in dorsiflexion and the heel held in some varus. This is the type of foot which is not fully corrected and readily relapses. The subluxation of the astragaloscaphoid joint has not been reduced.

The open operation is much to be preferred to repeated severe manipulations with repeated tenotomies or osteotomy in these relapsed cases, as one can by this method very definitely loosen the tarsal bones and place the forefoot on the head of the astragalus and at the same time replace the os calcis and evert the heel.

Osteotomy of the tibia with rotation of the distal fragment in relapsed cases produces one deformity to cover another and, while improving the appearance some, adds little to the function of the foot.

As bone operations rarely give a really satisfactory result and should seldom be done before puberty, this

ligament operation finds its greatest field of usefulness in the relapsed rigid clubfoot of early childhood

I feel that open operation, except in the very young and very rigid feet, has been of great assistance in correcting the relapsed clubfoot of early childhood

421 Michigan Street

ABSTRACT OF DISCUSSION

DR HAROLD A. SOTFIELD, Chicago I have been using an incision rather similar to Dr. Chollet's since 1930 and to the present have used it in forty-seven cases. The incision is made on the inside of the foot rather than the lateral side and extends from the medial malleolus down over the internal cuneiform bone. Often a second incision is made along the plantar surface to free the plantar fascia. After the plantar structures are loosened the internal cuneiform is separated from the scaphoid, and the scaphoid from the astragalus. Then the scaphoid is rotated laterally around the head of the astragalus. This rotation seems to have a great deal to do with the correction. In the forty-seven cases I have had four relapses so far. There is a supplementary treatment which I often employ after the operation. This consists of a plaster cast applied in two sections, extending from above the bent knee to the toes. The parts are separated just below the ankle joint and felt is placed along the edges. Incorporated in the cast are two small strips of aluminum, one extending across the metatarsal region, the other

in seeing the results that he obtained. These results were well demonstrated at a meeting in Toledo two years ago. These feet can be well corrected but the condition will recur unless proper after-treatment is maintained. I found that in these cases the after-treatment has to be maintained for quite a long time by the use of plaster-of-paris walking apparatus or corrective shoes. The correction in which function is good and in which the form seems all right I think should be checked up by roentgenograms following the correction at intervals of six months, nine months or a year or two years later, to make sure that the deformity does not recur.

LOCAL DIATHERMY IN PERIPHERAL CIRCULATORY DISTURBANCES

SAMUEL PERLOW, M.D.

WITH THE TECHNICAL ASSISTANCE OF KATHRYN BLAKELY
CHICAGO

Heat is a time honored measure in the treatment of peripheral circulatory disturbances of the extremities. It is one of the best known means of relieving pain and limiting the spread of gangrene and ulceration. Diathermy, as it is now known, was recommended in the treatment of articular and circulatory disturbances by Nagelschmidt in 1897, after he demonstrated that high frequency currents produced heat when passed through the tissues.¹ It has been shown that it is possible to produce deeper heat with this agent than by any other means.² Heat applied externally cannot penetrate deeply because of the skin resistance and because the circulating blood removes it rapidly. The heat of diathermy is produced within the tissues faster than the heat regulating mechanism can dissipate it. The immediate effect produced is a transitory stimulation of the nervi nervorum followed by a quickened arterial and capillary circulation, and by a vasodilatation of the blood and lymph spaces. This is followed by an increased vascularity between the poles.³ Kovacs³ lists the clinical actions of diathermy as (1) active arterial hyperemia and hyperlymphemia, (2) local relief of pain by the heat acting on all the nerve endings, (3) antispasmodic action, and (4) bactericidal action.

In the peripheral circulatory clinic of Michael Reese Hospital all patients with arterial disturbances of the lower extremities are placed on a routine management for a three to four weeks period of observation. The regimen consists of rest, contrast baths and Buerger's exercises. Tobacco smoking is stopped, and local diathermy treatments of one hour each are given twice a week to each extremity. If the patient begins to improve, we continue this treatment. If there is no improvement, we resort to the more radical forms of therapy, as typhoid vaccine or hypertonic salt solution intravenously, nerve blocks and the like. We have found that almost all cases of arteriosclerotic ischemia without gangrene, and a few of the mild cases of thrombo-angitis obliterans, are improved by this management both subjectively and objectively.

PROBLEM AND METHOD

This investigation was undertaken to determine the value of diathermy and the part it plays in the improvement. A series of various types of cases was tested.

on the back of the calf about 2 inches below the knee. Only about 1 inch of each end of the strips extends outside the plaster and they are bent hook shaped. To these hooks elastic bands are attached and by varying the position of the bands almost any direction of pull can be applied. The cast and bands are put on immediately after operation and the foot is suspended from a metal cradle in the bed. The patient, of course, must remain recumbent or in a half sitting position. The elastic traction exerts a constant easy pull and gradually stretches the tight structures, bringing the foot into an overcorrected position. When the desired position is obtained a solid cast is applied. By exerting the pressure gradually and steadily there is a minimum amount of trauma to the foot and it is not necessary to subject the patient to radical wrenching and twisting at the time of operation. With the elastic traction the desired position of overcorrection can be obtained in from two to ten days. Previous to employing this method it often took six to ten weeks to get a satisfactory position. Naturally it cuts the time of hospitalization to about one fourth the usual time and the treatment is essentially a hospital procedure.

Dr. FRANK G. MURPHY, Chicago. When I heard about Dr. Chollet's treatment of this type of clubfoot I was interested

Pulsations of the larger arteries were graded, the skin temperatures were taken and histamine skin tests were made to determine local circulatory efficiency before and one-half hour after diathermy was given. The

* Treatment consisted of diathermy by means of double cuff and plate with a current of 1,000 milliamperes. Before treatment was started the patient had pains in the calves of the legs and in the ankles after walking one or two city blocks. After two months of diathermy he was able to walk six blocks before the pains started.

Cuff and plate electrodes were used, the cuff was placed around the thigh just above the knee and the plate under the anterior half of the foot and the toes. The two extremities were treated at the same time by using double electrodes. A current of from 750 to 1,000 milliamperes was employed in most cases. In a few debilitated individuals, 600 milliamperes was all that could be given without discomfort.

The controls for this investigation were the previous histories of the patients tested. In each case there was a history of long standing disability in spite of various types of treatment. The results are summarized in tables 2 and 3.

In order to determine whether the rise in the skin temperature and the improvement in the skin reaction to histamine were due to the direct action of the diathermy in heating the tissues or whether they were due partly to relief of the vasospasm which accompanies all types of arterial disease, a few individuals with normal circulation were tested. The results are shown in tables 2 and 3.

COMMENT

The immediate results of the diathermy are as follows. In cases of arterial disturbance, 59 per cent of the nonpulsating vessels were made to pulsate, and the pulsations of 45 per cent of all open vessels were improved as compared with improvement in only 20 per cent of the vessels in normal subjects. The average maximum rise in the skin temperature in cases of circulatory disturbance was 53 degrees C, as compared with 37 degrees C in the normal subjects, and the average rise in the skin temperature of the big toe was 36 degrees C, as compared with 22 degrees C in normal persons. The peripheral circulation as determined by the skin reaction to histamine was improved

* Only the popliteal, dorsalis pedis and posterior tibial arteries were considered here because they were in the area given diathermy. Two subjects (10 and 11) had one extremity only.

patients were given diathermy treatments twice each week for a period of two months and were then tested again (table 1). No other form of therapy was given during this time. In all cases the extremities were exposed to the room temperature for twenty minutes before the initial readings were made. The diathermy was administered with the patient in a sitting position.

in 65 per cent of the cases of arterial disease and in only 25 per cent of the normal cases.

The rise in the skin temperature was most marked about the foot and ankle. There was no noticeable injury to the atrophic skin by the rise in the skin temperature. With all these changes locally the general effect was negligible as was shown by the slight rise

in the mouth temperature or no change at all in some of the cases. This is of considerable importance in view of the fact that many of these cases are debilitated and show some myocardial degeneration.

The opening of 58 per cent of the closed vessels in the cases of arteriosclerosis is definite evidence that there is a high degree of vasospasm in those cases to an extent not previously known. This fact and the greater rise in temperature in the cases of circulatory disturbances in the normal subjects indicate that relief of vasospasm is one of the means by which diathermy improves the circulation and heats the tissues.

TABLE 3—Summary of Results from Table 2

Diagnosis	Closed Vessels Opened per Cent	Open Vessels Improved per Cent	Average Temperature Rise		Histamine Test Improved on Dorsum of Foot per Cent
			Max. mm C	Big Toe C	
Thrombo-angitis obliterans	53	36	5.2	3.6	70
Arteriosclerosis	58	50	5.1	3.1	62
Raynaud's disease	100	70	6.5	5.7	50
Average in arterial cases	59	45	5.3	3.6	60
Normal subjects		20	3.7	2.2	20

Most of the subjective effect of the diathermy was temporary and lasted from twenty-four to forty-eight hours, but after two months of treatment there was permanent improvement both subjectively and objectively in six of the eight cases of arteriosclerotic ischemia and in one of the ten cases of thrombo-angitis obliterans. Other investigators have had similarly good results with diathermy in cases of arteriosclerosis.

The reasons for the permanent improvement in the arteriosclerotic cases and the excellent immediate but poor permanent results in the cases of thrombo-angitis obliterans may lie in the pathogenesis of the two conditions. Arteriosclerosis is a chronic degenerative condition and the narrowing of the vessels takes place over a period of years. The tissues may have become accustomed to the slow diminution of the blood supply, and slight improvement in the collateral circulation may be sufficient to restore the normal functions. Thrombo-angitis obliterans is a more acute inflammatory disease. New vessels or parts of vessels are continually being thrombosed, resulting in a relatively sudden removal of the blood supply from the tissues. Diathermy produces excellent immediate results in this condition, probably by relieving the vasospasm, but in most cases the disease involves the primary vessels faster than the development of the collateral circulation by diathermy.

The two cases of Raynaud's disease tested showed definite immediate relief of vasospasm, but there was no permanent improvement in the condition.

CONCLUSIONS

There are not enough cases in our series to warrant a comparison between diathermy and other types of treatment in peripheral circulatory disturbances. Our results show that:

1. Diathermy locally is of definite value in the treatment of peripheral circulatory disorders especially in arteriosclerotic ischemia without gangrene.

2. Diathermy improves the circulation largely by relieving vasospasm.

POSTVACCINAL ENCEPHALITIS

PROF. DR. E. GORTER
LEIDEN, THE NETHERLANDS

A study of the different diseases encountered in succeeding centuries is of the utmost importance. It has to overcome tremendous difficulties, which are mostly to be attributed to differences in methods of observation and study. But in part the difficulty lies in the more objective character of the symptoms in certain diseases, and I believe that to this group belongs postvaccinal encephalitis.

Most of the symptoms and the development of this complication of vaccination are so striking that it is extremely improbable that the predecessors of modern clinicians who were much better observers than the latter, overlooked its existence.

I can illustrate this by citing from an old booklet on vaccination, written by a doctor named Ranque and edited in Paris in 1801, what was said concerning the cerebral complications of variolation. This furnishes direct proof that symptoms such as those now observed after vaccination, which occurred after the use of another mode of protection against smallpox, did not escape the attention of medical men.

Ranque spoke of comatose conditions that are often encountered during the period of the fever. On page 33, in describing the technique of incisions, he mentioned the occurrence of terrific convulsions. On page 44 he indicated a method of treatment for cerebral complications, which are often dangerous, this consisted in taking the patients out of bed and placing them in the fresh air.

Chart 1—Temperature curve in case of postvaccinal encephalitis

In typical cases of postvaccinal encephalitis the symptoms are striking. I cite the following observation as an example:

REPORT OF A CASE

On the eleventh day after vaccination on the arm a boy, 3 years of age, presented a rise in temperature to 104 F. He vomited once and was not drowsy or sleepy. The onset was quite sudden although several days before he had been somewhat drooping and low spirited.

On his admission to the hospital three typical crusts were found on the vaccinal lesions on the arm with a group of enlarged lymph nodes in the corresponding axilla. The general impression was not unfavorable. The child was not drowsy. Slight twitches in the right arm were observed, and also a

Read before the Section on Pediatrics at the Eighty-fourth Annual Session of the American Medical Association, Milwaukee, June 14, 1931.

certain degree of strabismus, which was apparently not due to muscular paralysis. Other signs of a cerebral lesion were not distinct, but became so on the second day of his stay in the hospital, the twelfth day after vaccination. Drowsiness developed, with grinding of the teeth and sweating. The Kernig and Brudzinski signs were positive. There was distinct rigidity of the neck. The legs were somewhat hypertonic and the Babinski reflex was present. The EEGs showed no abnormalities.

On lumbar puncture the fluid was under normal pressure (20 cm of water), there was no globulin but the number of

TABLE 1—Monthly Distribution of Cases of Postvaccinal Encephalitis

cells was increased to 180 per cubic millimeter; these were mostly lymphocytes. The sugar content was 0.067 per cent. The blood count was only slightly different from normal: leukocytes, 9,800; lymphocytes, 35 per cent; monocytes, 5 per cent; red nucleated neutrophils, 10 per cent; segmented nucleated neutrophils, 49 per cent; and eosinophils, 1 per cent.

The temperature was high on the first day, but was normal afterward (chart 1).

The course of the disease was favorable. Improvement began on the third day after admission; all symptoms gradually disappeared. Drowsiness was last noted at the beginning of the second week, and on his departure from the hospital the patient behaved normally, showing no sign of a cerebral lesion.

Total	657,101	96	1.5

COMMENT

This case represents a typical form of the disease, although cure was more rapid than usual. In not less than one third of all typical cases of the disease a fatal issue is observed. Symptoms of drowsiness develop into coma, and death results from paralysis of the centers of respiration and circulation. The exact histologic picture of the cerebral lesion is therefore known.

The lesions are not altogether pathognomonic of postvaccinal encephalitis, as Professor Bok and other observers have said, because they are also met with in other forms of encephalitis due to other infections or intoxications, e. g., smallpox, chickenpox, measles and tetanus.

I return now to clinical observations, because it is important to draw attention to the various forms of the disease, to more or less exceptional symptoms and to other clinical peculiarities before entering into a discussion of the pathogenesis.¹

One of the most constant facts with regard to this type of encephalitis is the incubation period. In 108 cases recorded before 1929, this period was strikingly constant, the onset usually being observed on the tenth, eleventh or twelfth day after vaccination (chart 2). It was often related in the history that the child was ill on the seventh or eighth day with fever and agitation but recovered more or less completely, so that the encephalitis was separated from the first period of disease by several days of relative well-being. This course of events is, however, not seen regularly, because either the initial fever disappears on the seventh or eighth day or it progresses without interruption into the fever due to encephalitis.

Among the symptoms headache was rather frequent and was often associated with vomiting. Drowsiness

Chart 2—Incubation period of postvaccinal encephalitis

and even coma were often observed, whereas convulsions did not occur as frequently. Often meningitis was indicated by rigidity of the neck and a Kernig sign, and examination of the spinal fluid frequently confirmed the diagnosis of meningeal invasion by the finding of a high cell count, elevated pressure or a high sugar content. Paralysis of the ocular muscles or of the facial nerve or disorders of speech and deglutition were occasionally observed, whereas in other cases paralysis of the muscles of the legs and arms was present. Also in cases without paralysis the Babinski and similar reflexes were often seen, and the tendon reflexes frequently showed some abnormality.

The disease has a rather unfavorable prognosis. Of the well-developed cases almost one third have a fatal issue. Death usually occurs within a week after the onset of the disease.

In striking contrast with the bad prognosis as to life is the good prognosis with regard to sequelae. It is most exceptional if symptoms of a cerebral lesion are seen after the disappearance of acute symptoms, and

¹ Data are from the report of a special committee.

there is some reason to doubt the diagnosis of postvaccinal encephalitis in the rare cases in which a defective intelligence or hemiplegia remains after a disease resembling postvaccinal encephalitis. These characteristics are completely different from those of other forms of encephalitis or meningitis, whereas they are typical of a disease like tetanus.

EPIDEMIOLOGY

Monthly Distribution—It was interesting to study the course of postvaccinal encephalitis and to see how it spread among Dutch children of preschool age and older.

March 1927	10	6/26 A

Whereas atypical or doubtful cases of the disease possibly occurred earlier, the first definite case with all the typical symptoms was observed in June, 1923. This was the only case recorded that year. In 1924 there were seven cases, two of which occurred in March, the month when a great number of vaccinations were performed, owing to the fact that at the beginning of April children were sent to school for the first time and were obliged, at that time, to show a certificate that they had been vaccinated against smallpox.

In 1925 a real outbreak of the disease occurred in March when seventeen cases of the twenty-nine recorded that year were seen. This number is far too great to be explained by the greater number of vaccinations; it is as a matter of fact, four or five times as large as it should be.

In 1926 only five cases of the total of twenty-four occurred in March but in 1927 ten cases were seen during March, and this number is about twice the average in relation to the number of vaccinations. The numerous cases of encephalitis in 1927 (thirty-six) were more evenly distributed although April and July showed somewhat more than the average number.

TABLE 4—Instances of More Than One Case on the Same Date in the Same Village

Cases	Province	Date	Strain
1 and 16	Cucklers	March 7, 1927	15/24 H
18 and 20	North Holland	March 10, 1925	15/24 H
40 and 41	Irkland	March 2, 1926	20/25 A
61 and 62	South Holland	Feb. 17, 1927	31/26 R
70, 72 and 73	Cucklers	March 27, 1927	6/26 A
81, 84 and 85	Zeland	July 9, 1927	12/27 H

A decrease in the number of cases occurred during 1928 entirely owing to the fact that compulsory vaccination was abandoned.

Thus during the period studied there was an irregular distribution of cases over the months of the year, which is not explained by the difference in the number of vaccinations.

Local Factor—The same irregularities were observed in the distribution over the different parts of The Netherlands although with the exception of Groningen and South Holland the whole country obtained the vaccine from the central institute in Amsterdam. There was a certain predilection for some provinces whereas others were almost or completely free from cases. The

number of cases in certain provinces was from two to three times the average, whereas in others it was out of all proportion to the number of vaccinations.

Another interesting point is that age appeared to have some influence, as cases were rarer among children up to 2 years of age than among older children. It is, however, difficult to say whether this factor was real, because the total number of children under 2 years of age was very small, and a diagnosis of encephalitis in this group offered greater difficulties.

Type of Vaccine—The list of irregularities should be completed by a survey of the encephalitis occurring in children vaccinated with different strains of vaccine. The record of different strains of vaccine used all over the country gives a rather irregular distribution of cases.

A special strain (15/1924) caused an unusually large number of cases, but it was used only in March, 1925, and was the only vaccine employed during that period. Vaccination with strain 6/1926 also was followed by encephalitis in a rather large number of instances, this vaccine was distributed only in March, 1927, and was the sole vaccine used.

It is necessary to mention also that in six instances more than one case occurred on the same day in the same small village after vaccination with the same vaccine. But one must not overlook the fact that most of

TABLE 5—Influence of Pigment on Reaction to Vaccination*

Nonirradiated	6.2	+++	++	±	46	6

* Results of Van der Schaaf.

these cases occurred during March 1925, and March, 1927 (or July, 1927), which are the periods of high incidence of the disease.

From the last-mentioned facts there seem to be two possible conclusions:

1 The irregularities in the distribution of cases are due to local and seasonal influences.

2 The irregularities result from the use of a more dangerous vaccine during the months and in the regions of highest incidence.

It is impossible to decide between the two possibilities, notwithstanding a large amount of investigation on the pathogenesis of this type of encephalitis. In favor of the first hypothesis is the fact that cases of encephalitis have developed following the use of vaccines imported from other countries.

Differences in the frequency of the disease according to locality and time are met with in many other infectious diseases and are ascribed by some observers to a lack of sunshine. The predominance of cases during March would fit in with this explanation. Also some experiments performed in my laboratory by Dr. Van der Schaaf tend to support this view.

In comparing (naturally or artificially) pigmented animals with white animals in regard to their local reaction he found that the maximum of the reaction was more quickly reached, local edema and central necrosis were much less pronounced, generalization was less frequent and immunity was obtained at an earlier period in black rabbits and in rabbits whose skin had been

pigmented by exposure to ultraviolet radiation than in white nonirradiated animals. Such experiments might indicate a relation between pigmentation and severe infections or complications.

But the other hypothesis, that local and seasonal irregularities result from a stronger tendency of certain strains than of others to produce encephalitis, has an equal right to careful consideration.

I have often studied the difference between various lots of vaccine in regard to the production of sterile encephalitis in rabbits. Some strains easily produce

TABLE 6—Influence of Staphylococci on Results of Vaccination *

this encephalitis following direct injection into the brain, whereas others do not. The different types of vaccine show other differences in behavior in animal experiments. These differences are of the same order as those noted in the study of the influence of pigmentation. There is some reason to believe that part of them are due to the association of living staphylococci with the vaccine. These organisms have, indeed, a distinctly beneficial influence on the type of reaction of some strains of vaccine, such as neuroLapine.

But the question arises, do these differences in experimental results correspond to the variation in the

TABLE 7—Results Showing No Influence of Dead Staphylococci, Intravenously Injected Staphylococci and Pus on Reaction to Vaccination *

occurrence of encephalitis in vaccinated children? This is not known because the number of children who have been vaccinated with the "mild" type of vaccine is too small.

At present the problem is based more or less on whether one believes that vaccination itself is the direct cause of the encephalitis or that the encephalitis is due to a revival of a latent virus.

The question can be formulated therefore, clinically as follows: Is postvaccinal encephalitis comparable to herpes—that is, is it due to a virus always present in the body and acting only when another disease has prepared the ground—or is it comparable to the nephritis complicating scarlet fever?

I should like to advocate the last theory. Clinicians are familiar with the idea of a complicating organic disorder in an infectious disease without the assumption that a secondary virus is always present as a causative factor. There is no reason to make an exception of postvaccinal encephalitis unless it can be proved that another virus exists, as in herpes. Like many other complications, encephalitis can follow several infections (e. g., measles), and the lesions found in this form of the disease are much like those of the postvaccinal form.

I do not see any reason to admit a different mode of causation for postvaccinal encephalitis than for a large group of other complications observed every day in the clinic.

A certain difficulty is that vaccinal virus is hardly ever found in the cerebrospinal fluid in postvaccinal encephalitis. However, one may cite many examples of severe intoxication of cerebral centers in which autopsy does not reveal the toxin locally, e. g., tetanus or diphtheria toxin. Moreover, Herzfeld recently succeeded in tracing vaccine virus in the spinal fluid of several children with postvaccinal encephalitis. It was not found in the cases reported here.

In my opinion one is as fully informed as to the causation of postvaccinal encephalitis as to that of other complications of infectious diseases (purulent meningitis, nephritis), etc., however, knowledge of these complications is incomplete.

HEMOCHROMATOSIS

REPORT OF A CASE

RICHARD GOTT, JR., M.D.
LOUISVILLE, KY.

Hemochromatosis is a chronic disease characterized by the presence of large quantities of hemofuscin and hemosiderin in the tissues, particularly in the liver and pancreas. The iron in this pigment is apparently of both endogenous and exogenous origin. The exact mechanism of this dysfunction of iron metabolism is, as yet, not known. Mallory¹ has produced a pigment cirrhosis of the liver in animals by means of the prolonged administration of copper salts and also finely divided metallic copper. In a large number of human cases there has been a history of chronic copper poisoning either through occupational contact or through the prolonged ingestion of beverages or foods containing copper.

The following case has been under observation for almost six years, during which time some interesting features have been observed, particularly those associated with the diabetic manifestations.

REPORT OF CASE

A white man, aged 42, single, a cabinet maker, admitted to the Louisville City Hospital, Jan. 10, 1927, complained of weakness, excessive thirst and polyuria of three weeks' duration. His weight had fallen from 140 to 120 pounds (63.5 to 54.4 Kg.) during this time. A few days previously his appetite had become poor and a headache had developed. His previous health was described as good, although he had been bothered intermittently for several years with mild attacks of indigestion.

From the Departments of Medicine and Pathology, University of Louisville School of Medicine.

tion described as "gas in the stomach" and "heartburn." He stated that he did not use alcohol, and nothing unusual was discovered concerning his habits.

The patient was well developed but poorly nourished and looked his stated age. His respirations were increased in depth and there was an acetone odor to his breath. His temperature was 98 F, pulse 80, respiration rate 26, blood pressure 90 systolic and 60 diastolic. There was slight deviation of the nasal septum. His upper teeth had all been removed. The lower teeth were carious and the gums were infected. The liver was not described as enlarged, although the subsequent course and observations indicate that it probably was. No abnormality in the appearance of the skin was described. The urine was strongly positive for sugar, acetone and diacetic acid. The blood sugar was 0.248 per cent and the carbon dioxide combining power of the blood was 31 volumes per cent. The red blood count was 3,800,000 and hemoglobin, 75 per cent. The white cell count was 6,200, with a normal differential count.

The acidosis responded readily to treatment with insulin and sodium bicarbonate. Considerable difficulty in stabilizing the blood sugar was encountered. It usually varied from 0.2 to 0.3 per cent, and the urine was frequently positive for sugar. Attempts to lower the blood sugar level further invariably resulted in insulin reactions, which were corrected promptly by dextrose given either by mouth or intravenously. During his stay in the hospital a superficial infection of the left hand developed, which responded readily to treatment. He was discharged April 18, on a maintenance diet, receiving 26 units of insulin daily.

Some phases of his disease were encountered during most of his subsequent admissions. The same difficulty in stabilizing the blood sugar that has been mentioned was always encountered. The blood sugar was as high as 0.465 per cent, but usually varied from 0.2 to 0.3 per cent. His acidosis was always corrected over a period of from six to twenty-four hours, requiring from 100 to 300 units of insulin, depending on the severity of the acidosis. The acidosis responded promptly to therapy when insulin was used alone or when it was used in conjunction with sodium bicarbonate. His weight remained near 120 pounds. The red blood cell count varied from 3,450,000 to 4,250,000, and the hemoglobin from 70 to 80 per cent. The urine occasionally contained a few pus cells. Kidney function was normal for dye elimination.

The blood Wassermann reaction was negative. The maintenance diet consisted of 40 Gm of carbohydrate, 70 Gm of protein and 230 Gm of fat. He followed this diet fairly well and took the amount of insulin that had been recommended at the time of discharge, however, he did not cooperate in returning to the diabetic clinic and would come to the hospital only when in considerable difficulty.

His remaining teeth were all removed during subsequent hospitalization.

He was admitted to the hospital again, September 19. He had been unable to obtain insulin during the preceding two weeks and on admission was in moderately severe acidosis. The examiner now recorded that the liver was enlarged almost to the umbilicus; this enlargement was present to about the same degree on all later admissions. The skin was described as bronzed especially in the region of the neck and shoulders. This bronzing was the subject of considerable discussion during later visits. It was felt by some members of the staff that there was a noticeable decrease in the degree of pigmentation during later admissions; in fact on the final admission it was difficult to say that there was any abnormality at all in the appearance of the skin.

Roentgen examination of the chest now showed some increase in lung markings; this was thought to be indicative of chronic fibroid tuberculosis. No clinical evidence of activity could be demonstrated. Roentgen examination of the gastrointestinal tract was negative. His course was uneventful following the correction of the acidosis and he was discharged Feb. 24, 1928, receiving 57 units of insulin daily.

About one week prior to his third admission March 12 a head cold developed. Four days later pain began in the left ear and it began to discharge on the day of admission. He was mildly acidotic and pus was flowing through a perforation in the left ear drum. The drum was incised and his condition improved.

On the thirty-eighth day of hospitalization a tender area developed in the right gluteal region, which was thought to be a beginning abscess. This subsided, however, and incision was not necessary. On the forty-seventh day of hospitalization, pain again developed in the left ear, and incision of the drum released serosanguineous fluid. The incision had to be repeated a week later, similar fluid being obtained. During the next two weeks he had a low grade fever and tenderness developed over the left mastoid. Roentgen examination revealed destruction of these cells. A simple mastoidectomy was performed, May 3. Cultures from the middle ear and mastoid yielded *Streptococcus haemolyticus* and *Staphylococcus albus*. His postoperative course was uneventful and he was discharged, September 16, receiving 45 units of insulin daily.

Ten days previous to his fourth admission Jan. 7, 1929, a head cold and pain in the right ear developed. The ear began to drain the following day. Examination revealed a perforation in the right ear drum through which serosanguineous fluid was flowing. His diabetic condition was satisfactory. The ear drum was incised, and the patient's general condition improved. He was discharged, February 8, receiving 51 units of insulin daily.

He was readmitted, July 18, complaining of a watery diarrhea of three days' duration. He had eaten little and taken no insulin during this time. He was moderately acidotic. The diarrhea subsided in six days, the stools were watery and foul but contained no blood, mucus or pus. Culture of the feces produced no pathogenic organisms. He was discharged, August 6, receiving 45 units of insulin daily.

August 10, he was readmitted in a mild insulin reaction. His course was uneventful and he was discharged, September 13, receiving 45 units of insulin daily.

Two weeks previous to his seventh admission, Nov. 10, 1930, pain and swelling had developed in the right knee following a slight injury. Roentgen examination revealed changes consistent with infectious arthritis. The knee improved slowly and after six weeks he was allowed to bear weight on it. He was discharged, Jan. 13, 1931, receiving 45 units of insulin daily.

The patient's eighth and final admission was on Dec. 10, 1932. Ten days previously he had contracted a cold and three days later pain and discharge developed in the right ear. He had become steadily worse, and during the two days prior to hospitalization he had eaten little and taken no insulin. He was toxic and in moderately severe acidosis. Pus was flowing through a perforation in the right ear drum. Physical changes at the base of the right lung were consistent with pneumonic consolidation. The acidosis was corrected without difficulty, and the following day his condition seemed much improved. He grew worse during the following two days, however, and died on the fourth day of hospitalization.

AUTOPSY

There was no bronzing of the skin.

The left pleural cavity contained 100 cc. of seropurulent fluid, the right one 250 cc of similar fluid.

The heart muscle was light colored and soft. The left coronary was markedly sclerotic with atheromatous plaques. The left anterior branch was almost occluded. The papillary muscles were atrophic. Sections revealed some sclerotic plaques with a few hypertrophic muscle fibers at the periphery. The larger vessels showed some lipid deposit with hyperplasia of the connective tissue.

The left lung weighed 720 Gm, the right lung weighed 1,200 Gm and was reddish. The increase in weight was due to edema and consolidation especially in the posterior portion and more marked on the right. Sections revealed the air spaces completely filled with recent inflammatory exudate consisting of fibrin leukocytes, serous fluid and some blood. Sections taken from the upper right lobe showed areas of caseous necrosis surrounded by a dense scar tissue infiltrated with lymphocytes, plasma cells and a few endothelial cells. There was an occasional foreign body giant cell. The pleura was covered by a recent firm fibrinopurulent exudate.

The mucosa of the stomach and bowel was slightly brownish. In sections taken from the stomach and upper part of the small bowel the surface epithelium appeared sloughed so it could not be studied. In the deep part of the glands in which the

epithelium was preserved there was a dense deposit of brown pigment in the cytoplasm. A few connective tissue cells of the stroma were similarly pigmented but the leukocytes were not.

The weight of the liver was 1,950 Gm. Just beneath its capsule some dark brown pigment was noted, scattered diffusely. A sectioned surface revealed an abundant amount of similar brownish black pigment. There was some nutmeg mottling. Sections revealed atrophy of the liver cells about the central veins with some sclerosis. There was an abundant deposit of dark brown pigment found between the liver cells, in the cytoplasm of the endothelial cells and also in the liver cells.

The lymph nodes of the mediastinum and also those about the pancreas were slightly enlarged and brownish. Sections revealed an abundance of pigment similar to that found in the liver, especially in the lining cells of the sinuses and in endothelial cells that had infiltrated the lymphoid tissue.

The weight of the spleen was 200 Gm. It was definitely browner than normal and firm in consistency. The capsule was thickened and cartilaginous. Sections revealed an increase in connective tissue with a moderate amount of blackish brown pigment deposited in the cells lining the sinuses and also in endothelial leukocytes.

The pancreas weighed 35 Gm. It was a chocolate brown and slightly firmer than normal. Sections revealed an abundant deposit of brownish black pigment in between the epithelial cells and also in the cytoplasm of many of the cells of the acini. Islands of Langerhans were found with great difficulty. Many of those recognized were small and atrophic. In the islet cells there was an abundant deposit of brown pigment. In localized areas there was some fibrosis about the islets and also about the acini. There seemed to be more pigment however, in the portions which were not fibrotic. Occasional islets were seen which were surrounded by a zone of scar tissue.

Sections of the suprarenal revealed an abundant deposit of brownish pigment in the epithelial cells and also in the stroma but it was not recognized grossly. There was some scarring of the stroma.

The kidneys were normal in weight. The capsules stripped readily and were slightly brown. Sections revealed cloudy swelling of the epithelial cells and a slight deposit of brownish pigment in the stroma.

Sections of the brain revealed no pigmentation, only swelling of the nerve cells.

Skin sections did not show pigment deposit.

Smears and cultures of the cloudy pleural fluid revealed pneumococcus type I in pure culture. The same organism was recovered from the purulent exudate of the middle ears.

Special stains were made of the pancreas, liver and lymph nodes to determine the type of pigment. These stains revealed the absence of hemofuscin and the presence of iron in all the granules. This indicates that the pigment was hemosiderin entirely.

Stains and chemical analysis of the liver and pancreas revealed no copper. The qualitative test for copper consisted of digestion of the tissue and precipitation with ammonium sulphide. Quantitative analysis for iron revealed 20.2 Gm of pure iron in the liver (the normal amount is 0.3 Gm). No excess of iron was found in the lungs.

COMMENT

The patient's disease evidently began some years previously as hemochromatosis. At the time of death there was an abundance of hemosiderin in the liver, pancreas, lymph nodes and suprarenals. Apparently the pigmentation of the pancreas resulted in necrobiosis of the islet cells, so that there was a deficiency of internal gland secretion, resulting in diabetes.

The immediate cause of death was bronchopneumonia, pneumococcus type I.

The disappearance of the skin bronzing which was thought to be observed in this case is unusual. Boland and Curran² have emphasized the lack of dependability

of visible skin changes as a means of diagnosis. Accepting the belief that skin changes are a relatively late manifestation of hemochromatosis, the gradual disappearance of skin pigment as observed clinically and the absence of abnormal skin pigment as demonstrated at autopsy in this case are difficult to explain.

SUMMARY

In a case of hemochromatosis which was under observation for almost six years, diabetes was characterized by insulin resistance, difficulty in stabilization and an unusual susceptibility to infection. It is felt that insulin prolonged the patient's life four or five years.

Clinical Notes, Suggestions and New Instruments

PROGRESSIVE POSTOPERATIVE GANGRENE OF THE ABDOMINAL WALL FOLLOWING APPENDECTOMY

W. I. BROWN, M.D., C. P. BROWN, M.D., AND
J. L. MURPHY, M.D., EL PASO, TEXAS

Cases of postoperative or postinjectional gangrene of the skin of a progressive nature are so numerous in the literature that it is difficult to make a review of one certain variety, owing to the variation of nomenclature.

This report is limited to a progressive gangrene of the skin and subcutaneous tissues of the abdominal wall following laparotomies and chiefly following operations for ruptured appendixes. The latter condition is rather distinctive from closely related progressive gangrene elsewhere and presents so often the same characteristics that it can almost be classed as a clinical entity.

H. D., a man aged 50, a postal clerk in a neighboring city, had had attacks of indigestion characterized by sour stomach, heartburn, constipation and headaches since childhood. The usual cathartics were resorted to with fair results. There was never a definite attack of appendicitis until the present illness. At the age of 24 he was sick two months with inflammatory rheumatism and again for one month at the age of 31. With the last attack he was aware of a heart lesion, and, although it has never troubled him, he was prevented from enlisting in the army in 1918 on this account. The remainder of the past history is irrelevant.

The present illness began as a "bilious attack" about Jan. 1, 1932. There was a dull pain in the right flank, which gradually increased in intensity but did not confine him to bed. On the afternoon on the third day nausea and vomiting appeared and lasted until midnight. There was slight fever. The pain and tenderness never localized over the appendix region to the extent of justifying a definite diagnosis. Intestinal influenza was suspected by the local physician. On the seventh day the patient was up and about. On the twelfth day the fever and pain returned and at this time a mass was felt in the region of the appendix. The pain and tenderness was now localized at McBurney's point.

A local surgeon operated and found a definite walled off abscess with the greater portion of the appendix sloughed away. The stump of the appendix was removed and a rubber drain was used. Convalescence was uneventful until the fifth postoperative day when the edges of the skin around the rubber drain began to turn a dusky red and later became dark. This necrosis progressed steadily in spite of various kinds of wet dressings, including boric acid and mercuric chloride. The dressings were very painful and the patient became more and more emaciated. We saw him on the ninth day after necrosis was noted. The ulcer then measured $3\frac{1}{2}$ by $4\frac{1}{2}$ inches with the long axis in the line of the incision of the previous appendectomy (fig. 1).

We advised complete excision of the ulcerating area by cautery. By this time the patient had lost 20 pounds (9 kg.) and,

² Boland B. F. and Curran I. F. Hemochromatosis. Two Atypical Cases Occurring in Brothers. J. A. M. A. 97: 379-381 (Aug. 8) 1931.

with an enlarged heart from mitral stenosis, was a rather poor operative risk for such an extensive procedure.

The ulcer base appeared to extend only to the fascia, and exuberant granulations were present. The edge was formed by a strip of necrotic and necrosing skin about 2 cm wide which was undermined and beneath which pus could be easily expressed. More peripherally was an area about 3 cm wide in which the skin was red, indurated and slightly raised above the normal skin. This zone appeared somewhat like erysipelas but not with as well defined a margin. At the region from which the drain was removed there was a depression but no evidence of a fecal fistula. There was no normal skin left at the site of the incision as others have so frequently reported.

After preoperative supportive measures were carried out, the ulcer was surrounded with the electrocoagulation knife, which was kept well outside the red zone into the normal skin. The dissection was carried down to the fascia and the ulcer along with its base removed in one piece, with cautions of further contaminations of raw surface by the pus from the ulcer. The bleeding was controlled entirely by coagulation. This left a denuded area that extended almost to the umbilicus medially, Poupart's ligament inferiorly, well past the anterior superior iliac spine laterally and almost to the costal margin superiorly, with healthy fascia as a base except for a small depression at the site where the rubber drain had been (fig 2).

This area was further cauterized. A gauze dressing saturated with an ointment composed of 5 per cent boric acid and 5 per cent zinc oxide in petrolatum was applied and this was covered with an electrical pad continuously. In a few days, healthy granulations appeared. On the tenth day, following forty-eight hours of hot boric acid compresses, the ulcer was covered with skin grafts.

There were two small recurrences of necrosis at the upper border of the wound, owing to the fact that we had not cut far enough out into the normal skin at these points. These were easily controlled by touching them with the cautery.

The patient's general condition and outlook improved almost immediately after the excision of the ulcer, but on the sixteenth day following the excision of the ulcer convalescence was interrupted by intestinal obstruction and auricular fibrillation. Enemas and turpentine stupes would not relieve the obstruction, so that operation was inevitable. The question arose as to where we would make the incision. The midline would be too far from the original abscess, where we felt the obstruction

it gradually granulated over so that five weeks after the excision of the ulcer the patient was discharged from the hospital with only one small area of granulation. He was slow in regaining his weight and strength but this was partially due to his heart lesion. A check up six months and one year later revealed a complete healing of the area. At the site of the last operation there is a weakness of the abdominal wall, but this is without subjective symptoms.

Smear and culture examinations taken from underneath the necrotic edge prior to operation showed gram-negative, motile

Fig 2—After excision

bacilli, gram-positive *Staphylococcus aureus* and gram-positive diplococci. We did not search in the red zone for streptococci, but a microscopic section revealed a marked inflammatory process with extensive polymorphonuclear infiltration.

REVIEW OF THE LITERATURE

Cullen of Baltimore reported the first case of progressive postoperative gangrene of the skin following appendectomy in 1924, or only nine years ago.

Lynn¹ of Baltimore, up to November, 1931, had seen or collected from the literature twenty-one such cases, fifteen in males and fourteen following operation from appendiceal abscess or peritonitis. Ten of the patients were above 45 years of age. The condition is certainly more common following laparotomies, but Christopher and Ballin² each reported progressive gangrene of the skin following thoracoplasty in 1924 and 1931, respectively.

Meleney³ of New York, who probably has done more work along this line than any one else, saw fourteen cases of gangrene of the skin following scarlet fever antitoxin injections in a period of five years. He has also been enlightening on hemolytic streptococcal gangrene of the scrotum and penis. The last two, however, do not seem to be the same type of necrosis as that of the abdominal wall after appendectomies.

As to the etiology, very little is known. The more common organisms found are nonhemolytic streptococci, hemolytic staphylococci and diphtheroids, especially the two former, and usually the streptococci are in the red swollen tissues while the staphylococci are bad at the necrotic margin. Meleney thinks

Fig 1—Before excision

was located while on the other hand we did not wish to cut through the new skin grafts which were just beginning to grow.

Disregarding the latter the incision was made just medial to the original appendectomy wound. Realizing that the grafted area was infected we sterilized the operative field as well as possible with iodine and sewed towels previously saturated in 1:1,000 mercuric chloride solution to the underlying muscles before the peritoneum was opened. The obstruction was corrected and our wound closed as well as possible with skin grafts sutured through muscle, fascia and skin grafts. Considerable sloughing occurred at the site of our wound but

1 Lynn F. S. Postoperative Gangrenous Ulcer of Abdominal Wall. *J. A. M. A.* 97:1497 (Nov. 20) 1931.

2 Ballin Max and Moore P. F. Progressive Postoperative Gangrene of Skin. *Am. J. Surg.* 11: 81 (Jan.) 1931.

3 Meleney F. L. Hemolytic Streptococcal Gangrene Following the Administration of Scarlet Fever Antitoxin. *Ann. Surg.* 91: 267 (Feb.) 1920.

there is a symbiotic relation between these two organisms that is necessary to produce the condition. Gangrene would not occur except for the staphylococci, while the streptococci seem to prepare the way for the staphylococci.

The characteristics of the lesions may be summarized as follows. On the seventh to the fourteenth day after operation, at the skin margins or at the suture holes, the skin becomes dully red and rapidly becomes edematous, dark and necrotic. The edges become undermined and the sloughing tissue becomes white from beneath and exudes a seropurulent discharge. Beyond the sloughing zone is a dark red edematous zone about 1 to 1½ inches in width that spreads at about the rate of 2 cm a day. The original scar may or may not be involved. It may even retain a halo of normal skin about it. The base of the ulcer is very granular, the granulations resting on the fascia but not involving it or the underlying muscles. In no case reported has there been a fecal fistula.

The symptoms are a slight increase in temperature and leukocytosis. Pain may be of a mild to severe burning, especially when the dressings are changed. There is a decided loss of appetite and a progressive emaciation. The depressed emotional state of the patient is quite noticeable.

In the diagnosis, simple staphylococcal abscesses, erysipelas and gas bacillus infection must be considered. In erysipelas the onset is sudden and there is usually a chill. The red area spreads rapidly, but there is no gangrene. In gas bacillus infections the onset is sudden, prostration is marked and there is usually crepitation.

As to the prognosis of the twenty-one cases collected by Lynn,¹ only one patient died of gangrene and the usual course from onset to healing of the grafts varied from two to twenty-two months.

To date, the only satisfactory treatment has been the electrotherm knife, the incision being carried well out into the normal tissue and completely undermining the base. This controls bleeding and helps to prevent further spreading of the infections. All kinds of drug medication, lights and x-ray treatments have been tried but to no avail. About seven to ten days after the ulcer has been removed skin grafting can usually be done. During this time hot boric acid or saline compresses are used.

TOXIC CIRRHOSIS OF THE LIVER DUE TO HYDROCIN (50 PER CENT CINCHOPHEN)

DONALD W. INGHAM, M.D., LANCASTER, PA.

Since cinchophen has been used as an analgesic, particularly in the treatment of arthritis and allied conditions, there have been many contributions to medical literature regarding its toxicity and the signs and symptoms subsequent to the toxic action. A brief concise review of the literature on this subject was given by Weis¹ in 1932. Since that time there have been numerous reports, but the following case fits in well with the cases reported by Parsons and Harding—

REPORT OF CASE

Mrs. F. B., aged 63, was admitted in coma, Sept. 9, 1933, at 4:55 p.m., in the service of Drs. J. L. Atlee, Jr., and Harvey Seiple, in the Lancaster General Hospital. The history was obtained from one of the patient's daughters. The patient had been sick for over a year with arthritis and had been treated by a physician with some degree of improvement, but in June of this year she discontinued supervised medical treatment and on the advice of a friend secured a bottle of Renton's Hydrocin tablets from New York. From that time until the time of admission she had taken three bottles of fifty and nearly all of the fourth. Thursday, September 7, the patient noticed a yellow discoloration of the skin. The next day she had a "pain in the abdomen." A physician was called who advised confinement to bed. Saturday, September 9, she arose and came downstairs and at 9:30 a.m. had a severe pain in the upper part of the abdomen. At this time a hypodermic of morphine

sulphate was given following which she slept. Early in the afternoon the family heard her moaning and was unable to rouse her. Since Thursday the jaundice had become progressively worse. She was then brought to the hospital. It is interesting to note that, when the Hydrocin tablets were begun, the patient had a severe gastric upset consisting of pain in the epigastrium, nausea and vomiting, also that a rash developed over the face and forehead after each dose of the medicine. She finally discovered that, by taking half the prescribed dose, i.e., half a tablet four times a day, these symptoms were not as severe.

The family history was essentially negative.

The patient had always enjoyed good health with the exception of an attack of pneumonia eleven years before and the present condition. There was no history of indigestion or any symptoms referable to liver dysfunction. She had had five pregnancies, the youngest child being now 31. She had had no operations nor accidents.

On examination, the temperature was 103.8 F., the pulse 154 and thready, the respiration rate 16 and shallow and the blood pressure 78 systolic, 50 diastolic. The patient was comatose and showed almost a bronze coloration of the skin. There were macular and papular eruptions over the face and forehead. The hands and feet showed evidence of arthritis deformans. The heart and lungs were normal, the area of liver dullness was decreased.

The laboratory data showed the blood sugar on two successive readings to be 10 and 0, carbon dioxide, 22, urea, 175. The urine was deeply bile colored, showed a heavy trace of albumin, was 4 plus positive for acetone and bile, and showed occasional finely granular casts.

Dextrose and insulin were given at once and stimulation was begun, but despite all treatment the coma deepened, the respiration and pulse became more rapid and the patient died at 11:10 p.m., the day she entered the hospital.

Autopsy showed a small liver weighing 800 Gm. Its surface was studded with milky yellow elevations surrounded by red liver tissue. On section, the liver cut with increased resistance and was flabby. The cut surfaces were red with a patchy distribution of yellow foci of necrosis, which were slightly raised above the cut surface. The liver was tough and not friable. The gallbladder was distended but contained no calculi, and the ducts were patent. Microscopically the liver showed marked destruction of the parenchyma with only small islands of relatively unchanged liver tissue remaining. The remaining liver cells appeared swollen and granular. There was extensive proliferation of bile duct epithelium within the mass of necrotic tissue. Between the islands of liver cells, fibroblastic proliferation was also quite marked. Hemorrhage and phagocytosis of blood and bile pigments were seen throughout.

COMMENT

A report of the Bureau of Investigation³ contains the results of an analysis made by the American Medical Association Laboratory, of "Renton's Rheumatic Tablets." These were found to contain 48.8 per cent of cinchophen. At that time the name was changed to Renton's Hydrocin. Weis reviews eighty-nine cases of hepatotoxicosis, fifty-two of the patients recovered and thirty-seven died. Thirty of these cases were proved by autopsy to be due to cinchophen and its compounds. Harding and Parsons⁴ suggest that the symptoms be divided into four groups: (1) cutaneous manifestations, pruritus, urticaria, and macular and papular eruptions, (2) anaphylactoid reaction characterized by neurocirculatory disturbance, rapid pulse and low blood pressure, (3) gastro-intestinal disturbances including simple aphthous ulcers in the mouth, pyrosis, nausea, vomiting and diarrhea and (4) liver involvement as indicated by jaundice. Weis comments that the toxic manifestations have no relation to the amount of the drug ingested but is probably due to an idiosyncrasy for the drug.

SUMMARY

1. A fatal case of toxic cirrhosis of the liver due to Renton's Hydrocin (50 per cent cinchophen) manifested three of the symptoms outlined by Parsons and Harding.

1. Weis, C. R. Toxic Cirrhosis of the Liver Due to Cinchophen Compounds: Report of Three Fatal Cases. J. A. M. A. 99:2124 (July 2) 1932.
2. Parsons, Lawrence and Harding, W. G. 2d. Fatal Cinchophen Poisoning. Ann. Int. Med. 6:514-517 (Oct.) 1932.

3. Renton's Hydrocin Tablets. J. A. M. A. 96:209-210 (Jan. 17) 1931.
4. Parsons, Lawrence and Harding, W. G. Jr. Am. J. M. Sc. 151:115-125 (Jan.) 1931.

2 In view of the increasing number of reports of toxic cirrhosis due to cinchophen and its compounds, a plea is made for careful supervision in the administration of this drug and immediate discontinuance of the drug when any of these symptoms develop

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY OF THE AMERICAN MEDICAL ASSOCIATION HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT
H A CARTER Secretary

BURDICK ANNIVERSARY MODEL ULTRAVIOLET QUARTZ LAMP ACCEPTABLE

The Burdick Corporation of Milton, Wis., is the manufacturer of this unit. The burner uv-arcc mercury quartz type is similar in construction to that used in other Burdick ultraviolet lamps. The electrodes are sealed in by graded fused seals. Ordinarily the burner does not need to be tilted when starting but merely shaken slightly. When operated on alternating current, it is self rectified. It is available for either alternating or direct current. The reflector is chromium plated interiorly and the wiring is concealed. It is adjustable to vertical and

Emission characteristics of Burdick Anniversary Model Ultraviolet Quartz Lamp

horizontal positions. The adjustable stand permits the lamp to be at any height between 40 and 72 inches from the floor. The entire unit is portable. It is finished in a combination of brown and ivory.

The ultraviolet radiation generated by this lamp is of sufficient intensity to produce a first degree erythema on the average skin in a minute and a half at a distance of 30 inches.

The operating characteristics are as follows:

Alternating Current		Direct Current	
Line voltage	105-12	Line voltage	105-125
Starting amperage on line	8.0	Starting amperage	6.6
Operating amperage on line	5.0	Operating amperage	3
Normal burner voltage across anodes	164	Maximum burner voltage	~2
Operating watts from line	400	Start burner voltage	18
Cathode burner operating amperage	4.6		
Maximum burner equivalent voltage	50		
Start burner voltage	18		

The curve in the accompanying chart shows the emission characteristics of the lamp.

When ordering this unit the type of current available should be indicated.

The Council on Physical Therapy declares the Burdick Anniversary Model Ultraviolet Quartz Lamp eligible for inclusion in its list of accepted devices.

Council on Pharmacy and Chemistry

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

PRELIMINARY REPORTS OF THE COUNCIL

THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING PRELIMINARY REPORT

PAUL NICHOLAS LEECH Secretary

HIPPURAN

Hippuran is a product of the Mallinckrodt Chemical Works, proposed by Swick¹ for intravenous and for oral urography. Its chemical constitution is stated to be sodium ortho-iodohippurate

Hippuran was submitted for consideration by the Council at the request of the Council on Scientific Assembly in order that Dr Swick might present a report on this preparation at a section of the Assembly in Milwaukee.

Sodium ortho-iodohippurate contains 38.8 per cent of iodine, it is said to be soluble in less than its own weight of water and to be stable in aqueous solution. It was chosen as a promising agent for visualizing the urinary tract, in view of the fact that hippuric acid normally occurs in the urine following the ingestion of benzoic acid representing a conjugation of benzoic acid with glycine. Similarly the ingestion of ortho-iodobenzoic acid is said to result in the appearance of ortho-iodohippuric acid in the urine.

Rabbits are stated to tolerate from 2 to 25 Gm of Hippuran per kilogram as 30 per cent solution administered intravenously over a period of ten minutes. Tissues of rabbits have shown no evidence of injury from twenty-four hours to four months after injection. The substance is said to be excreted unchanged in the urine. From 60 to 66 per cent of the injected iodine is stated to be recoverable from the urine in the first hour from 70 to 80 per cent in two hours and from 90 to 95 per cent within eight hours after injection. Hippuran has been used by Swick by the intravenous route in 125 patients and by the oral route in 14. Usually from 10 to 15 Gm has been administered by vein in 40 per cent aqueous solution over a period of five minutes. Swick recommended that the first film

¹ Swick Notes, Surg. Cases & O. 1: 56 (2) (Jan.) 1933

be exposed ten minutes after injection and that two subsequent roentgenograms be taken at twenty minute intervals. No reactions have been noted except a sensation of generalized warmth, such as has been reported with other products used for intravenous pyelography. With a dose of 30 Gm, occasional vomiting has occurred. By the oral route, with doses of from 10 to 15 Gm dissolved in simple syrup, diagnostic pictures are reported to have been obtained 90 and 135 minutes after administration, in seven of fourteen cases.

As the product has not yet been sufficiently widely employed adequately to determine its value, the Council has voted to defer further consideration of Hippuran until more evidence has accumulated with respect to its clinical usefulness, at which time the product will be examined by the A M A Chemical Laboratory.

Committee on Foods

ACCEPTED FOODS

THE FOLLOWING PRODUCTS HAVE BEEN ACCEPTED BY THE COMMITTEE ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION FOLLOWING ANY NECESSARY CORRECTIONS OF THE LABELS AND ADVERTISING TO CONFORM TO THE RULES AND REGULATIONS. THESE PRODUCTS ARE APPROVED FOR ADVERTISING IN THE PUBLICATIONS OF THE AMERICAN MEDICAL ASSOCIATION AND FOR GENERAL PROMULGATION TO THE PUBLIC. THEY WILL BE INCLUDED IN THE BOOK OF ACCEPTED FOODS TO BE PUBLISHED BY THE AMERICAN MEDICAL ASSOCIATION.

RAYMOND HERTWIG Secretary

OMAR WHEAT CEREAL

(WHEAT FARINA WITH WHEAT EMBRYO ADDED)

Manufacturer—Omaha Flour Mills Company, Omaha

Description—A mixture of wheat farina and wheat germ with a small amount of bran.

Manufacture—The farina is heat treated at a low temperature to destroy any insect infestation, the wheat germ is similarly treated separately, at 70 C for fifteen minutes, after which it is promptly cooled. The farina and germ are mixed in formula proportions and automatically packed in cartons.

Analysis (submitted by manufacturer) —

	per cent
Moisture	11.8
Ash	1.3
Fat (ether extraction method)	2.8
Protein (N \times 5.7)	13.3
Crude fiber	1.0
Carbohydrates other than crude fiber (by difference)	69.8

Calories—34 per gram 97 per ounce

Claims of Manufacturer—Essentially a carbohydrate food but containing good body-building proteins, recommended for infant feeding and "smooth" diets. Used as a breakfast food, cooks in from two to three minutes. Excellent source of vitamin B and a good source of G.

FAIRWAY WHITE LABEL BRAND STRAINED BEETS, CARROTS, CELERY, GREEN BEANS, GREEN PEAS, SPINACH, TOMATOES, PRUNES FLAVORED WITH LEMON JUICE, AND STRAINED VEGETABLES WITH CEREAL AND BEEF BROTH

UNSEASONED

Distributor—Twin City Wholesale Grocer Company, St Paul and Minneapolis

Packer—The Larsen Company, Green Bay, Wis

Description—Respectively sieved beets, carrots, celery, green beans, green peas, spinach, tomatoes, prunes flavored with lemon juice, and vegetables (carrots, potatoes, tomatoes, peas, beans, juice, and vegetables) with pearl barley and beef extract prepared by efficient methods for retention in high degree of the natural mineral and vitamin values. No added sugar or salt. These products are the same as the respective accepted Larsen's vegetable

tables and fruits (THE JOURNAL, July 1, 1933, p 35, July 8 1933, p 125, July 22, 1933, p 283, July 29, 1933, p 366, Aug 12, 1933, p 525, Aug 19, 1933, p 605, Aug 26, 1933, p 675, Sept 2, 1933, p 779)

VITAMIN D FORTIFIED PASTEURIZED MILK (150 STEENBOCK VITAMIN D UNITS PER QUART) ADVERTISING OF SOUTHWEST DAIRY PRODUCTS COMPANY

Distributor—Southwest Dairy Products Company, San Antonio and Wichita Falls, Texas

Description—Advertising for bottled pasteurized grade A milk fortified with vitamin D (vitamin D concentrate prepared from cod liver oil), contains 150 Steenbock vitamin D units per quart.

Preparation—The milk complies with the requirements specified by the laws of the state of Texas and the city of San Antonio or other municipalities in which it is distributed.

See this section for Vitamin D Fortified Pasteurized Milk of W J Kennedy Dairy Company, Detroit, for description of fortification with vitamin D (THE JOURNAL, July 1, 1933, p 34).

The milk is pasteurized by the standard procedure of holding at 62 C for not less than thirty minutes, is immediately cooled to 4 C and automatically bottled.

Analysis (submitted by manufacturer) —

	per cent
Moisture	87.0
Total solids	13.0
Ash	0.7
Fat	4.2
Protein (N \times 6.38)	3.3
Lactose (by difference)	4.8

Calories—0.7 per gram 20 per ounce

Vitamin—The vitamin D concentrate used in the preparation of this vitamin D milk and the fortified milk are regularly tested biologically. Clinical investigation shows this milk to be a reliable antirachitic agent.

Claims of Manufacturer—A vitamin D fortified antirachitic pasteurized milk having the natural flavor and food values of standard pasteurized milk.

DAVIDSON'S GENUINE 100% WHOLE WHEAT BREAD

Manufacturer—Davidson Baking Company, Portland, Ore

Description—A whole wheat bread made by the sponge dough method (method described in THE JOURNAL, March 5, 1932, p 817), prepared from whole wheat flour, water, milk, honey, salt, butter and yeast.

Analysis (submitted by manufacturer) —

	per cent
Moisture	35.2
Ash	1.6
Fat (acid hydrolysis method)	4.3
Protein (N \times 6.25)	10.4
Crude fiber	1.9
Carbohydrates other than crude fiber (by difference)	46.6

Calories—2.7 per gram 77 per ounce

Claims of Manufacturer—Conforms to the United States Department of Agriculture definition and standard for whole wheat bread.

CAPITANA FLOUR (BLEACHED)

Manufacturer—Texas Star Flour Mills, Galveston Texas

Description—Hard red winter wheat "1st clear" flour, bleached.

Manufacture—Selected hard red winter wheat is cleaned, scoured, tempered and milled by essentially the same procedure as described in THE JOURNAL, June 18, 1932, page 2210. Flour streams not chosen for patent grades are blended and are bleached with nitrogen trichloride (one ninth ounce per 196 pounds) and with a mixture of calcium phosphate and benzoyl peroxide (1 part to 50,000 parts flour).

Claims of Manufacturer—For general baking.

**EUREKA QUICK-ACTING DOUBLE-ACTING
PURE BAKING POWDER**

Manufacturer—Eureka Products Company, Louisville, Ky

Description—Baking powder containing corn starch, sodium bicarbonate, sodium aluminum sulphate calcium acid phosphate, and a small quantity of dried white of egg

Manufacture—The ingredients complying with definite specifications of purity are thoroughly mixed in formula proportions. Each batch is tested by the laboratory for total carbon dioxide and the neutrality of the residue formed after liberation of the leavening gas, carbon dioxide. The mixture is automatically packed in tins

Analysis (submitted by manufacturer) —

	per cent	
Total carbon dioxide (CO ₂)	15.2	
Available carbon dioxide (CO ₂)	14.2	
Residual carbon dioxide (CO ₂)	1.0	
Phosphorus as P ₂ O ₅	7.9	as P 3.45
Calcium oxide (CaO)	3.11	as Ca 2.22
Sulphuric anhydride (SO ₃)	12.81	as S 5.11
Aluminum oxide (Al ₂ O ₃)	4.12	as Al 2.18
	parts per million	
Arsenic (As)	0.2	
Lead (Pb)	less than 2	

Calories—1.5 per gram 43 per ounce

Claims of Manufacturer—For use in all baking and cooking recipes calling for baking powder. The product and ingredients conform to United States Department of Agriculture requirements as expressed in its definition and standard for baking powder. The two acid reacting ingredients for liberation of the leavening gas because of their different solubilities, produce a "double leavening action" in the dough. The first action releases a portion of the leavening gas in the cold dough, the second releases the remaining gas in the heated dough in the oven.

**RIVAL BEETS, CARROTS, CELERY, GREEN
BEANS, PEAS, SPINACH, TOMATOES,
PRUNES FLAVORED WITH LEMON
JUICE, AND VEGETABLE SOUP
WITH CEREAL AND BEEF
BROTH**

STRAINED, UNSEASONED

Distributor—Rival Foods Incorporated, Cambridge Mass

Packer—The Larsen Company, Green Bay Wis

Description—Respectively sieved beets, carrots, celery, green beans, green peas spinach, tomatoes prunes flavored with lemon juice and vegetables (carrots potatoes tomatoes, peas beans spinach) with pearl barley and beef extract, prepared by efficient methods for retention in high degree of the natural mineral and vitamin values. No added sugar or salt. These products are the same as the respective accepted Larsen's vegetables and fruits (THE JOURNAL July 1, 1933, p 35, July 8 1933 p 125 July 22, 1933, p 283 July 29, 1933, p 366, Aug 12 1933 p 525 Aug 19, 1933, p 605, Aug 26 1933 p 675 Sept 2 1933 p 779)

**MEADS POWDERED PROTEIN MILK
NON CURDLING**

RICHER IN PROTEIN AND LACTIC ACID AND LOWER
IN LACTOSE THAN DRIED WHOLE MILK

Manufacturer—Mead Johnson and Company Evansville Ind

Description—Powdered homogenized modified milk prepared from whole milk cream curd precipitated with calcium chloride and skim milk acidified with U S P lactic acid, relatively richer in protein and lactic acid and lower in lactose than dried whole milk.

Manufacture—High grade milk produced under the Chicago Board of Health Inspection is used. Two thirds of the total volume of the milk to be treated is whole milk, one third is skim milk. The whole milk is boiled and treated with sufficient calcium chloride to cause coagulation of the casein; the curd is excluded in the curd. The curd is allowed to settle and the whey containing the calcium chloride is removed by decantation. The curd is drained and mixed with the skim milk

acidified to 0.75 per cent with U S P lactic acid and homogenized. Steam is injected into the mixture in a closed tank with a vent pipe connected to a condenser and to a vacuum pump. The air is exhausted from the tank, the mixture is rapidly heated to 110 C and after one minute is rapidly cooled by creation of a vacuum in the tank. The heating in the absence of air prevents oxidation of the natural vitamins of the milk. The mixture is again homogenized spray dried and sealed in tins. The process described changes the character of the casein, so that boiling the reconstructed powdered "protein milk" does not cause curdling.

Analysis (submitted by manufacturer) —

MCCORMICK'S BEE BRAND LEMON EXTRACT

Manufacturer—McCormick and Company, Inc Baltimore

Description—Lemon extract containing alcohol, water, and oil of lemon.

Manufacture—Lemon oil from the peel of Italian and Sicilian lemons is expressed by hand clarified by settling, packed in tinned copper cans and exported. At the United States factory the lemon oil is dissolved in 95 per cent alcohol the necessary quantity of water is added, and the solution is clarified by filtration and bottled.

Analysis (submitted by manufacturer) —

	per cent
Alcohol by volume	80
Water by volume	12.7
Oil of lemon by volume	8.0
Citral	0.36 Cm per 100 cc

Claims of Manufacturer—Conforms to the definition and standard for lemon extract of the United States Department of Agriculture.

LOG CABIN SLICED BREAD

Manufacturer—Log Cabin Baking Company, Oroville Calif

Description—A white bread made by the sponge dough method (method described in THE JOURNAL March 5, 1932 p 817) prepared from patent flour water sucrose shortening powdered skim milk salt yeast and a yeast food containing calcium sulphate ammonium chloride sodium chloride and potassium bromate.

NEW FOODS AND DRUGS LEGISLATION

The proposed repeal of the Food and Drugs Act of 1906 as amended, with the enactment of an entirely new law, now commonly called the Tugwell or Copeland Food, Drug and Cosmetic bill (S 1944, H R 6110), has resulted in an unusual—perhaps much to be expected—outpouring of publicity and propaganda from many sources. Periodicals representing the drug, food and cosmetic industries have burst forth with hysterical editorials, special articles, cartoons and similar manifestations of interest indicating extraordinary fears in relationship to the effects of this legislation, if enacted, on the industries that they represent. At the same time, such organizations as represent movements for pure foods and drugs honestly advertised and some of the great leaders in the food and drug industry have indicated their general approval of the measure in most of its aspects. Not only from Washington, and particularly from officials representing the Food and Drugs Administration, but also from Mrs. Franklin D. Roosevelt have come statements indicating that the proposed act may be said to represent an administration measure. By that very fact the Tugwell or Copeland bill is likely to become to some extent at least the law of the land.

The most significant aspects of the proposed legislation concern the extent to which it controls advertising apart from the label and the package. It is no secret that the development of modern advertising, particularly for certain types of drugs, foods and cosmetics, has been so extravagantly elaborated and altogether so grossly exaggerated, misleading and unwarranted as to smell to high heaven in the nostrils of every honest man. The extragovernmental agencies that have been developed in order to assure readers of certain types of advertising copy that some censorship and control have been applied bear witness to the fact. The growth of the various councils and committees of the American Medical Association in the fields of drugs, foods and physical therapy, the growth of such agencies as Consumers' Research, and the innumerable labels and seals that attempt to indicate to readers honesty of manu-

facture and of advertising are evidence of the necessity for some further control over the industries concerned. Unfortunately, these industries have been so unwise as to fail to develop for themselves efficient codes of ethics and methods of enforcement. It seems reasonable to believe that new legislation would have been unnecessary if the industries concerned, and particularly advertising, had seen sufficiently soon the handwriting on the wall.

At the last meeting of the Board of Trustees of the American Medical Association, held in Chicago in November, the publications of the Association were urged to support the principle of the new foods and drugs legislation. The Board of Trustees supports fully the necessity for control at this time of the advertising of foods, drugs and cosmetics but did not consider the time as yet ripe for official pronouncements on the details of administration involved in the new act. Whereas the new legislation is intended to embody all the valuable features of the act which it repeals and to make such additions as may be necessary for regulation of the manufacture, distribution and sale of foods, drugs and cosmetics, it seems in some parts to fall short of this purpose. In the new legislation the Secretary of Agriculture is vested with authority beyond that originally granted by similar legislation. This aspect of the bill has been widely attacked, however, Mr. Walter G. Campbell, chief of the Food and Drugs Administration, points out that the charge is a fallacy, since the proposed law says "The findings of fact by the Secretary of Agriculture shall be conclusive if in accordance with the law."

In their attempt to attack the proposed legislation, "patent medicine" manufacturers particularly have insisted that it will prevent self medication. They have even insinuated that the Tugwell bill was prepared by the American Medical Association as a means of preventing the public from treating itself with household remedies as it has in the past. The insinuation is absolutely unwarranted. The American Medical Association has recognized the use of household remedies and has even listed in *Hygeia*, its magazine for the public, those which were considered particularly suitable for the family medicine chest. Secondly, as Mr. Campbell points out, the Tugwell bill recognizes the right of self medication but goes further in asserting that the person who does attempt to treat himself has a right to know what he is employing, its uses, and whether or not it possesses any dangers to his health. The manner in which this charge has been used by the "patent medicine" industry in attacking the Tugwell bill previous to any hearings might well be taken as a further indication of the real necessity for such legislation.

The Bureau of Legal Medicine and Legislation of the American Medical Association has been carefully analyzing the provisions of the Tugwell bill from the points of view of its protection of the public, its

adaptability to the practice of medicine, and its successful administration. No doubt the hearings that will be held on this bill before it comes up for final action before Congress will bring to light necessity for various modifications of its phraseology and even of some of its regulations. In the meantime, however, the American Medical Association goes on record as being wholly behind the principles represented by this legislation. The American people have a right to the greatest protection that the law can afford in relationship to their health. The use of foods, drugs and cosmetics is intimately bound with the health of the people. The evidence that the Food and Drugs Act of 1906 failed largely of its purpose because of gross abuses that developed in advertising is so glaring that it is common knowledge to the man in the street. The time has come for extension of this legislation to bring about better control. The leading associations in all the industries concerned recognize this necessity. Those manufacturers who exploit human frailty for personal gain are apparently girding themselves for battle, for they know that such legislation as is proposed means the death of their rackets. It will behoove the medical profession to be aware of the interests concerned and the principles involved, to follow the hearings on this vital subject, and to use all the influence it possesses to aid its passage, when a suitable bill is finally evolved from the proposed measure.

SOME FIGURES ON INDUSTRIAL ACCIDENTS

"Safety first" has become such a well known phrase that familiarity with it has tended to lessen the public sense of the significance of the campaign for accident prevention. One need only peruse the figures setting forth the heavy toll of life and limb that was exacted by many industries twenty-five years ago and compare them with those of the same industries today to be impressed by the remarkable progress that has been made.

The *Monthly Labor Review*, organ of the Bureau of Labor Statistics of the United States Department of Labor, published in its September issue an article on the accident experience in the iron and steel industry to the end of 1932.¹ Taking the industry as a whole, there has been a decline from 82.06 accidents resulting in death or disability per million man-hours worked in 1907 to 18.06 in 1932. In 1907, 69 hours of working time was being lost by injured workmen for every thousand man-hours worked. In 1932 the loss of time was 2.19 hours. This is a reduction of 68.3 per cent. The fatal accident rate diminished from 0.76 per cent in 1907 to 0.14 in 1932; permanent disability from 1.27 to 1.03; and temporary disability from 80.03 to 16.89.

These decreases have not been uniform in all branches and phases of the industry or in all states in which the

manufacture of iron and steel is an important enterprise. The best records are those of blast furnaces, Bessemer converters, plate mills, open hearth furnaces and rolling mills. The poorest are those of foundries, puddling mills, axle works and car wheels. In fact, the frequency rate in puddling mills increased from 47.07 in 1917 to 68.94 in 1932. Taking the four leading iron and steel manufacturing states, Pennsylvania, Ohio, Indiana and Illinois, Indiana has considerably the best record. In Indiana the rate was lowest in 1907, and the percentage of improvement was greater in 1932 than that of any of the other three states. Types of industrial processes and the emphasis placed on accident prevention are the most probable causes of these regional differences.

In the petroleum industry the last six years has witnessed a reduction in the accident frequency rate of 60 per cent and in the severity rate of 28 per cent. With an estimated cost to this industry of \$300 for each disabling accident, this reduction represents a saving of more than three million dollars in 1932. In the cement manufacturing industry the frequency rate fell from 10.61 in 1928 to 4.65 in 1932, and the severity rate from 3.72 to 1.80. Fifty-seven of 112 cement manufacturing establishments reported that they had had no disabling accidents in 1932, and thirty others had but one accident each.

The development of industrial safety codes which, since 1913, has been a function of the United States Bureau of Standards, has been transferred as a government economy measure to the American Standards Association. This association, organized in 1918 by five major engineering societies, is a federation of thirty-seven trade associations, technical societies and governmental departments.

LATHYRISM

Leguminous seeds, including edible beans, peas and the peanut, are such common ingredients of the diet in most parts of the world where these foods are freely available that few persons suspect the shortcomings of some of the species. In contrast with the cereal grains, the most common sources of human energy, with a protein content rarely exceeding 12 per cent, the legumes may be made up of as much as 23 per cent of albuminous constituents. As McLester¹ has pointed out, while the proteins of the legumes are of higher quality than those of the cereal grains, there is as a rule something lacking in their structure which limits their availability. Many of them are lacking in cystine. They have the power, however to supplement in a satisfactory manner the cereal proteins, this is particularly true of wheat and the pea and of wheat and the soy bean. The legumes are rich also in carbohydrate and contain a small amount of fat. The large amount of hemicellu-

Current Comment**INTRANASAL VERSUS INTRAPERITONEAL VIRULENCE**

The intraperitoneal virulence of the pneumococcus injected into mice is currently regarded as a reliable measure of its natural infectivity for this animal species. Such tests, however, may give a wholly misleading picture of its natural epidemiology. Webster and Clow¹ of the Rockefeller Institute report that, with the fifty pneumococcus strains thus far tested by them, intranasal virulence is in most cases wholly independent of the virulence as determined by the routine intraperitoneal method. High peritoneal pathogenicity, for example, is often accompanied by an almost total lack of nasal infectivity. There is a parallelism between nasal virulence and the tendency of the micro-organisms to set up carrier conditions and to spread by contact, but usually a complete lack of parallelism with virulence as determined by the routine intraperitoneal method. The New York investigators insist further that pneumococcus "stability" is widely different on the nasal surfaces and in internal tissues. Repeated intraperitoneal passage, for example, almost invariably enhances intraperitoneal virulence but has little or no effect on nasal pathogenicity. Repeated intranasal passage, in contrast, almost invariably causes a decrease and eventually complete loss of mucous membrane infectivity, which loss is not accompanied by a demonstrable reduction in peritoneal infectivity. If similar regional differences are found with *Bacillus tuberculosis* or with other microbe species, present-day epidemiologic concepts may require considerable modification.

SOME IMMEDIATE EFFECTS OF HEMORRHAGE

The ultimate effects of hemorrhage are familiar to physicians. Most conspicuous, perhaps, are the varying degrees of anemia, which may call for therapeutic or dietary prescriptions as well as time to complete the hematopoietic repair processes. Loss of corpuscles and their constituent hemoglobin cannot be recouped immediately. Adjustments of plasma volume occur much more promptly, so that persistent changes in vascular pressure may be averted in due season. Some of the physiologic responses to hemorrhage are, however, rapid. They may intervene in a period of a few minutes rather than hours or days. There is always some degree of fluid redistribution in the body. The details of this process have been studied by Adolph and his co-workers² at the University of Rochester. Immediately following, and even during, hemorrhage, distribution of the blood plasma is always observed. It is due to a rapid migration or transfer of fluid from extravascular spaces into the circulation. In the Rochester experiment the restorative possibilities of the spleen by means of its hidden resources of blood cells was excluded by preliminary removal of that organ. Some evidence of the source of part of the restorative fluid

lose in the bean often leads to intestinal fermentation and flatulence. The vitamin content of the legumes varies somewhat, they are as a rule lacking in vitamin A, all contain an abundance of vitamin B. They offer a good supply of iron and phosphorus but are usually deficient in calcium, sodium and chlorine.

There are, however, species of legumes that seem to be poisonous. The effect is designated as lathyrism, or vetch poisoning. Various writers allege that this has been known since the time of Hippocrates, that it has been common in the past in India and northern Africa, and that small local outbreaks have occurred frequently in Italy, France and elsewhere in southern Europe.³ For a long time it has been known that the disease is caused by the eating of lathyrus peas of three species, *Lathyrus sativus*, *Lathyrus cicera* and *Lathyrus clymenum*. After a poor crop of wheat, barley and other cereals, the poorer people in India and some parts of northern Africa are forced to eat the lathyrus peas as a large part of their diet, and lathyrism then becomes prevalent. The use of the peas as one third to one half of the diet for two or three months is considered enough to cause the disease.⁴ However, not all persons eating such a diet are affected, and in families only certain members are attacked. When the peas are eaten as a smaller proportion of the diet, they are said to be harmless.⁵ The symptoms in man are sudden and severe pain in the lumbar region, girdle sensation, motor paralysis of the extremities, tremor and fever.⁴

Opinions have differed with regard to the nature of the toxic agent in lathyrus seeds. The symptoms suggest the possibility of some degeneration of the spinal cord, and it has been proposed that this might be averted by appropriate dosage with vitamin A. An attempt has therefore been made at the University of Wisconsin⁵ to ascertain whether the abnormal condition produced by the peas was ameliorated or prevented by the feeding of cod liver oil or yeast as vitamin supplements. The species of lathyrus peas used was *Lathyrus odoratus*, the sweet pea used for ornamental purposes in this country. Lathyrism could readily be produced in experimental animals by feeding diets containing liberal amounts of the "sweet pea." Young animals received no protection against the toxicity of the sweet peas from cod liver oil or cod liver oil concentrate or from dried yeast, but the adult animals were protected to some extent by the inclusion of 2 per cent of cod liver oil in the ration. Cooking the sweet peas for two and one-half hours did not destroy their toxicity. The toxic factor was extractable from the peas by water at the boiling point. The protection against lathyrism lies in the avoidance of the dietary use of legumes of known toxicity.

² Adolph E. F., Gerbasi M. J. and Lepore M. J. The Rate of Entrance of Fluid into the Blood in Hemorrhage. *Am. J. Physiol.* 104: 502 (May) 1933.

was discovered by excluding certain viscera from the circulation. In their absence the rate of blood dilution was greatly diminished. There are observations to support the belief that even in man the immediate rate of entrance of fluid into the blood stream after hemorrhage may amount, for a time, to 0.25 cc per kilogram of body weight in a minute. Adolph has summarized the further immediate effects of hemorrhage as follows: the primary effects of loss of blood from circulation are to decrease the arterial, venous and capillary pressures and to decrease the rate of blood flow and oxygen flow to most tissues. To this situation the circulation responds by increase in heart rate, discharge of epinephrine, discharge of blood from the spleen, local vasoconstrictions, and local persisting ischemias. The respiration responds to the local asphyxia in its centers and to the pouring of lactate into the circulation by hyperventilation, followed eventually by asphyxia and cessation of breathing. In the capillaries, fluid flows into the blood from tissue spaces, water excretion by the kidneys is diminished, and various dissolved constituents interchange in response to the lowered pressures, to the anoxia, and to the altered types of tissue metabolism. This recital is indeed a thrilling picture of some of the factors that are brought into action when the integrity of the body functions is threatened.

Association News

ABSTRACT OF MINUTES OF MEETING OF BOARD OF TRUSTEES HELD AT ASSOCIATION HEADQUARTERS NOV 16 AND 17, 1933

A meeting of the Board of Trustees was held in Chicago on Thursday and Friday, November 16 and 17, 1933.

PROJECT OF ESTABLISHING MEMORIAL ROOM IN PERSHING HALL ABANDONED

Since, owing to the present economic conditions, it seems impossible to complete by popular subscription the fund of \$10,000 for the establishment in Pershing Hall of a memorial room in honor of the members of the medical corps of the expeditionary forces who served and gave their lives in the World War, it was decided to abandon the project and to return the money that has been collected.

HISTORY OF THE AMERICAN MEDICAL ASSOCIATION

A tentative outline for the preparation of a history of the American Medical Association as a symposium volume, was approved, and the editor was authorized to assign the chapters and to compile the material for the volume as rapidly as possible.

ASSOCIATION TO EXHIBIT AT FAIR NEXT YEAR

It was decided to continue the exhibit of the Association in the Hall of Science at the Fair in 1934 with the understanding that the standard of the medical exhibits be maintained as high for the next year as it was this year.

REPRESENTATIVES ON ADVISORY BOARD OF PUBLIC HEALTH AND CHILD WELFARE OF THE GEN- ERAL FEDERATION OF WOMEN'S CLUBS

Drs. N. B. Van Etten and A. C. Christie have been appointed to represent the American Medical Association on the Advisory Board on Public Health and Child Welfare of the General Federation of Women's Clubs.

PREVENTION OF PRENATAL SYPHILIS

With a view to carrying out the resolution adopted by the House of Delegates relative to the prevention of prenatal

syphilis a conference of representatives of the health agencies mentioned in the resolution was arranged, to be held during this meeting of the Board. After the conference, a committee was appointed to develop plans for disseminating information on this subject to the profession and to medical schools, using the facilities of the Association for this purpose.

CODIFYING OF DECISIONS OF JUDICIAL COUNCIL AND OF OTHER OFFICIAL BODIES OF ASSOCIATION

The Board authorized the codification of the decisions of the Judicial Council and of other official bodies of the Association.

DISMISSAL OF SUITS AGAINST ASSOCIATION

The Association's attorneys advised the Board of Trustees that suits instituted against the Association by P. L. Clark and the Ora Noid Company have been dismissed, on motions of the plaintiffs.

APPOINTMENT OF CHAIRMAN OF LOCAL COMMITTEE ON ARRANGEMENTS FOR CLEVELAND SESSION

By unanimous vote, the selection of Dr. C. W. Stone to act as chairman of the Local Committee on Arrangements for the Cleveland Session was confirmed.

PUBLICATION OF STUDY OF INSURANCE PLANS IN EUROPEAN COUNTRIES

Authorization was given for the publication in book form of a report from the Bureau of Medical Economics, based on a study of insurance plans in European countries.

MISCELLANEOUS

Other matters were given consideration, most of which will be taken up again at later meetings and reported on at some future date.

MEDICAL BROADCAST FOR THE WEEK

Talk over Network of the National Broadcasting Company

The American Medical Association broadcasts each Monday afternoon from 1:30 to 1:45, Eastern standard time (12:30, central standard time). The subject for Monday, December 11, is "Holiday Follies." The speaker will be Dr. W. W. Bauer, director, Bureau of Health and Public Instruction, American Medical Association. Subjects and speakers for subsequent broadcasts will be announced weekly in *THE JOURNAL*.

The following stations thus far have signified their intention of accepting the program: WEAJ, New York; WEEI, Boston; WTAG, Worcester, Mass.; WBEN, Buffalo; WFBR, Baltimore; WTAM, Cleveland; WWJ, Detroit; WSAI, Cincinnati; WDAF, Kansas City; and WMAQ, Chicago. Additional acceptances will be announced in *THE JOURNAL*, when received.

Radio Talks from Station WBBM

The American Medical Association broadcasts on Tuesday and Thursday mornings from 8:55 to 9 o'clock, central standard time, over Station WBBM (770 kilocycles, or 389.4 meters).

The subjects for the week are as follows:

December 12: Bunny's Revenge
December 14: Influenza

There is also a fifteen minute talk sponsored by the Association on Saturday morning from 9:45 to 10 o'clock over Station WBBM.

The subject for the week is as follows:

December 16: Do You Take Your Hearing for Granted?

THE CLEVELAND SESSION

Special Exhibit on Epidemic Encephalitis

The Committee on Scientific Exhibit has arranged for a special exhibit on epidemic encephalitis for the Cleveland Session, June 11-15, 1934. The exhibit will be in charge of the following committee:

Dr. R. C. Williams, United States Public Health Service, Washington, chairman.
Dr. James P. Leake, Washington.
Dr. R. S. Minkoff, St. Louis.

A competent corps of demonstrators will assist the committee and pamphlets on epidemic encephalitis will be distributed.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC.)

CALIFORNIA

Certain Eyelash Dyes Prohibited—All eyelash dyes containing aniline or coal tar products are prohibited from being offered for sale on the San Francisco market, by an order of the San Francisco Department of Public Health, effective November 15. Recent events, traceable to one product, have directed attention to the potential danger offered by the use of any of these preparations.

Annual Registration Due January 1—All practitioners of medicine and surgery holding licenses to practice in California are required by law to be registered annually on or before January 1, with the secretary-treasurer of the board of medical examiners, and at that time to pay a fee of \$1. Failure to pay the required fee within sixty days after January 1 works an ipso facto revocation of a license. Thereafter a license may be reissued only after application and the payment of a \$10 penalty.

Pediatric Meeting—The second annual meeting of the American Academy of Pediatrics (region IV) took place in Los Angeles, November 10-11. The guests of honor were Drs. Jay I. Durand, Seattle, and Clifford G. Grullee, Chicago. Physicians presented the following program:

Clarence M. Hyland: Tumors of the Kidney Region in Infancy and Childhood.
Madeleine A. Fallon: Iron Deficiency Anemias.
William M. Hays: Leukemia with Leukopenia.
Henry Dietrich: Tuberculosis in Childhood.
Howard R. Cooder: Cerebrospinal Syphilis in Childhood.
Howard T. West: Problems in Juvenile Diabetes.
Ezra S. Fish: Calcinoses.
Hugh B. Berkley: Congenital Idiopathic Edema (Milroy's Disease).
Victor E. Stork: Application of Psychiatric Social Work to Pediatric Practice.
Egbert Earl Moody: Postinfectious Encephalitis.
Philip E. Rothman: Observations on Therapy in Erysipelas.
Norman K. Nixon: Bacillary Dysentery in Children.
Mary F. Bigler: Serum Treatment in Sporadic Meningitis.
Oscar Reiss and Forrest N. Anderson: among others: Place of the Child Guidance Clinic in Pediatrics.

COLORADO

Hospital Meeting—The ninth annual meeting of the Colorado Hospital Association was held in the Cosmopolitan Hotel, Denver, November 15-16. Among others, the following speakers participated:

Dr. Isadore D. Bronfin: Denver, Protection of Employees in Tuberculosis Hospitals and Sanatoria.
Dr. Maurice H. Rees: Denver, Hospital Public Relations.
Mr. Walter G. Christie: Denver, Hospital Wage Standards and Vacation and Sick Leave Allowance.
Dr. Thomas Donald Cunningham: Denver, What Hospital Diets Should Contain.
Mr. Robert B. Witham: Denver, Hospital Social Service.
Mr. William S. McNary: Denver, Does Colorado Need Local Hospital Councils?

CONNECTICUT

Annual Registration Due During January—All practitioners of medicine and surgery holding licenses to practice in Connecticut are required by law to be registered during January, with the state department of health, and at that time to pay a fee of \$2. Licentiatees who have retired from active practice or who live out of the state must register annually but need not pay a fee. A practitioner failing to register is subject to a fine of not more than \$5.

Yale's Governing Board Reorganized—Announcement of the reorganization of the governing board of Yale University School of Medicine during the past year was made, November 20. The new arrangement places the responsibility more definitely and represents more adequately the many interests of the institution, it is believed. Two major sections of the board of permanent officers have been formed: the committee on the school of medicine and the committee on biologic sciences. The first deals primarily with problems of medical education and is subdivided into the committee on clinical subjects and the committee on preclinical subjects, while a prudential committee representing both of these subdivisions has been created to facilitate conduct of the regular business of the school. The committee on the biologic sciences deals with problems of

graduate education as distinct from medical education. As a standing committee of the school of medicine and the graduate school, it effects close cooperation between the two schools concerned with graduate work in the biologic sciences.

DELAWARE

Society News—Dr. Collier F. Martin, Philadelphia, spoke on "Proctology and the General Practitioner" before the New Castle County Medical Society, November 21.—Dr. Leonard D. Frescoln, Philadelphia, addressed the Delaware State Educational Association in Newark, November 10, on "Coupling Up Kinesiology with Prescribed Physical Exercises"—The Delaware Academy of Medicine, Wilmington, was addressed, November 2, by Drs. Frederic Maurice McPhedran and Esmond R. Long, Philadelphia, on "Pulmonary Tuberculosis in Children" and "The Nature and Significance of the Tuberculin Reaction," respectively.

FLORIDA

Annual Registration Due January 1—All practitioners of medicine and surgery holding licenses to practice in Florida are required by law to be registered annually on or before January 1 with the secretary of the state board of health, and at that time to pay a fee of \$1. A licentiate failing to register annually is subject to a fine of not more than \$50.

ILLINOIS

State Laboratory at University—A branch diagnostic laboratory has been established at the University of Illinois, Urbana, by the state department of public health, in response to a demand from physicians in the central eastern part of the state. The new branch, under the supervision of Fred W. Tanner, Ph.D., is prepared to do all diagnostic tests ordinarily performed in public health laboratories, including examinations for typhoid, undulant fever, tularemia, syphilis, malaria, tuberculosis, gonorrhea, Vincent's angina, diphtheria and rabies. Other diagnostic laboratories of the state department are located in the Capitol Building, Springfield, Southern Illinois State Normal University, Carbondale, and 1849 West Polk Street, Chicago. Specimens for the new branch should be addressed to the state diagnostic laboratory, room 360, Chemistry Building, Urbana.

Chicago

Society News—Dr. Isaac A. Abt delivered the presidential address before the Institute of Medicine of Chicago, December 5, on "Treatment of Whooping Cough: A Study in the History of Therapeutics"—At a meeting of the Chicago Society of Internal Medicine, November 27, Dr. Joseph L. Miller, among others, spoke on "Chronic Rheumatic Diseases of the Spine."—Dr. Agnes Beulah Cushman discussed "Pituitary Headaches" before the Chicago Council of Medical Women, December 1.—Speakers before the Chicago Surgical Society, December 1, included Drs. Alfred W. Adson and Winchell McK. Craig, Rochester, Minn., on "Diagnosis and Surgical Treatment of Spinal Cord Tumors" and "Surgery of the Sympathetic Nervous System," respectively.—The Chicago Laryngological and Otological Society was addressed, December 4, by Drs. Henry C. Sweeney on "Pathogenesis and Diagnosis of Bronchogenic Carcinoma" and Francis L. Lederer on "Pathogenesis and End Results of Sinus Thrombosis"—The Chicago Medical Society heard Dr. Lloyd D. Felton, Boston, speak on "Limitations of Serum Treatment," December 6, in a symposium on pneumonia. Drs. Frederick Tice and Charles Schott discussed the medical and pediatric aspects, respectively. At a dinner meeting, Dr. Felton reviewed the "History and Development of Serum Treatment of Pneumonia." A symposium on genito-urinary diseases from the viewpoint of the general practitioner will be presented before the society, December 13, by the faculty members of the University of Illinois College of Medicine.—Speakers before the Chicago Pathological Society, December 11, will include Drs. Theodore E. Walsh and William E. Adams on "Observations on the Cytology of Nasal Polyps" and "Vascular Changes in Chronic Experimental Atelectasis of the Lungs," respectively.

INDIANA

Aviators' Beacon on Hospital—An aviation beacon atop the Methodist Episcopal Hospital Indianapolis, was dedicated November 9. The light stands 250 feet above the ground and 80 feet above the roof of the building. Erection of the hospital beacon, believed to be the first in the United States, is said to have been suggested by one on St. Bartholomew's Hospital London, which has been burning since 1847, first an oil light

and now an electric signal Mrs Mary Hanson Carey, Indianapolis, donated the funds for the beacon The dedication program included as speakers Dr William N Wishard on "The Ideal of the Medical Profession in the Modern Hospital", Alden B Mills, Chicago, managing editor of *Modern Hospital*, N E Davis, secretary, board of hospitals and homes, Methodist Episcopal Church, Columbus, Ohio, and Robert Hahn, Evansville, president, Indiana Hospital Association The beacon will serve as a guide for aviators

IOWA

Outbreak of Typhoid—One death and twelve cases of typhoid were recently reported in Corydon, the most serious outbreak in Iowa this year, according to the state medical journal An investigation excluded the city water supply as the source of infection but revealed that nine of the patients used milk from the same dairy and two others lived on a farm adjacent to it The dairyman distributed raw milk, although caps on the bottles were labeled "grade A pasteurized" His wife gave a history of typhoid in childhood and an outbreak of the disease in 1918 was traced to the same dairy Although the woman is regarded as a typhoid carrier, several laboratory examinations at the time of the report failed to demonstrate a carrier state

Society News—Dr Frank H Lahey, Boston, will speak before the Linn County Medical Society, Cedar Rapids, December 21 on "Treatment of Thyroid Disease and Associated Conditions"—At a meeting of the Southeastern Iowa Medical Society, Dr John I Marker, Davenport, was elected president the principal speaker was Dr Edwin F Schneiders, Madison, Wis, on "Gynecologic and Obstetric Emergencies" Burlington was designated as the place for the next annual meeting in October, 1934—The program of an all day meeting of the Iowa Academy of Ophthalmology and Otolaryngology in Des Moines, December 5, was devoted to presentation of case histories with demonstrations—Dr Zella White Stewart, Iowa City, discussed allergy before the Des Moines District Dental Society, December 4 The Des Moines Academy of Medicine and Polk County Medical Society was invited to attend

LOUISIANA

Annual Renewal Due January 1—All practitioners of medicine and surgery holding certificates to practice medicine in Louisiana are required by law to renew those certificates annually on or before January 1, with the secretary-treasurer of the state board of medical examiners, and at that time to pay a fee of \$2 The board may by unanimous vote revoke any certificate not renewed

MAINE

Society News—Dr Douglas Quick, New York, addressed the Cumberland County Medical Society in Portland October 27, on "A General Survey of Cancer Therapy"—The Knox and Waldo county medical societies were the guests of the Kennebec County Medical Association in Waterville, October 19 speakers included Drs Ara B Libby, Gardiner, on undulant fever and Charles B Popplestone, Rockland, neurosyphilis—Dr Reginold Fitz, Boston, discussed "Auto-Endocrinology" before the Penobscot County Medical Association in Bangor, October 17—Speakers before the Somerset County Medical Association in Bingham, October 26 were Drs Eugene L Hutchins, North New Portland, and Edward E Bover, Waterville, on pneumonia and fractures, respectively—At a meeting of the York Medical Society in Sanford October 18 Dr Edward A Greco, Portland, discussed "Significance of Childhood Tuberculosis"

MICHIGAN

Annual Highland Park Clinic—The Highland Park Physicians' Club conducted its eighth annual clinic, December 6 with the presentation of the following program

- Dr Harry R Forster, Milwaukee Common Fungus Infections of the Skin Their Diagnosis and Treatment
 - Dr Thomas C Galloway, Evanston, Ill Surgical Diarrhea in Malignancy
 - Dr Carl A Hedblom, Chicago Thoracic Tumors
 - Dr Eric Paul Levi, St. Louis Renal Colic Without Pain
 - Dr John H Hill, Chicago Pathogenesis of Rheumatic Conditions A Medical Consideration of Focal Infection
 - Dr Frank Szedel, Louisville, Ky Obstetrical Deliveries
 - Dr Henry Germond, Springfield, Mass Venereal Diseases
 - Dr Robert Greenberg, Chicago Infectious Diseases and Skin Diseases
- Oration on "The Future of Medicine" by General L. H. H. H.

Erection of a Cancer Hospital Opposed—At a meeting November 1 the council of the Wayne County Medical Society voted to oppose on record any and all proposed erection

of a cancer hospital at Eloise The council believes that the new cancer hospital is not necessary, because less than 50 per cent of the hospital beds in the Detroit area are occupied and because all the private hospitals of Detroit have well equipped cancer services, and a sufficiently large number, the latest high voltage apparatus The society maintains that since the cancer services in Detroit hospitals are doing 75 per cent of their work on cancer patients free, it cannot justly be claimed that a special cancer hospital is necessary to take care of indigents, and, further, that statistics show that no better results are obtained in the special cancer hospital than in the private general hospital These objections with others formed the basis of the council's stand against the proposed construction

MINNESOTA

Annual Registration Due During January—All practitioners of medicine and surgery holding licenses to practice in Minnesota are required by law to be registered annually during January, with the secretary of the board of medical examiners, and at that time to pay a fee of \$2 A licensee who practices without renewing his license is guilty of a misdemeanor and is subject to prosecution

Layman's Health Audit Service Declared Unlawful—In a decision, November 3, the supreme court of Minnesota declared that the "health audit service," conducted by John Granger, a layman, furnishing urinalyses and blood pressure tests through the medium of a licensed physician doing the actual work was unlawful Granger sought an injunction in August, 1932, to restrain the state board of medical examiners from interfering with the conduct of this business Although a licensed physician did the actual work, Granger sometimes advised or passed on to the "subscriber" advice from the pathologist as to whether the results showed a normal or abnormal state of health and whether the "subscriber" should see a physician, in some cases advising as to diet, exercise and habits The court held that the plaintiff was engaged in the diagnosis or analysis of the condition of human health, which constituted a violation of the basic science law, and that advising the "subscriber" for a fee as to habits of diet, exercise or living, although not accompanied by any medical prescription or treatment, was a violation of the medical practice act

MISSOURI

New Officers for Clinical Society—Dr Rexford L Diveley has been elected president of the Kansas City Southwest Clinical Society, Dr Thomas G Orr, vice president, Dr Herbert S Valentine, treasurer, and Dr Hugh Wilkinson, secretary Dr Ira H Lockwood was named director of clinics, and Dr Edward H Skinner, editor of the society's *Monthly Bulletin*

Dr Goldstein Receives St. Louis Award—Dr Max A Goldstein, founder and director, Central Institute for the Deaf, St. Louis, was presented with the second annual St. Louis Award, November 4, "in recognition of his achievements and research in dealing with the problems of the deaf" The award, \$1000 in cash and a certificate, is made each year to "the resident of metropolitan St. Louis who contributed the most outstanding service to the development or performed such service as to bring honor to the community" The source of the award is a \$10000 fund, established anonymously by a St. Louisan Organizations of which Dr Goldstein has been president include the American Otological Society, 1927 American Laryngological, Rhinological and Otological Society, 1930, and the American Academy of Ophthalmology and Otolaryngology, 1902 He was recently awarded the gold medal of the American Laryngological, Rhinological and Otological Society for his work in the study and rehabilitation of the deaf child

NEW YORK

Annual Registration Due January 1—All practitioners of medicine and surgery in New York are required by law to apply annually, on or before January 1, to the secretary of the board of medical examiners for a certificate of registration on blank application forms to be furnished by him and to pay at such time a fee of \$2 The law authorizes the secretary of the board to permit secretaries of duly incorporated medical societies to act as his representatives to receive and transmit to him such application forms and fees Practitioners are subject to severe penalties for failing to register and for continuing in practice thereafter

Health at Utica—Telegraphic reports to the U S Department of Commerce from eighty five cities with a total population of 37 million for the week ended November 25 indicate

that the highest mortality rate (187) appeared for Utica and the rate for the group of cities as a whole was 115. The mortality rate for Utica for the corresponding week of 1932 was 112 and for the group of cities, 11. The annual rate for the eighty-five cities was 108 for the forty-seven weeks of 1933, as against a rate of 11 for the corresponding period of the previous year. Caution should be used in the interpretation of these weekly figures, as they fluctuate widely. The fact that some cities are hospital centers for large areas outside the city limits or that they have a large Negro population may tend to increase the death rate.

New York City

Third Harvey Lecture—Dr. Ross G. Harrison, Sterling professor of biology, Yale University School of Medicine, New Haven, will deliver the third Harvey Lecture of the season at the New York Academy of Medicine December 14. His subject will be "Heteroplastic Grafting in Embryology."

New Psychiatric Unit at Bellevue—Formal dedication ceremonies for the new Bellevue Psychiatric Hospital, First Avenue and Thirtieth Street, were held, November 2, at a meeting of the New York Society for Clinical Psychiatry in the auditorium of the institution. The hospital was opened last May with equipment for 375 patients, but its ultimate capacity will be 600. When completed, the eight-story building will give wide scope for modern methods of investigating mental disorders. Dr. Abraham A. Brill, president of the psychiatric society, presided at the meeting, at which speakers included James H. Fry, acting commissioner of hospitals, and Drs. George H. Kirby and Smith Ely Jelliffe.

Gifts to New York University—Chancellor Harry Woodburn Chase of New York University has recently announced the following gifts, among others, to the university since May for medical purposes:

Many donors through Mrs. Anne Tiffany for the Cardiac Clinic Endowment Fund \$22,750

Carnegie Foundation for the Advancement of Teaching for retiring allowances \$10,101

Anonymous donor for the Neurological Research Laboratory \$10,000

Carnegie Corporation of New York for the medical college \$8,750

Mead Johnson and Company for vitamin research \$2,000

Various donors for research in pneumonia \$1,400

Lederle Laboratories Inc., for experimental work on liver extract \$1,250

Lucius N. Littauer, \$1,000 for studies in prevention and cure of pneumonia

New York Foundation for research on infantile paralysis \$1,000

Hospital Deficits—Fifty of the fifty-six hospitals in the United Hospital Fund have reported an aggregate deficit of \$4,553,995 after applying their income from endowment on the year's expenses. These hospitals report operating expenses aggregating \$26,359,674 for the year, with operating income of only \$17,916,699. Income from endowment, which is less than usual, amounts to \$3,745,983, leaving a large deficit to be made up by public subscription, for which the fund is now making its annual appeal. Individual hospitals reported that returns from investments and private contributions have been greatly diminished, while persons who formerly would have been private or semiprivate patients are now using the wards or staying at home. Increase in free work and increased credit granted to patients have seriously embarrassed most of them. One hospital reported that its bills had not been paid for three months and employees had had to wait for their wages in November.

Society News—Drs. George A. Wyeth and Anthony Bassler addressed the New York Endocrinological Society, November 22, on "Embryology and Development of the Endocrine Glands" and "Internal Secretions of the Pancreas," respectively. A symposium on aniline tumors of the bladder was presented before the New York Society of the American Urological Association, November 23, by Drs. Russell S. Ferguson, George H. Gehrmann, Lang W. Anderson, Douglas M. Gay and Victor D. Washburn, Wilmington, Del.—Discussions of syphilis made up the program of the Medical Society of the County of New York, November 27, speakers were Jacob A. Goldberg, Ph.D., and Drs. George Miller MacKee, Abernathy Benson Cannon and Leon H. Cornwall.—The Association of Italian Physicians in collaboration with the Italian Historical Society held a commemorative meeting in honor of Bernardino Ramazzini at the New York Academy of Medicine, November 20, Dr. James J. Walsh spoke on "The Practical Genius of the Italians," Dr. James V. Ricci, "Origins of Italian Medicine," and Angelo M. Sala, "Bernardino Ramazzini, His Life and Works."—Dr. Jacob Earl Thomas, Philadelphia, addressed the Society for the Advancement of Gastro-Enterology, November 22, on "Pyloric Reflexes with Reference to the Regulation of Gastric Emptying."

NORTH CAROLINA

Society Presents Gold Headed Cane—The Davidson County Medical Society entertained Dr. Willis J. Vestal, Lexington, at a dinner, October 31, celebrating his fiftieth anniversary in the practice of medicine. Dr. Jarvis R. Terry, Lexington, was toastmaster. Speakers who paid tribute to the physician were Drs. Reno K. Farrington, Thomasville, Charles R. Sharpe, Lexington, Isaac H. Manning, Chapel Hill, John T. J. Battle, Greensboro, and John T. Burrus, High Point. Dr. Burrus presented him with a gold headed cane, the gift of the society.

NORTH DAKOTA

Annual Registration Due January 1—All practitioners of medicine and surgery holding licenses to practice in North Dakota are required by law to be registered annually on or before January 1, with the secretary-treasurer of the board of medical examiners, and at that time to pay a fee of \$5, if a resident of North Dakota, or \$2, if a nonresident. A practitioner may not practice if he has not registered. If he nevertheless continues in his practice his license may be revoked and can be reinstated thereafter on the payment of the delinquent fees and \$0.50 for each month of default.

OHIO

Hospital News—Dr. Norman F. Miller, professor of obstetrics and gynecology, University of Michigan Medical School, Ann Arbor, delivered the first of a series of clinical lectures to be given at Detwiler Memorial Hospital, Wauseon, November 23, on "Bleeding in the Last Trimester of Pregnancy." The lectures are sponsored by the Commonwealth Fund of New York.

Centennial of College of Medicine—The one hundredth anniversary of the founding of what is now the Ohio State University College of Medicine, Columbus, will be celebrated, March 3, 1934. Plans are under way for a reunion of graduates of the various schools which have been merged through the century to form the present medical school. A "One Hundred Year Book" will be published under the auspices of the faculty and the alumni committee, containing the history of the school and a record of the graduates. Subscriptions at \$10 are now being received by the sponsors. The college of medicine is the successor of five earlier schools, according to official records. The first was Willoughby Medical College, founded at Willoughby, March 3, 1834. Later it moved to Columbus and continued until 1848, when it became Starling Medical College. In 1892 Starling absorbed the Columbus Medical College founded in 1875, and in 1907 Starling merged with Ohio Medical University to form Starling-Ohio Medical College. The school was operated under that name until 1914, when the College of Medicine, Ohio State University, was founded and absorbed the property and the staff of the Starling-Ohio Medical College. Dr. John H. J. Upham is dean of the college of medicine.

PENNSYLVANIA

Hospital News—Montefiore Hospital, Pittsburgh, held its annual scientific day, November 25, with Dr. Leopold Lichtwitz, New York, as the guest of honor. Dr. Lichtwitz conducted a clinic on diseases of the kidneys, endocrine disease and diseases of metabolism and, following a dinner in the evening, delivered an address on "Angiospastic Diathesis."

Annual Registration Due January 1—All practitioners of medicine and surgery holding licenses to practice in Pennsylvania are required by law to register annually, on or before January 1, with the board of medical education and licensure in the department of public instruction and to pay a fee of \$1, or such fee as may be fixed by the department of public instruction. A practitioner who fails to register and who continues to practice is subject to a fine of from \$10 to \$100.

Dinner to Dr. Jackson—The Lackawanna County Medical Society gave a testimonial dinner, November 14, to Dr. Byron H. Jackson, Scranton, president of the Radiological Society of North America during the past year. Dr. Eugene L. Pendergrass, Philadelphia, was the principal speaker and Dr. William J. Corcoran, Old Forge, was toastmaster. Among the guests were Drs. George E. Pfahler, Henry K. Pancoast, William Edward Chamberlain, Nathaniel W. Winkelman and John T. Farrell Jr., Philadelphia. Francis Carter Wood, New York, John M. Keichline, Huntingdon, James John Quiney, Easton, and Sydney J. Hawley, Danville, A bound volume of precriptions expressing good wishes of his colleagues was presented to Dr. Jackson.

Philadelphia

Hospital News—Northwestern General Hospital has been taken over by Temple University Hospital and will operate as a separate unit in the university building

Mütter Lecture—Dr Arthur B. Duell, New York, delivered the annual Mütter Lecture of the College of Physicians of Philadelphia, December 6, on "The Pathology and Surgical Treatment of Facial Paralysis." At this meeting of the college, a portrait of the late Dr Hobart A. Hare was presented by Dr George E. de Schweinitz, on behalf of the artist and donor Mrs. James H. Hutchinson.

County Society Seminars—The second course of postgraduate seminars under the auspices of the Philadelphia County Medical Society concerns diabetes. Dr Edward S. Dillon delivered the first lecture, December 8, on medical and pathological aspects. Other speakers announced are:

Dr Eldridge L. Eliason, Surgical Aspect of Diabetes
Dr Ralph M. Tyson, Diabetes in Children
Dr Leonard C. Rowntree, A Consideration of the Ductless Glands
Dr Michael G. Wohl, Obesity
Dr W. Wayne Balcock, Thyroid Gland, Surgical Aspect
Dr John T. Farrell, Jr., Thyroid Gland, Influence of X Rays

At the final meeting of the series, Dr Moses Behrend will lead a round table discussion.

RHODE ISLAND

Society News—Dr Hiram Houston Merritt, Jr., Boston, delivered an address at the State Hospital for Mental Diseases, Howard, October 30, on "Diffused Sclerosis."—At the meeting of the Providence Medical Association, November 6, Dr Henry F. McCusker spoke on "Injuries to the Coccyx," and Drs. Reuben C. Bates, Stanley S. Freedman and William P. Buffum presented reports from the allergy clinic of the Rhode Island Hospital. Dr William N. Hughes addressed the association, December 6, on treatment of neurosyphilis, and Dr Paul Appleton presented a motion picture demonstration of congenital deformities.

TEXAS

Annual Registration Due January 1—All practitioners of medicine and surgery holding licenses to practice in Texas are required by law to be registered annually on or before January 1, with the state board of medical examiners, and at that time to pay a fee of \$2. If a practitioner fails to renew his registration within sixty days after January 1, his license is suspended.

Instruction in Malaria Microscopy—Baylor University School of Medicine, Dallas, will present its second malaria microscopy school, December 20-21, under the supervision of Drs. Walter H. Moursund, dean, Hardy A. Kemp, associate professor of bacteriology, John W. Brown, state health officer, Charles D. Reece, state epidemiologist, and Charles P. Coogle, microbiologist of the U. S. Public Health Service, and others.

Annual Public Health Meeting—Dr Thomas J. McCann, health officer of the city and county of El Paso, was elected president of the Texas Public Health Association at the annual meeting in Mineral Wells, November 10. Among the speakers were Dr. Horton R. Casparis, Nashville, Tenn., on prevention and control of tuberculosis, and Miss Jessamine Whitney, New York, on vital statistics in Texas. The next annual session will be held in Abilene.

GENERAL

Society Disbanded—At the recent meeting of the Central States Pediatric Society in Chicago in September it was voted to disband the organization. The annual meeting will be replaced by a regional meeting of the American Academy of Pediatrics. The society was seventeen years old.

Change in Status of Licensure—The Nevada State Board of Medical Examiners reports the following actions on licenses at a recent meeting:

Dr. Charles Mortimer Stewart, Los Angeles, license revoked on ground of unprofessional conduct.

Dr. Burton Willard Johnson, Ford, La., license revoked after investigation had convinced the board that it had been revoked without adequate cause. Dr. Johnson had been licensed in Nevada in 1909 and the license reached its term. The board reported that no record of any previous gain, loss, or other offense prior to the revocation and that the report of the action was sent to Dr. Johnson.

Results of Board Examination—Seventy-nine candidates were examined by the American Board of Otolaryngology in Boston, September 16, and their certificates distributed or failed. The board will hold an examination in Cleveland, June 11,

1934, during the meeting of the American Medical Association and another at Butte, Mont., in connection with the meeting of the Pacific Coast Oto-Ophthalmological Society early in the summer of 1934. The date for the latter has not been determined. Prospective applicants for certificates should address the secretary, Dr. William P. Wherry, 1500 Medical Arts Building, Omaha, for application blanks.

Orthodontists Deplore Misinformation Published—The American Society of Orthodontists at its last annual session adopted a resolution deploring misinformation and inaccurate advice in newspapers and other publications concerning malocclusion and associated deformities of the teeth. The advice given is frequently not in accord with the best practice and is also objectionable because, according to the resolution, it is impossible to make general statements of value on this subject owing to the fact that no two cases are alike. The society authorized the formation of a committee on public relations to cooperate with editors in preparation of accurate and useful information and to establish contacts with the public through the press, the radio and lectures before suitable groups.

Stolen—Anesthesia Research Apparatus—Dr. Paul M. Wood, 131 Riverside Drive, New York, reports that about \$1,500 worth of anesthesia apparatus and materials were stolen from his automobile, November 26. Much of the apparatus was especially built for research and is not of standard pattern. Every piece of metal was stamped with Dr. Wood's name or initial. Among the items taken were one gas-oxygen machine of the midget type Foregger make, special with seven jokes, two tanks of high pressure oxygen, one tank each of carbon dioxide, carbogen, nitrous oxide, ethylene and cyclopropane, several types of masks, two experimental fine control high pressure gas machines, several blood pressure outfits, five sets of spinal and regional anesthesia equipment with assorted needles, several laryngoscopes with tracheal catheters, one avertin outfit with avertin, and one resuscitation outfit. Money and other articles of value in the automobile were not touched. Dr. Wood would appreciate being notified at once should any physician be offered equipment bearing his name or scratched with the initial W. Reward is offered for any and all equipment recovered.

Tuberculosis in American Cities in 1932—The average death rate from tuberculosis in fifty-nine American cities with an approximate population of 33,000,000 was 56.3 per hundred thousand in 1932, as compared with 17.44 in 1910. Frederick L. Hoffman, consulting statistician, Newark, N. J., has recently made a detailed study of the mortality in 177 cities for 1931 and 1932. He found that in 115 cities the rate had decreased in 1932, in 60 it had increased and in 2 remained the same, as compared with rates for 1931. The five cities with the highest rates in 1932 were El Paso, Texas, 203.1, Little Rock, Ark., 154.4, Lexington, Ky., 154.3, Charleston, S. C., 151.3, and Augusta, Ga., 133.8. The report emphasizes two factors that complicate analysis of local tuberculosis mortality, namely, the racial factor and the concentration of tuberculous patients because of climatic advantages. The latter explains the high rate in El Paso and the former is also important because of the Mexican element in that city's population. These factors are also evidenced in reports of several states for 1932. New Mexico had the highest rate, 130.4, obviously because of the tuberculous concentration there and also because of the high death rate among the Indians. States with the next highest rates among the fifteen for which reports were available were Delaware, 62.9, Georgia, 61.7, Arkansas, 59.3, and New Jersey, 55. North Dakota had the lowest of the group, 24.4. Among the five largest American cities, Los Angeles had the highest rate, 77.1, and Chicago the lowest, 49.8. Here again the high rate in Los Angeles is attributed to the presence of numerous tuberculous patients and partly to the Mexican element. The lowest rates among the cities studied were Rockford, Ill., 10. Macellon, Ohio, 10, Grand Rapids, Mich., 10.8, Medford, Mass., 10.9, and Pontiac, Mich., 11.4.

CORRECTION

Medical Students in Rome—Figures received from the Regia Università di Roma (THE JOURNAL, August 26, p. 687, table 14) indicated that there were 132 American students enrolled during 1932-1933 and that 207 students completed the course. The figures being questionable, further investigation was made and it is now ascertained that the total number of students from the United States registered in the faculty of medicine was 188, the number who graduated during the summer session of the academic year 1932-1933, 7, and the number of students who applied for permission to take the final degree examination during the current fall session, 6.

Chronic Typhoid Carriers

The Medical Research Council has published a report on chronic typhoid carriers by Prof C A Browning, F.R.S. A temporary carrier state may follow an acute attack of typhoid, and it is difficult to assign a limit to the duration of the excretion of specific organisms. A large proportion cease to excrete within six months of convalescence, and thus appears to hold particularly for *Bacillus paratyphosus* A and B. The high incidence suggests the need of temporary precautions against the spread of infection during the convalescent as well as the acute phase. It is also important to remember that excretion in the feces, and especially in the urine, may set in several months after convalescence. It is agreed that those who continue to excrete bacilli after a year will not become cured spontaneously but become permanent carriers. These appear to amount to from 2 to 5 per cent of all cases of typhoid among British soldiers who have been invalided from abroad but when the disease is mild, as in England, the rate is probably lower. Chronic carriers may be fecal or urinary excretors. The fecal excretor may be a biliary carrier harboring the bacilli in the gallbladder, liver or bile ducts or a true intestinal carrier, in whom the bile is not infected, the bacilli persisting in the intestinal tract. The diagnosis of the latter depends on persistently positive cultures from the feces or intestinal contents and negative from the bile. It is not known whether the bacillus persists simply as one of the intestinal flora or whether the intestinal tissues are invaded. Chronic fecal carriers are usually married women, aged 34 and onward. There are four or five female carriers to one male. In the cases of biliary carriers it is important to know whether the bacilli persist exclusively in the gallbladder or infect the bile ducts and liver tissue. The association of gallstones with the carrier condition is well recognized. Chronic cholecystitis has been found in a large portion of the carriers operated on.

Urinary carriers are often found in the latter part of the pyrexial stage of the disease or early in convalescence. But only a small proportion become chronic carriers, and, unlike the biliary carriers, these are not preponderantly of one sex. This bacilluria is now held to be due to rupture of focal lesions into the renal tubules. If the bacilli persist in the urine, some pathologic condition of the urinary tract is the rule and the nidus is usually in the kidney or the pelvis. The bacilli may persist for years and cause extensive damage to the kidneys.

The chances of the spread of infection from patients suffering from typhoid have been greatly reduced by hygienic measures. In large cities the cases are mainly sporadic. They generally are attributed to a chronic carrier especially in rural areas, where they seem to be increasing in consequence of the tendency of city dwellers to make weekly excursions into the country. An important fact is that a carrier may transmit infection only at intervals, which may be separated by non-infective periods of years. But it seems unlikely, from the investigations of Browning and others, that the negative periods exceed more than six or twelve months.

Vaccination has not been found highly effective in preventing the persistence of organisms during convalescence but better results may be obtained from the potent strains now available. For the control of carriers, Browning thinks that there should be compulsory powers for examination of the blood, feces and urine. If a carrier is detected, his activities should be controlled and he should be prevented from handling food-

stuffs. In Scotland the local authorities have power to remove the carrier to a hospital or to isolate him. In England he can only be prevented from being employed in the preparation or sale of food. Cholecystectomy has proved successful in curing twenty-eight out of thirty-eight fecal carriers.

Progress in Radium Therapy

The Medical Research Council has issued a report summarizing the work of the research centers in 1932. Several of these indicate that skin tolerance—an important matter with the large quantities of radium now available—does not entirely depend on the time over which a dose is fractionated but varies with the region of the body and the blood supply. Thus the scalp seems to be about 50 per cent more tolerant than other parts of the skin. Regions with a depleted blood supply react less than normal areas, and the face is more tolerant than the neck. The advantage of spreading the dose over a long period is being more and more widely recognized. Hence at the Radium Institute many of the applicators of high content have been dismantled and smaller units have been constructed.

CANCER OF THE CERVIX

A modified technique has been adopted for cancer of the cervix with satisfactory results. Intra uterine and vaginal applications are still combined. By increasing the secondary screening of the vaginal applicators from 1 to 5 mm it has been found possible to increase the dose without exceeding the limits of tolerance. Vulcanite or bakelite is now used instead of para rubber. The applicators are spheroidal or cylindrical, with rounded ends so that the pressure on the vaginal walls is more even. It is hoped that this will obviate the severe immediate reaction and delayed radium necrosis that used to occur when there was not sufficient room in the fornices for lead tubes, which were then inserted. The activity of the applicators has been increased from 10 mg of radium to 15 millicuries of radon. The primary screening is 15 mm of platinum, as before. The applicators are inserted under general anesthesia and left for forty-eight hours, forty-eight hours later a vaginal application is made in the knee-chest position under the influence of scopolamine and pantopon. A week after this combined application, another is given. The radon will be replaced by radium when more radium is available. The new dosage has not caused any local damage.

Food Poisoning Due to a Carrier

Two boys, aged 11 and 13 years, died after eating peas pudding (*THE JOURNAL*, November 11, p 1572). Six persons in all were hospitalized suffering from severe abdominal pains after eating this pudding. At the inquest Mr F H Teale, lecturer in bacteriology at University College, London, stated that he examined the supply of split peas from which the pudding had been made and found them free from infective bacteria. He also examined some of the peas obtained from the bag in which they had been cooked. In these he found dysentery bacilli. In a sample of the pudding he found quite a large number of these bacilli. A little girl had taken some of the pudding from the crock in which it was kept, with her finger. Although she had no symptoms she was found to be infected with dysentery bacilli. She was therefore a carrier and seemed to have infected the pudding in taking it with her finger—an unusual cause of food poisoning.

Pay of the Defense Services Pronounced Inadequate

The government recently appointed a commission to examine the reasons for the shortage of officers in the medical branches of the defense services. This has presented a report that has proved unsatisfactory to the Naval and Military Committee of the British Medical Association. The committee has informed the military authorities that while agreeing that the medical

services should be reorganized to improve professional opportunity and add to economic advantages, it cannot approve of the proposed means. It regrets that the commission should have deemed it necessary to impose a condition, not within its terms of reference, that its recommendations should not involve any increase of expenditure. The main criticism is that the rates of pay and pensions are inadequate. The policy of the government has involved a reduction of pay, and the possibility of further reduction is a constant grievance to the serving officers and a strong deterrent to young physicians contemplating military service. It is urged that the minimum rate of pay should be that which existed before the 3 per cent reduction was made at the time of the national emergency. It is also urged that the short service system, advocated by the commission, would militate against efficiency.

Wood Sugar

Dr Bergius, the inventor of the Bergius process of hydrogenating tar and coal, and one of the chemists principally responsible for the production of synthetic foods in Germany during the war, spoke at the Institution of Chemical Engineers on recent developments in the production of foods by chemical processes in Germany. Sugar could now be produced from wood on a commercial basis. The raw sugar in its primary form can after neutralizing be used as a carbohydrate cattle food. Experiments have given good results, especially in fattening pigs. The nutritive value is practically the same as that of barley flour. In countries in which wood is obtainable in large quantities—the Baltic states, Rumania and the north-eastern part of the United States and Canada—wood sugar could be produced at a lower price than cane sugar in the tropics. In England, dextrose could be produced at an extremely low price from imported wood. The wood sugar represents not only a cattle food but a source for the production of yeast as well as dextrose for human consumption. For the overpopulated European countries wood may become an important factor toward independence of a food supply from abroad in the same way that coal hydrogenation will in some degree insure independence of a foreign oil supply.

Tribute to Prof Rutherford Morison

Rutherford Morison, emeritus professor of surgery in the College of Newcastle on Tyne, has reached his eightieth birthday. He has been one of the greatest and most original of surgical teachers. He is living in retirement on a farm in Scotland. On his birthday, a party of twelve of his old house surgeons unknown to him, made a pilgrimage to his house. He was asked to come into his dining room, where they had assembled. The *British Medical Journal* states that as he entered his face was a study—surprise, delight and other emotions swept across it and also affected his visitors. Each was greeted by name and the senior made a presentation of two armchairs. He mentioned the professor's valuable writings, the great and many kindnesses they had all received from him and his discovery of the happy treatment of septic war wounds. The professor was in excellent form and old jokes and old memories enlivened a meeting that will never be forgotten by those present.

Sir George Makins

Sir George Makins, consulting surgeon to St. Thomas's Hospital and past president of the Royal College of Surgeons, has died in his eightieth year. In the Great War he was senior consulting surgeon to the British Expeditionary Force. He turned his experiences to account in an excellent research on wounds of blood vessel. He wrote the articles on rickets, diseases due to microbial infection and parasites in *Treves, Syter et Surgery* and on thrombosis, embolism, phlebitis and surgical thrombosis in *Head's Dictionary of Surgery*. Among

the many professional bodies of which he was a member may be mentioned the American Surgical Association. Though his name is not identified with any special doctrine or discovery of a striking character, he stood in the first rank by reason of his knowledge, judgment and character. Quiet and unassuming, he was esteemed and loved as much as any man could be. It was plain to every one that he never acted from any but the highest motives.

Sir Arthur Keith's Successor

Dr John Beattie, associate professor of anatomy at McGill University, Montreal, has been appointed conservator of the museum and director of research at the Royal College of Surgeons, in succession to Sir Arthur Keith. Dr Beattie is a graduate of Belfast University, where he passed the examination for B.Sc. in 1920 with first class honors and obtained first place, and the M.D. examination in 1927, when he was awarded the gold medal. He was for a time research assistant and demonstrator in anatomy at University College, London.

The International Congress on Hygiene

The twentieth annual Congress on Hygiene was held in the Pasteur Institute, October 23. The minister of public health presided. The congress had an international character. The United States was represented by Dr Hugh S. Cumming. The scientific sessions, over which Dr Dequidt, head of the public health service, presided, devoted the whole time to discussion of two main topics: (1) the economic crisis and the great hygienic undertakings, and (2) coordination of the anti-tuberculosis crusade and urbanism. Dr Dequidt brought out in his inaugural address that the economic crisis compels one to view in a different light the sanitary undertakings in the various countries. Such undertakings are, however, about the most practicable that can be devised to give work to the unemployed. The expenditures are compensated for, to a great extent, by the money that is saved in the construction and support of hospitals and by a diminishing general mortality rate. Of the 14,000,000,000 francs (\$840,000,000) that the French government has decided to use for large undertakings of general value, it is to be hoped that a large sum will be devoted to such health promoting projects as improvements in the drinking water, sewage systems, and better housing facilities. Dr Rochaix, professor of hygiene at the Faculté de médecine de Lyon, and Mr Vignerot, chief engineer for rural hygiene, both stated that France was behind some other countries in these matters but that great efforts had been made in France in recent years. Mr Krul, director of the bureau of water supply in The Hague, pointed out that, in the Netherlands, the rural districts have today a much more abundant supply of drinking water but that great difficulties are encountered in supplying large centers of population, which are constantly growing. He suggested international collaboration in the use of the waters of the Rhine for the supplying of large cities. Dr Salmon recommended that groups of rural communes unite in the establishment of a water system for each group as is done in the region of Boulogne sur mer, with the government defraying a percentage of the cost. Mr Giberton described a highly sensitive method for discovering traces of hydrogen sulphide in drinking water suspected of pollution. Mr Fuss, head of the international bureau of labor of the League of Nations, advocated the use of the foregoing appropriations for the promotion of hygiene rather than for the increase of agricultural trial products which in all countries engenders misery as a result of overproduction. Vignerot emphasized the need of improving hygienic conditions in the rural sections which concerns in

France, 65 per cent of the population, and where child mortality is exceedingly high. Dr Barbary stressed the importance of soil pollution and the infection of fruits and vegetables consumed raw. Human excreta spread on fields from sewers is one of the most serious factors in the dissemination of typhoid and paratyphoid infections. He demanded that the spreading of sewage over agricultural fields be suppressed. Dr Iutrario, the delegate from Italy, described the progress that had been made in his country in supplying drinking water by means of aqueducts, wells, cisterns and the chlorination of river water. He referred to the aqueduct at Pouilles, a gigantic undertaking that supplies 260 inhabited centers, three entire provinces and parts of two other provinces serving thus a total of 2,600,000 persons. At present, 4,463 Italian communes are supplied through aqueducts with spring water. Mr Pittaluga, delegate from Spain, described the engineering feats accomplished to distribute the waters of the Ebro, Douro, Tagus, Guadiana, Guadalquivir, Segura and Jucar rivers. The French colonial ministry gave an account of what has been done to furnish drinking water for the inhabitants of overseas possessions.

On the second topic, "Organization of the Crusade Against Tuberculosis," there was not the same agreement. There was much discussion for and against the various systems proposed. Dr Chodsko, from Poland, emphasized that the crusade against tuberculosis should not be based on the same principles in the rural sections as in urban centers. He stressed as of primary importance the protection of children and the supplying of cities with sufficient food. In his opinion the tuberculous patient should not be separated from his family nor from his place of occupation longer than his condition permits, depending on the advice of his physician. He warned against tuberculous alcohol addicts, and particularly elderly tuberculous persons, who are frequently not sufficiently guarded against. Mr MacDougal described the success of the sanitary village of Preston Hall, in England, where the chief physician determines the periods of rest and work in the adjoining industrial establishments. Convalescent patients may live here at least five years and pay only a nominal rent. Not a single death from tuberculosis occurred among the children during the first year of life. Leclerc and Dujarric-de-la-Riviere said that there are not enough special hospitals for the treatment of tuberculous patients who will not be admitted to the sanatoriums, which makes it necessary to retain many contagious patients at home with their families. On no account should tuberculous persons be kept in a general hospital. There is a need they said of well organized medical centers where patients might be received who otherwise would wait long before securing a place in a sanatorium. Mr Armand-Dehille told of the excellent results of the Grancher society, which finds homes in the country for children of tuberculous persons; it has many chapters in nearly all the departments of France. The children who remain with their families present a morbidity of 60 per cent and a mortality of 40 per cent. Among the children cared for by the Grancher society the morbidity has dropped to 0.3 per cent and the mortality to 0.1 per cent. Mr Vitry advocated the early discovery of cases of tuberculosis among school children through the aid of the school physician. Mr Messerli, from Switzerland, discussed the crusade against tuberculosis in his country. The law of 1928 brought about greater uniformity in the cantons of Switzerland, which, until then, had their own particular organization. Mr Carrozzi, of the international bureau of labor, discussed the effects of work on the development of tuberculosis and stated that that influence is but slight as compared with other social causes. He advocated constant cooperation between the inspectors of labor with the dispensaries and the institutions carrying on the crusade against tuberculosis. Mr Jullien made some criticism on the

villages for the tuberculous, which are in reality, he said, only sanatoriums with separate pavilions. They are not practicable for persons of moderate income, or they require enormous subsidies. It would be better to favor the return of tuberculous persons to rural life and seek to improve, at the same time, the hygienic conditions in rural communities. Mr Jullien and Mr Sieur emphasized that for the examination of recruits about to enter the army radiology should be widely used, as is done in Switzerland.

International Congress on the Protection of Children

The *Congres international pour la protection de l'enfance* divided its work into nine sections. "Prenatal Consultations" was the subject of an excellent paper by Convelaire and Lacomme, who pointed out the service that such consultations render in the prophylaxis of dystocias and the detection of syphilis. The second section devoted itself to the training of mothers to aid in combating child mortality. The interest of young women in these questions should be awakened after they finish school. Alaria of Turin and Valagussa of Rome explained how such education is given in Italy. Mr Morquio of Montevideo stated that there has been a chair of puericulture in Uruguay for twenty years and that the results are excellent. Mr Klein of Prague called attention to the part played by the radio in giving such instruction. Several members described the efforts put forth by the private organizations of which they are the directors. The third section devoted to the second period of childhood, discussed the care of children aged 2 to 14. Many unofficial communications were offered on physical exercise, the value of playgrounds, periodic examinations with record cards kept up to date, breathing exercises, and even instruction in singing. The fourth section took up the supervision of the physical development of adolescents. In the fifth section, devoted to abnormal children, Dr Boncour explained the practical methods of teaching mentally abnormal children a trade. The sixth section recommended giving social aid to children of school age. The seventh section considered the organization of instruction for illegitimate children and expressed the desire that such instruction be provided in all countries. The two other sections dealt with the protection of native children in the French colonies, on which a considerable number of communications were presented. There was also a lecture by Mr Calmette on the use of the BCG vaccine against tuberculosis.

Federation of All 'Biologic Physicians'

Dr Wagner, federal director of the medical syndicates, has issued a proclamation to "all physicians of Germany who use biologic methods of treating disease." He points out that "the healing art comprises a much wider range and more methods than we physicians, as a rule, have learned. In spite of the advances of science, 'it must be admitted that therapeutic methods that are not in harmony with the regular school sometimes present results that are not only equal but occasionally even superior to those secured by the regular practitioner.' Although lacking the sanction of the profession, these methods have become an inherent possession of the whole population. Gradually groups of lay practitioners have been formed, and today one finds in Germany several societies employing similar methods. While special features separate them from one another they have the common purpose of furthering man's use of nature's remedies. Physicians who apply chiefly 'nature's remedies' are spoken of as 'outsiders.' It is planned now to combine the societies and leagues of the

latter into a federation uniting the so called biologic physicians of all cults. Only after such a union, it is explained, will it be possible to test these therapeutic methods and to give them the recognition they deserve and to make them available for the training and further development of all physicians. It has been found that there is too little solidarity among these physicians to expect them to exert any marked influence on the medical profession as a whole or on the scientific conceptions of medicine.

The Causes of Death for 1931

The federal bureau of health has published an analysis of the statistics on the causes of death in the German reich for 1931. With the exception of the years 1927 and 1929, the number of deaths has declined continuously since 1924. The year 1931 brought a slight upward trend which was, however, confined to the first quarter. According to the preliminary reports, the year 1932 brought a further decline. The rates for the years 1930-1932 (about 11 per thousand of population) are far below the proportion for the last prewar year (148 per thousand). In 1931 the most marked increase in any direction concerned influenza during the first quarter. The deaths from other infectious diseases showed a decline. That was particularly true of puerperal fever, scarlet fever, measles, rubella (German measles), diphtheria, pertussis, typhoid and erysipelas. The tuberculosis mortality remained essentially unchanged. The deaths from diseases of the circulatory organs and from apoplexy showed an increase. The constant increase in the number of deaths from cancer and other neoplasms was caused in part by the present unusually high representation of the older age groups and in part by more accurate determination of the causes of death. The cancer mortality of the year 1931 (122 per 10,000 of population) was the highest observed since 1924. The proportion for women was considerably higher than for men (131 as to 113).

Instruction in Heredity Made Compulsory in the Schools

A decree of the Prussian minister of public instruction concerning instruction in heredity and in ethnology in the schools went into effect, October 1. Until a final revision of the curriculum has been completed, it is decreed that in the graduating classes of all schools, the following subjects must be incorporated in the curriculum: science of heredity, ethnology, eugenics, family history and demographic science. The essential basis for such instruction will be biology, for which, according to the decree, an adequate time (from two to three hours a week), if necessary at the expense of mathematics and foreign languages, must be found. Since biologic thinking is to constitute the basis of instruction in all branches, likewise other subjects, such as German, history and geography, must be brought into the service of such instruction. In all final examinations, every pupil must be tested as to his knowledge of the new subjects and no person may be exempted from such tests. The minister will appoint commissioners to supervise the results of the examinations.

Prof. Werner Korte Honored

Prof. Werner Korte, who was for many years the surgical director of the Berlin Urban-Krankenhaus, celebrated his eightieth birthday, October 21. His father had occupied a leading position in the medical profession in Berlin and for that reason his son is still spoken of as 'der junge Korte.' Through his collaboration with Albert Fraenkel, internist of the hospital, he was able to bring about a wide development of surgery of the internal organs, so that he was counted among the most eminent surgeons in Germany. His books on surgery of the liver and of the pancreas are still regarded as classics. From 1899 on he was editor of *Deutsche Medizinische Wochenschrift*.

and of the *Deutsche Gesellschaft für Chirurgie* a post which he resigned only a few years ago.

Reorganization of Instruction in Hygiene

In institutions of higher learning an endeavor is being made to reorganize the instruction in hygiene. It is planned to make the instruction in ethnology and hereditary science of health a special branch of hygiene forming a part of general hygiene, whereas bacteriology is to be taught separately from hygiene. Ethnology and hereditary science of health are no longer to be regarded as auxiliary subjects of hygiene but will be given a standing consistent with their importance in that portion of the curriculum dealing with the care of public health.

Professor Duhrssen's Death

The death, in Berlin, of the gynecologist Prof. Alfred Duhrssen, at the age of 72, is announced. While serving as assistant of Gussersow, at the Charité-Frauenklinik, in Berlin, he devised Duhrssen's tampon for the prevention of fatal hemorrhage in childbirth. He became even more widely known in connection with his "vaginal cesarean section," which he first described nearly forty years ago. He introduced a number of other operations or improvements in well known methods. He worked indefatigably for reforms in obstetric practice.

ITALY

Oct. 1, 1933

Surgical Treatment of Duodenal Ulcer

Professor Cavina recently gave the Accademia medico-fisica of Florence a demonstration of the Judd operation for the treatment of duodenal ulcer. The operation consists in excision of the ulcer, together with a partial pylorotomy, which comprises the resection of the two anterior thirds of the sphincter. This operation eliminates two of the chief symptoms of duodenal ulcer, namely, stasis and gastric hyperacidity. The same purposes can be attained also by gastrojejunostomy, which, however, leaves the ulcer in situ and exposes the patient to the risk of jejunal ulcer. The Judd operation is indicated in young persons, provided the duodenum is sufficiently mobile and not too much distorted, and in recent ulcers of the stomach wall, anterior to the bulb. Such conditions of operability are found in about half the cases.

The results are fairly satisfactory. According to statistics of the Mayo Clinic (1930), in 464 interventions only two deaths occurred, and of 369 patients who could be followed up the results were satisfactory in 90 per cent.

In recent months the speaker operated on seven patients with duodenal ulcer, and in every case the immediate results were excellent. The only untoward symptom was a grave pulmonary complication. The postoperative period of observation has not been long, but the results thus far appear favorable. Postoperative examination of the gastric contents tends to show an effective reduction of acidity. Radiologically the evacuation of the opaque medium in the cases examined took place in normal time—in one case with precipitation.

Increase of Foreign Students in the Universities

According to a report of the Istituto centrale di statistica, the number of foreign students enrolled in the universities of Italy was 487 in 1913, 700 in 1921, 1922 and 2,287 in 1932-1933. There has been an increase of 470 per cent in about twenty years. The foreign students constitute 4.5 per cent of the entire student population of the Italian universities and the institutions of higher learning. Sixty-four per cent of the foreign students are enrolled in the faculties of medicine and surgery. The universities of Pavia (460) and of Rome (329) have the largest representation of foreign students. With

regard to nationality, the largest groups are from Russia, Poland and the Baltic states (540), Rumania (392), and the United States (365)

Biologic Study of Woman

In the Istituto biotipologico of Genoa, Prof. Nicola Pende and his associates are pursuing research on the somatic and functional differences between the Italian woman and the fundamental ethnic stocks from which she is sprung. The first results secured concern the Ligurian woman. In Liguria, at least five chief racial types can be distinguished. The differentiation is often difficult, owing to the numerous crossings that have occurred, but it is not impossible, says Pende, in 68 per cent of the cases. The five racial variants are the Mediterranean, the Alpine, the Nordic, the East Baltic and the Dniaric (or Adriatic) races. The Mediterranean, the Alpine and the Adriatic races are dark, the other two are blond. Studying the five races from the point of view of fecundity these workers found that the Italian woman of Mediterranean race (who is dark) occupies the first position and in 85 per cent of the cases presented hyperfecundity or normal fecundity. On the contrary, among the women of the blond races they found a high percentage of infecundity or low grade fecundity amounting to not less than 68 per cent among the women of Nordic type. The middle position characterized the women of Alpine type, who present 45 per cent of hypo-ovarian subjects with little or no fecundity and 55 per cent with normal ovarian activity and normal fecundity. Also from the point of view of organic and functional robustness the woman of Mediterranean race occupies the first position showing herself to be sthenic in 66 per cent of the cases and asthenic in 34 per cent. On the contrary, the women of blond type are robust and sthenic in about 35 per cent of the subjects.

In the Mediterranean type of woman and in the blond Nordic type the longilineal body form prevails, while in the Alpine and East Baltic types there is a preponderance of the brachymorphic form.

In the women of the Mediterranean type and of the blond Nordic type, the nervous system shows a predominance of the sympathetic system, in the women of Alpine and East Baltic types there is, however, a dominance of the vagus and of the parasympathetic system.

Was Semmelweis a Hungarian?

The Swabians, who were Saxons, at one time contested the Hungarian origin of Semmelweis, stating that he was of German nationality. In a recent address before a medical society Dr. Alois Konrad, a pupil of Semmelweis, presented arguments that left no doubt as to the Hungarian origin of Semmelweis. He stated that formerly the Viennese Germans forced Semmelweis on Hungarians but now acknowledge that he was a Hungarian. When the theories of Semmelweis were new and he was being attacked, he was called "the fool of Vienna." He obtained a lectureship only after his second application, and even then for a long time an attempt was made to suppress his name. Today, educated foreigners recognize his Hungarian nationality. The Austrian obstetrician Chrobak regarded him as the greatest son of Hungary. Wyder, professor of obstetrics at Zurich, Switzerland, wrote a treatise about "the great son of Hungary." Johannes Grosse of Dresden in his obstetric monograph, published in 1898 devoted a special chapter to proving that Semmelweis was of Hungarian origin. Many other references of a similar nature could be enumerated. Semmelweis was born in Buda, Hungary, and his brothers fought in the war against Austria in 1848-1849. With the

exception of three university years, Semmelweis was educated in Hungary. That a major part of his medical studies were made in Vienna can be attributed to the fact that at that time the great trio Rokitsansky, Skoda and Hebra were teaching there. Semmelweis returned to Hungary in 1850 and applied for a hospital position. The original letter is in the archives of the city of Budapest under the number 17551, 1850. He wrote "Though up to now I have exercised my medical knowledge in Vienna, henceforth I wish to settle as a practitioner in my fatherland, and especially in my birthplace." Eleven years later, in a letter addressed to the Hungarian Scientific Academy, he wrote "Fate brought on events in such a way that when I made the discovery in 1847 I was beyond the boundaries of my fatherland, serving as a physician to the Vienna obstetric clinic."

He wore the Magyar national dress at a time when not every Magyar dared to do so. He was one of the first to lecture in the Hungarian language when most professors used German. The fact that Semmelweis wrote his great treatise in German originated, he said, in his desire to write in the language of those who did not accept his doctrines and on whom he wanted to make an impression. However, the essential details of his doctrines were published in the Hungarian language in 1858 in the *Orvosi hetilap* under the title "The Prophylaxis of Puerperal Fever" and again in 1860 under the title "Difference of Opinions Between Myself and English Physicians in Regard to the Origin of Puerperal Fever." His book appeared in German in the year 1861. Thus nothing remains but his German sounding name and the circumstance that one of his ancestors lived in Germany. But it is certain that his parents lived and were born in Hungary. Now, after all this, if any one considers that Semmelweis was not a Hungarian it would be just as erroneous as to say that Aristotle was not a Greek because he was born in Macedonia and learned the Greek language later on or that Richard I was not an English monarch because he was a Plantagenet and therefore of French origin.

Semmelweis was a Hungarian, and posterity will ever know him as such.

Free Choice of Physician Under Health Insurance

The Hungarian Medical Association recently took the position that the principle of free choice of physician must be adopted by every sickness insurance society. This decision is apt to transform the whole of medical practice with the insurance corporations. This question was the subject of endless discussion in medical circles. Those who are employed at present by corporations with a more or less fixed salary are not anxious to change a sure income for a position which is to be created at a later date. Those without a fixed salary or position take the stand that medical practice is a free profession in which everybody should prosper according to his ability and knowledge. Thus the profession has split into two groups. Both agree that those already employed cannot, by any means, get in a worse position. The transition will be difficult but not impossible. It is an advantage to the Hungarian medical profession that there are already examples from which they may adopt what is good. Both parties agree to adopt the French system whereby members of the sickness societies contribute, to a certain extent, to the costs of the drugs used. From the German system they wish to copy the ambulatory system, that is to say, the erection of several district dispensaries in large cities, where physicians work in turn for three hours.

There are also many problems that concern memberships in the sickness societies. Owing to critical financial circumstances in Hungary the ministry of public welfare has liberalized the income limit and that will make it possible for three fourths of the population to have access to social insurance. The elastic income limit will give rise to frequent abuses and will

remove many better class families from the sphere of private practice

Another ticklish question is how to produce the increased funds needed for the salaries of the increased number of physicians. In view of the fact that the membership fee cannot be increased under present circumstances, the only solution is that the state must contribute more to the expense of the insurance societies. After lengthy consideration the government acceded to this solution of the problem, with the reservation that its contribution be merely temporary and last only until present circumstances improve, when both employers and employees can pay higher insurance premiums

Marriages

OSCAR NOEL MORISON Cedar Grove N. J., to Mrs Ruth Bryant Reid of Southern Pines, N. C., in Roanoke, Va., October 12

ZEKE CANDLER GAMMEL, Old Hickory, Tenn., to Miss Marion Houston Tanksley of Birmingham, Ala., November 4

ELMER A. LARSEN, Centerville, Iowa, to Miss Favre Mae Smith of Des Moines at Clinton, October 21

ARTHUR WESLEY KISTNER, Elkhart, Ind., to Miss Virginia Droz at Washington, Iowa September 2

FRANCIS DRING WETHERILL LUKENS to Miss Emma Martin George, both of Philadelphia, in October

SAMUEL MOIR RICKMAN, Louisville, Ky., to Miss Rosemary Leila Honiker of Decatur, September 3

EDWARD JOHN KLOESS, Belleville, Ill., to Mrs Beulah Scott Mason of Leadwood, Mo., October 9

PAUL E. SWANSON, Peoria, Ill., to Miss Elizabeth Christensen of Virginia, Minn., September 2

WILLIAM A. SANDES, Soldiers Grove, Wis., to Miss Eda Nederloe of Mount Sterling, July 10

GERSHON JOSEPH THOMPSON, Rochester, Minn., to Miss Myrnie Tews at Iowa City, July 16

PAUL T. OKLEFE, Waterloo, Iowa, to Miss Marian Brouillard of Charles City, October 11

HENRY HAMAN HAMILTON to Miss Frances Allen both of Cedar Rapids Iowa, in October

ANDREW LE ROY KARABIN, Chicago, to Miss Clare Hazinski of South Bend Ind., October 31

CHARLES C. RUSSELL to Miss Winnie Greeson, both of Chatsworth, Ga., September 24

DAVID PAUL LIEBERMAN to Miss Selma Kaufman, both of Elizabeth, N. J., November 12

LEONARD AVERY HALLOCK to Mrs Lettys Curtis Jackson both of New York, October 27

HAROLD V. HOITER Kansas City, Kan., to Miss Martha Louise Louder, November 3

ELMER E. KOTTKE to Miss Doris Mae Coover, both of Des Moines, Iowa September 29

WILLIAM GARIAND HECKS to Miss Lucia Bell Page, both of New York September 9

SOLOMON SCHWAGER to Miss Evelyn Johnson both of Pittsfield Mass. November 10

ROLAND I. SCHACHT, Racine Wis. to Miss Helen L. Allman of Marshfield June 29

ROCCO JOHN FAZIO to Miss Concetta Anna Vacca both of Chicago October 21

HERBERT E. KOEPKE to Miss Martha Porter both of Cadiz Ohio September 12

WILFRED I. RIVERS Eastover, S. C. to Miss Mildred Tilghman August 1

IRIDENRICK E. WEST to Miss Ruth Larimer, both of Topeka Kan. October 10

SIMON LOFF SINGER Richmond Hill N. Y. to Miss Hilda Lind July 1

DAVID H. LANDO to Miss Janet Cohen both of Milwaukee June 28

Deaths

Alexander Quackenboss, Boston, Harvard University Medical School, Boston, 1892, member of the Massachusetts Medical Society, at one time professor of ophthalmology at the Dartmouth Medical School, Hanover, N. H., and Williams professor of ophthalmology at his alma mater, served during the World War, formerly on the staffs of the Massachusetts Eye and Ear Infirmary, the Massachusetts General Hospital and the Infants Hospital, aged 67, died, October 27, of metastatic carcinoma

Samuel Brown Hays, Lakeland, Ky., Kentucky School of Medicine, Louisville, 1902, member of the Kentucky State Medical Association and the American Psychiatric Association, at one time assistant to the chair of eye, ear, nose and throat, University of Louisville School of Medicine, Louisville, served during the World War, formerly on the staff of the Central State Hospital, aged 54, died, November 14, in Cloverport, of heart disease

Eldridge Eakin Wolff Cambridge, Md., University of Maryland School of Medicine, Baltimore, 1899, past president of the Medical and Chirurgical Faculty of Maryland and the Dorchester County Medical Society, member of the state board of medical examiners, formerly health officer of Cambridge, on the staff of the Cambridge Hospital, aged 59 died, November 7, of chronic nephritis and valvular heart disease

Holton C. Curl Medical Director, Captain, U. S. Navy, New York, Drake University Medical Department, Des Moines, 1893, University of California Medical Department, 1897, fellow of the American College of Surgeons, entered the navy in 1898, served during the World War formerly assistant to chief of the Bureau of Medicine and Surgery, aged 61 died, November 9, of angina pectoris

Lee Collins Redmon Lexington, Ky., University of Louisville School of Medicine, 1907, fellow of the American College of Surgeons, past president and secretary of the Fayette County Medical Society, formerly medical director of the public schools in Lexington, on the staffs of St. Joseph's Hospital and the Good Samaritan Hospital, aged 48, died, October 27, of carcinoma

George Francis Kelleher Postville, Iowa, College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1911, past president of the Allamakee County Medical Society, aged 46, died, October 23 of injuries received when the automobile in which he was driving struck a monument

Patrick Henry Hourigan Buffalo, Niagara University Medical Department, Buffalo 1893, associate in hygiene and public health, University of Buffalo School of Medicine, aged 63, on the staff of the Millard Fillmore Hospital, where he died, November 7, of lobar pneumonia and agranulocytosis

George Childs Macdonald, San Francisco, L.R.C.P., Edinburgh, Scotland, 1883, M.R.C.S., England, 1884, Université libre de Bruxelles Faculté de médecine, 1886, F.R.C.S., Edinburgh Scotland, 1887 formerly on the staff of St. Mary's Hospital, aged 72, died October 13, of heart disease

John Bynum, Winston-Salem, N. C., University of the City of New York Medical Department New York 1892 member of the county board of health member of the Medical Society of the State of North Carolina, aged 73 died, November 2, in the Duke Hospital, Durham, of thrombosis

George Punshon Bawden, Moose Jaw, Sask. Canada Manitoba Medical College, Winnipeg 1906, fellow of the American College of Surgeons, aged 60, on the staffs of the Providence Hospital and the Moose Jaw General Hospital, where he died August 9, of coronary thrombosis

William Alvis Guthrie, Franklin, Ky. University of Tennessee Medical Department Nashville, 1889, member of the Kentucky State Medical Association medical superintendent and owner of the Southern Kentucky Sanatorium aged 69 died November 9 of cerebral hemorrhage

Herman Jeffery Lichte Philadelphia University of Pennsylvania School of Medicine Philadelphia 1930 aged 25 formerly an intern at the Hospital of the University of Pennsylvania where he died September 12, of mastoiditis and pneumococcal meningitis

Maurice Oberlin Putt, Oberlin Pa. University of Pennsylvania School of Medicine Philadelphia 1873 member of the Medical Society of the State of Pennsylvania aged 81 died September 29 in the Harrisburg (Pa.) Hospital of arteritis obliterans

John Raymond Nagle, Worland, Wyo., University of Nebraska College of Medicine Omaha, 1927, member of the Wyoming State Medical Society, county coroner, formerly member of the state board of health, aged 37, died, October 31, of pneumonia

Daniel Brewer, Fairbury Ill., Bennett College of Eclectic Medicine and Surgery, Chicago, 1876, Hahnemann Medical College and Hospital, Chicago, 1877 member of the Illinois State Medical Society, aged 90, died, November 1, as the result of a fall

Leon Watson, Broadway, N. C., North Carolina Medical College, Davidson, 1900 member of the Medical Society of the State of North Carolina bank president aged 55 died November 2, in the Lee County Hospital, Sanford, of cardiovascular disease

Patrick Joseph Paul Hamill, Jersey City, N. J., Columbia University College of Physicians and Surgeons, New York, 1904, member of the Medical Society of New Jersey, on the staff of St Francis Hospital, aged 52, died, November 2, of heart disease

Samuel Robert Herring, Warren, Ark., Tulane University of Louisiana Medical Department, New Orleans 1900 member of the Arkansas Medical Society, proprietor of a hospital bearing his name, aged 62, died, October 28 of cirrhosis of the liver

John Chivers Stafford Lappeus ♂ Binghamton, N. Y., University of Buffalo School of Medicine, 1904 fellow of the American College of Physicians, on the staff of the Binghamton City Hospital, aged 55 died, November 17, of acute nephritis

Gustav A. Kletzsch, Milwaukee Bellevue Hospital Medical College, New York, 1882 formerly professor of gynecology, Wisconsin College of Physicians and Surgeons, aged 76, died, November 9, in the Milwaukee Hospital, of pernicious anemia

James Henry Eddy, Lakewood Ill., College of Physicians and Surgeons of Chicago, 1889 formerly a member of the school board, aged 70, died, November 9 in the Shelby County Memorial Hospital, Shelbyville, of injuries received in a fall

Gaston Rene De Cotret, Montreal Que., Canada, School of Medicine and Surgery of Montreal, 1915 formerly professor of obstetrics, McGill University Faculty of Medicine, on the staff of the Hopital Ste Justine, aged 42, died, October 10

James Lawrence Halsey, Islip, N. Y., Bellevue Hospital Medical College New York 1888, member of the Medical Society of the State of New York past president of the Suffolk County Medical Society, aged 73, died November 15

Henry A. Dedman ♂ Canby, Ore., University of Oregon Medical School, Portland, 1896 mayor of Canby, formerly bank president and member of the school board, aged 68, died October 28, of embolism and arteriosclerosis

William A. Knowlton, Cleveland Charity Hospital Medical College, Cleveland, 1867, Civil War veteran, aged 94, died, November 10 in the Fair Oaks Villa Sanatorium, Cuyahoga Falls, Ohio as the result of a fractured hip

John Albert Burke, New York College of Physicians and Surgeons, Medical Department of Columbia College, New York 1878, aged 79, died, October 25, at his summer home in Pittsfield, Mass., of chronic myocarditis

Eugene Robert McMurray ♂ Bartow, Fla., Rush Medical College Chicago, 1897, formerly secretary of the Polk County Medical Society on the staff of the Bartow General Hospital aged 59, died, October 25, of endocarditis

Romulus Adams Foster, Washington, D. C. Columbian University Medical Department, Washington, 1874, member of the Medical Society of the District of Columbia, aged 81 died October 26 of cerebral embolism

Frank Martin Patton ♂ Elkhart, Ind. Rush Medical College, Chicago, 1922 on the staff of the Elkhart General Hospital, aged 37, died, October 27, in the Washington Boulevard Hospital, Chicago, of acute leukemia

John Wellington Felty ♂ Hartford, Conn., Jefferson Medical College of Philadelphia, 1884, fellow of the American College of Surgeons, surgeon to the Charter Oak Private Hospital, aged 73, died, October 15

George Powers Quinn, Erlanger, Ky., Chicago College of Medicine and Surgery, 1917, served during the World War aged 42, died, October 18, in St Elizabeths Hospital Covington, of pleurisy with effusion

Vernon Llewellyn Oler ♂ Calumet Mich., University of Maryland School of Medicine, Baltimore, 1911, served during the World War, aged 47, died suddenly, November 16 at his home in Laurium, of heart disease

Phineas Hillhouse Adams ♂ New York, Columbia University College of Physicians and Surgeons, New York 1909 on the staff of the Bellevue Hospital, aged 50, died, November 9 of cerebral arteriosclerosis

Charles Herman Armstrong, Preston Iowa, Bennett College of Eclectic Medicine and Surgery, Chicago, 1907, member of the Iowa State Medical Society, aged 53, died, November 11, of carcinoma of the throat

Claude A. Adams, Durham N. C., College of Physicians and Surgeons, Baltimore, 1892, member of the Medical Society of the State of North Carolina, aged 62, died November 8 of carcinoma of the pancreas

Edward Engleton Moore, Wilmette, Ill. Dartmouth Medical School, Hanover, N. H., 1884, aged 77, died, November 1, in the Kankakee (Ill.) State Hospital, of senile dementia and chronic myocarditis

Alphonso Holland Carvill, Somerville, Mass., Harvard University Medical School, Boston, 1869, for ten years member of the school committee, aged 90, died, November 3, of cerebral arteriosclerosis

Jacob Jacobson ♂ New York Universität Bern Medizinische Fakultät Bern, Switzerland, 1927 aged 39, died November 17 in the Mount Sinai Hospital of agranulocytosis and bronchopneumonia

Thomas Tyler Wheeler, Trussville, Ala., Chattanooga (Tenn.) Medical College 1900 aged 57, died, October 13 in the Norwood Hospital Birmingham, of a gangrenous gallbladder with stones

Mildred Jenks McKee ♂ Sturgis, Ky. Johns Hopkins University School of Medicine, Baltimore 1916 formerly a medical missionary in China aged 46 died, October 29, of brain tumor

William Worman Livingood, Robesonia Pa., University of Pennsylvania School of Medicine, Philadelphia, 1899 aged 57, died October 25 in the Reading (Pa.) Hospital of pneumonia

William Smith Philips, Belle Center Ohio Columbus Medical College 1882 formerly councilman mayor and member of the board of education aged 80, died October 26, of pneumonia

John A. Jackson, Ronceverte, W. Va., University of Louisville (Ky.) School of Medicine 1887, formerly mayor of Ronceverte, aged 72 died suddenly, October 26 of heart disease

Franklin J. Oshay, Ladd Ill. Rush Medical College Chicago 1889, aged 71 died September 26 in the East Moline State Hospital Moline of chronic nephritis and myocarditis

Benjamin W. S. Wiseman, Culver Ind., College of Physicians and Surgeons, Keokuk, Iowa 1880, for eight years postmaster, aged 81 died November 4, of cerebral hemorrhage

Edgar McCormick, Jackson Center Ohio Medical College of Ohio Cincinnati 1886 member of the Ohio State Medical Association, aged 67, died, November 5 of heart disease

Edward Lee Batts ♂ San Angelo Texas, University of Texas School of Medicine Galveston 1897 on the staff of St John's Hospital aged 61 died suddenly, November 1

Charles Edward Hall, Atlanta Ga. College of Physicians and Surgeons Medical Department of Columbia College, 1895 aged 68, died October 22, of carcinoma of the prostate

Clement O. Sullivan, Monce Ill. Chicago College of Medicine and Surgery, 1912 aged 47 died, October 26 of an overdose of morphine, presumably self administered

John Hardeman Heard, Macon, Ga., Jefferson Medical College of Philadelphia 1881 member of the county board of education, aged 78, died, November 3, of endocarditis

Cyril P. Kirley, Lowville N. Y. Kentucky School of Medicine, Louisville 1875 member of the Medical Society of the State of New York aged 80 died November 3

Edgar Dwight Hill ♂ Plymouth Mass. Medical School of Maine, Portland 1877, on the staff of the Jordan Hospital aged 78 died, November 4 of heart disease

Samuel James Marks ♂ Bordentown N. J. New York Homeopathic Medical College and Flower Hospital New York 1914 aged 43 died October 28

Patrick Joseph Clark, Secaucus, N. J., Atlantic Medical College, Baltimore 1909, aged 49 died July 11, in the Hudson County Hospital, of heart disease

John Emmans De Mund, Montclair, N. J. Albany (N. Y.) Medical College, 1890, aged 67 died November 11 of arteriosclerosis and hypertension

Bureau of Investigation

ANOTHER HAY FEVER TREATMENT

The "New Filtration Method" of Edwin S. Leach, M.D.

For the past six or seven years the Bureau of Investigation has been receiving requests from physicians and others regarding what is called the "New Filtration Method" in the treatment of hay fever and allied conditions, said to have been originated by a Dr. Edwin S. Leach of Junction City, Kan. As specimens of the inquiries received, the following are more or less typical:

I enclose a pamphlet gotten out by an osteopath in Billings. Will you kindly inform me what this Filtration Method for the treatment of hay fever is? —(From a Montana physician.)

Can you give me any information on the treatment of diseases of the air passages called the Filtration Method originated by Dr. E. S. Leach? Osteopaths are advertising this system of treatment as a positive cure for colds, hay fever, asthma, etc. —(From an Idaho physician.)

May I have information relative to the Leach Climes operated by Dr. Edwin S. Leach of Junction City, Kansas? The *Medical Herald and Physio-Therapist* of Kansas City, Mo., published an article relative to the Filtration Method for relief and cure of hay fever and asthmatic patients. The cure is guaranteed. —(From a Kansas physician.)

Will you please inform me whether or not Dr. E. S. Leach at Junction City, Kan., is a member in good standing of the A. M. A.? What is his medical status? —(From a Wisconsin physician.)

Being unable to find any information in the literature relative to the Climes [Leach] named in the enclosed brochures, will you kindly advise me of the status of the work as outlined therein? —(From a California physician.)

These are fairly typical of the inquiries that come in regarding the subject matter of this article. Dr. Edwin S. Leach of Junction City, Kan., according to the records of the American Medical Association, was born in 1867 and holds a diploma from the Ensworth Medical College, St. Joseph, Mo., issued in 1894. He was licensed in Missouri in the same year and in Kansas in 1916. He is reported to have taken the California examination in 1924, but failed. According to the medical directories, Dr. Leach was at Marshall, Mo., from 1900 until 1909. Then his name is not found in either the old Polk's Directories or in the American Medical Directory until 1914, when it appears in Junction City, Kan., where it has been from that time on.

Dr. Leach is not a member of his local medical society nor of course, of the American Medical Association. Incidentally, Dr. Leach has given as his excuse for not being a member of the American Medical Association the fact that Geary County, in which Junction City is located, has no county medical society. This is not correct. Geary County has a medical society, although it is true that it did not come into existence as an entity until August, 1932. However, before that society was created out of the eleven physicians (including Dr. Leach) who practice in Junction City, Kan., eight of them held membership in the Kansas State Medical Society and therefore, of course in the American Medical Association. Obviously, there is another explanation for the fact that Dr. Leach is not a member of his state or the national organization.

In 1926 Dr. Leach was putting out a sixteen page advertising booklet entitled *Facts New and Old Concerning Hay Fever and Rose Cold The New Method of Treatment Originated and Perfected by Edwin S. Leach, M.D. Rhinologist of Junction City, Kan.* The booklet was addressed to the public and was an elaborate puff for Dr. Leach's treatment which was described as the first and only real cure. The hay fever public was urged to lose no time in coming to Junction City for treatment as owing to the great demand for the treatment we will soon book up to the limit of our present facilities. With a letter sent out by Dr. Leach to a physician in 1926 there went a printed Report Blank asking certain questions regarding the proposed patient and on the reverse side of the blank the recipient was asked to fill in the names and addresses of at least five of your friends afflicted as you are that we may send to them our liberal offer until we have booked our full quota.

On Oct. 8, 1928 Dr. Leach submitted to THE JOURNAL an article entitled *Hay Fever Its Cause Pathology and Treat-*

William Anthony Dotson, Freeburn Pike Ky. Kentucky University Medical Department, Louisville, 1906, aged 55, was shot and killed October 29.

Andrew Francis Hoff, Casper, Wyo. Drake University Medical Department, Des Moines, Iowa, 1898, aged 74, died, November 3, of acute dysentery.

John Sinclair Leonhardt, Los Angeles, College of Physicians and Surgeons, Keokuk, 1879, aged 74, died September 6, of carcinoma of the bladder.

Leo Horatio Hall, Edes Falls, Maine, Long Island College Hospital, Brooklyn, 1885, aged 71, died, August 5, of gangrene of the right foot.

John W. Martin, Coldwater Mich. Bennett College of Eclectic Medicine and Surgery, Chicago, 1877, aged 80, died, November 18, of senility.

Charles Berrien Hall, Chicago, Hahnemann Medical College and Hospital, Chicago, 1886, aged 73, died, November 14, of chronic myocarditis.

John A. MacGregor, Kansas City, Kan. Trinity Medical College, Toronto, Ont., Canada, 1890, aged 70, died, October 2 of encephalitis.

Louis Martial Pelletier, Rigaud, Que., Canada, School of Medicine and Surgery of Montreal, 1889, aged 69, died suddenly, September 16.

William Henry Bryant, Louisville Ky. Leonard Medical School, Raleigh, N. C. 1905, aged 53, died, September 4, of coronary thrombosis.

Charles Sherman McCarty, Muscatine, Iowa. State University of Iowa College of Medicine Iowa City, 1888, aged 69, died, October 3.

Jessie B. Brown, McGregor, Texas, Tulane University of Louisiana Medical Department, New Orleans, 1896, aged 60, died November 2.

John Thomas Hamilton, Kansas City Mo., Missouri Medical College, St. Louis, 1882, aged 77, died, November 6, of heart disease.

Thomas Jefferson Carr, Coryton, Tenn. Tennessee Medical College, Knoxville, 1893, also a minister, aged 73, died, October 24.

Homer Corbett Edwards, Piedmont, Calif., University of Michigan Medical School, Ann Arbor, 1892, aged 64, died, August 25.

Marmora De Voe Moody, Seattle, Homeopathic Hospital College Cleveland, 1877, aged 85, died October 14, of lobar pneumonia.

Arlington R. Havens, Blackwell Okla., Barnes Medical College, St. Louis, 1901, aged 64, died, in October, of septicaemia.

Herschel Halleck Stoner, West Los Angeles, Calif. St. Joseph (Mo.) Medical College, 1885, aged 72, died September 25.

Ulysses Grant Mason, Chicago. Meharry Medical College, Nashville, Tenn., 1895, aged 60, died October 5, of coronary occlusion.

John H. G. Reed Epes, Ala. Louisville (Ky.) Medical College, 1890, aged 65, died September 16, of carcinoma of the liver.

Fred Albert Starbuck, Abilene Texas. Eclectic Medical University, Kansas City, Mo. 1902, aged 72, died, September 25.

John Timothy Connelly, Bayonne N. J. Harvey Medical College Chicago, 1898, police surgeon, aged 59, died October 31.

Thomas Henry Bier, Brantford Ont. Canada. University of Toronto Faculty of Medicine, 1896, aged 59, died August 19.

John Charles Calhoun, Pittsburgh Cleveland Medical College, 1897, aged 61, died October 30, of uremia and nephritis.

Theodore S. Jennings, Louisville Ky. Louisville (Ky.) Medical College, 1887, aged 83, died November 12, of nephritis.

Charles Sumner Kellogg, Glendale Calif. Eclectic Medical Institute Cincinnati, 1881, aged 74, died September 19.

George Douglas Pratt, Sequel Calif. California Medical College San Francisco, 1898, aged 57, died September 15.

Allan Gibson Guelph Ont. Canada. University of Toronto Faculty of Medicine, 1895, aged 65, died September 27.

Benjamin Sides Pennington, Mtadern Calif. Keokuk (Iowa) Medical College, 1891, aged 76, died October 2.

Harry Lee Randal, Philadelphia. Jefferson Medical College Philadelphia, 1901, aged 66, died September 25.

ment," and suggested to the editor that he was sure that the article would "prove a most interesting subject to your readers" because the "Filtration Method has awakened tremendous interest on the part of hundreds of nose and throat men of the country." The same article that Dr Leach submitted to THE JOURNAL for publication had already appeared in the July issue of the *Western Medical Review*, although this was not the basic reason for rejecting the manuscript. The same article appeared in the October, 1928, issue of the *Western Medical Times* and again in the May, 1929, issue of the *Medical Herald and Physio-Therapist*. What is essentially the same article rewritten appears in the *Eye Ear Nose and Throat Monthly* for June, 1933, under the title "The Basic Etiology of Hay Fever." These two articles seem to be the only contributions that Dr Leach has made to medical literature in his nearly forty years of practice.

What is the Leach "Filtration Method?" Apparently it is essentially a slogan used to persuade medical men that it is necessary for them to take a "course" of instruction from Dr Leach in order successfully to treat hay fever with a proprietary medicine that Dr Leach has devised, sold under the name of "Rhino-Form" ("Two ounce, double strength, \$2.00"). The medical profession for some years has been voluminously circularized by Dr Leach, urging them to attend his "Clinics." These "clinics" are given not only at Junction City, but apparently in various parts of the country from the middle west to the Pacific Coast. In the "come-on" material sent out by Dr Leach, he urges physicians, as a preliminary to taking the course, to purchase his stenographic notes, which are said to be a reprint of his "educational lectures." These are sold for \$2.50. The course itself seems to have varied in price from \$100 to \$50. The thesis developed by Dr Leach is, first, that the nose is a filter which, when normal, stops and holds all dust, pollen, etc., that may be drawn in through the breath. When, however, the nasal tissues are in a "wasted condition," the dust and pollen are "allowed to filter through into the blood stream due to this defect in the filter." Let Dr Leach describe it.

In the upper third of the nose in all hay fever there exists a hyperabundance of the glandular tissue which is the absorbing tissue of the body. Filtration Method of treatment destroys this excess of the glandular tissue and in the healing process it is replaced by more of the connective tissue which tightens these membranes to the extent they become impervious to this pollen dust as in the normal nose. A scar tissue? No we do not carry the effort that far.

What Dr Leach calls his "Stenographic Notes" of his "Educational Lectures" is a forty-two page printed pamphlet entitled "Nasal and Air Passage Pathology." In the preface to his lectures Dr Leach declares that hay fever is "just another very distressing complication of catarrhal rhinitis." In his first lecture he states that the subject of hay fever "has been shrouded with more mystery than perhaps almost any subject we could have selected," but that he feels that he is "able to draw aside the veil that has shrouded this affliction with mystery and reveal it as one of the most simple pathological conditions with which we have to deal."

Of the efficacy of his "Filtration Method of Treatment" Dr Leach is quite convinced. He declares that "where the patient has been afflicted for ten years or less and we receive their complete cooperation, we can expect to get 100 per cent cures and most of them in the first season." With hay fever cases of more than ten years' standing, even with the complete cooperation of the patient, one will only get about 75 per cent of cures in either the first or the second season. However, many of them "receive a cure during the third or fourth year." The "treatment" which constitutes what Dr Leach calls his Filtration Method is essentially that of first swabbing the nasal tissues with a 2 per cent solution of cocaine and then the application of "Rhino-Form Single Strength." The nose and throat are then sprayed with an oil spray. After from one to three days' treatment of this kind, "Rhino-Form Double Strength" is used. If this brings about a "profuse bloody discharge," this is said to indicate a mere "sloughing away of all superfluous tissue and is in no way indicating harm being done to the membranes." In fact, Dr Leach says that "blood streaked discharge is a most favorable indication."

In cases of bronchitis and asthma, Dr Leach has what he calls a "local iodine treatment of the air passages" in which

a solution of iodine, tincture of belladonna, tincture of benzoin in alcohol is vaporized and the vapor inhaled by the patient. Should the physician be called when the patient is in the midst of a violent asthmatic attack, Dr Leach recommends the use of "Asthmoysin," a proprietary product that the exploiters claim contains "suprarenal and pituitary hormones." In other words, it is essentially epinephrine, although Dr Leach declares that "the effect of one subcutaneous injection [of Asthmoysin] will last longer than any of the common remedies, such as adrenalin, morphine and atropin." In those cases of asthma that are complicated by sleeplessness, Dr Leach recommends the prescribing of "Pamodyne," a proprietary which THE JOURNAL has characterized as belonging to "irrational shot gun mixtures marketed with unwarranted claims."

The preparation used to destroy the excessive glandular tissue is "Rhino-Form." Just what Rhino-Form is, apparently no one but Dr Leach knows. In some of his mimeographed material he has vaguely and ambiguously described it as a "silver solution obtained by treating silver nitrate with an alkaline proteid." Because of inquiries received, Dr Leach was recently written to by the A M A Chemical Laboratory, inquiring whether Rhino-Form was or was not a secret formula, and asking, if it were not, whether Dr Leach cared to furnish an accurate definition of its composition, stating the amount of silver, ionic and non-ionic, as well as the amount of silver protein. This rather simple request, which could have been answered in a short paragraph, first brought a three and a-half page (single spaced) typewritten letter from Dr Leach, in which the Leach Clinics and the reasons for them were gone into in great minutiae. But no information was furnished on the subject of the Laboratory's inquiry!

Dr Leach did state that no effort had been made to commercialize Rhino-Form—this in spite of the fact that for some years both printed and mimeographed advertising material on Rhino-Form has been distributed to physicians. Nor, stated Dr Leach, had "a word or line" gone out "from the Clinics or from the Rhino-Form Company urging the profession to purchase Rhino-Form." Dr Leach then stated that he had found "high percentage of silver nitrate solutions" the most effective preparations for overcoming the "hyperabundance of glandular tissue," which, he holds, is the cause of absorptions of poisons which produce hay fever. He stated, however, that applying to the nasal mucosa silver nitrate solutions up to a strength of sixty grains to the ounce, the patients complained that the reaction was intolerable and worse than the disease—which seems reasonable—and there was always the possibility of sloughing and deep scarification. Therefore, continued Dr Leach.

Our next hope lay in the possibility of treating these very high percentage of Silver Nitrate solutions with the idea of materially modifying the powerful Nitrate Radical without destroying the potency of the silver. The result we named Rhino-Form a Silver Nitrate high percentage solution not a formulae [sic] or combination of other agents but modified to the degree it will not slough unduly severely, or injure normal healthy membranes yet of a germicidal power equal to the untreated solutions producing no reaction that could be complained of. Rhino-Form is what we call a fool proof solution that will do no harm no difference how carelessly it may be used.

It is evident that this statement gives no more information of value on the composition of Rhino-Form than have the ambiguous pronouncements in the doctor's other advertising material. Dr Leach was again written to and asked whether his failure to furnish the information asked for was an inadvertent omission or whether it is a fact that the product is secret in composition. This brought the reply from Dr Leach that "in my former letters my statement given of the contents of Rhino-Form has been highly satisfactory to all men who have profited greatly through attendance at our Clinics." No further light was thrown on the composition of Rhino-Form although Dr Leach did extend his remarks in this letter to the extent of two full pages of single-spaced typewriting, emphasizing his sincerity of purpose and the unselfish contributions of his time to further the interests of the medical profession.

Rhino-Form is not put out under Dr Leach's name, but by the Rhino-Form Company of Junction City, Kan. It appears, however, that the Rhino-Form Company is merely a trade style used by Dr E S Leach in the exploitation of his preparation. The A M A Chemical Laboratory recently analyzed Rhino-Form (Double Strength) and the chemists' report follows

LABORATORY REPORT

"One original specimen of 'Double Strength Rhino-Form' (Rhino-Form Company, Junction City, Kan.) was submitted to the A M A Chemical Laboratory for analysis at the request of the Bureau of Investigation. The container was an ordinary 2 oz bottle that carried a label on which was the following

A modified form of silver nitrate robbing nitrate of some of its drastic action without destroying its potency

Do not shake Use of the clear solution

'The bottle contained 59 cc (2 fluidounces) of an odorless liquid-solid system out of which the solid would settle if the bottle was allowed to stand a short time. The solid was brown, the liquid without the solid, colorless, and the suspension partook of the brownish hue of the solid

"Qualitative tests on the liquid indicated the presence of large quantities of silver and nitrate ions. The solid when treated with an excess of ammonia gave a yellow solution that gradually faded. Quantitative determinations were as follows

Specific gravity at 25 C.	1.062
Silver calculated to silver nitrate	71 per cent*

*The silver was determined by titrating a nitric acid solution of the original. It is questionable whether the insignificant amount of silver in the solid portion was measured by this reaction

"From the foregoing, it is concluded that Double Strength Rhino-Form consists essentially of a neutral solution of silver nitrate of approximately 7 per cent strength and a small amount of a silver-bearing solid, possibly a silver protein compound and possibly some silver oxide. According to the label, the solid is not for therapeutic purposes"

NUTRITIONAL STATUS OF THE MINNEAPOLIS SCHOOL CHILD

To the Editor—The question of malnutrition, undernourishment, rickets and other evidences of food deficiency has been under constant observation in Minneapolis, with reference to the child of school age, for nearly two years

In response to a questionnaire from the Surgeon General of the U S Public Health Service a report was made in March, 1932, following a survey made by sixty-four school nurses and eleven school physicians. The tabulation of this survey showed that the children attending the public schools of Minneapolis showed no increase in nutritional disturbances resulting from insufficient diet as compared with the previous two calendar years. A second survey was made in the school system through the agency of the school nurses in June, 1932. The result of this survey was similar to the one made in the early part of the year

Reports from schools where public relief families predominate tend to show that such families showed no material tendency to malnutrition. The children from such families actually presented a better appearance as evidenced by laundry and clothing repair, than was customary

The tabulation of the individual examinations of children, 32,000 conducted by the school physicians in the schools, during the school year September 10-2, to June 1933, shows that conditions indicating undernourishment had actually lessened as compared with the previous two school years. There was an actual reduction in the lack of general development and muscular tone, fewer defective tonsils and adenoids, less errors referable to the nervous system, a reduction of 50 per cent in poor posture, less indications of anemia and a lessened tendency to clonus

A review of the report of the Oral Hygiene Department for the same school year shows 70 per cent of the mouths examined needing no dental repair or treatment as compared with 31 per cent the previous year and 27 per cent the year preceding

All these figures indicate that Minneapolis children are not suffering from the effect of the economic change in home life. Pediatric wards of the Minneapolis General Hospital are unusually free from cases of malnutrition in young children. Rickets is almost unknown. There are and always have been cases of undernourishment in the child life of Minneapolis. The point at issue, however, is that this condition has not grown worse during the past three years of economic stress

F E HARRINGTON, M D, Minneapolis
Commissioner of Health, Director of School Hygiene

THE WHITE BLOOD CELL COUNT

To the Editor—I was much interested in the editorial "The White Blood Cell Count" in THE JOURNAL, October 14. It interested me very much because, as many as thirty-two years ago, when I was a house officer at the Boston Children's Hospital, I made white counts (which were then coming into vogue) on every child who came into the hospital. I did this over a period of a few months. These children had pneumonia, appendicitis, congenital dislocation of the hips, bow legs, hare-lips, cleft palates, and various other acute and developmental defects. Apart from the acute conditions, the white count varied from 6,000 and 7,000 to 30,000, and at that time, the increased leukocytosis was interpreted as due to absorption from digestion, because many of the counts were taken within an hour or two after a meal, so, it was felt at that time, and still is, that there is a wide variation, in normal children, of the white cell count, and that in cases other than acute conditions, it should not be taken too seriously. On the other hand, there was at the hospital at that time as chief surgeon a man who many times came to a decision to operate, in cases of acute appendicitis, when the white count went up 200

Therefore, I was interested in your editorial calling attention to the definite variation of the number of leukocytes under normal conditions, and without this knowledge, of course, no satisfactory judgment can be formed

JAMES WARREN SPYER, M D, Boston

"THE STORY OF CHILDBIRTH"

To the Editor—The review of "The Story of Childbirth" in THE JOURNAL, November 4, says "The usual indefensible statement is made that the United States is the worst place in the civilized world for a woman to have a baby, and—unfairly—the statistics of various countries, which, all serious students of the situation decide, are not comparable are repeated again in an attempt to prove it"

I challenge the writer of the review to find any such statement in the text coming from the author. There is to be sure, a quotation from one of the most distinguished and accomplished obstetricians in the country that closely parallels the statement credited to me. What I did say (p 218) was

The indictment has been made and often repeated in the medical and lay press that the maternal mortality in the United States is the highest in the civilized world and moreover that the rate has not been lowered since 1915 and not appreciably lowered for a much longer period of time. The White House Conference is not willing to go on record as confirming this statement but it does submit undeniable evidence that the maternal and infant mortality in the United States ranks high among the civilized nations of the world

This I believe is a fair statement of fact based on the most reliable statistics available in Washington at the time of writing. I am in full accord with the author of the review in rejecting the sensational writings in the lay and medical press when such writings overstress the facts. Our maternal mortality is relatively too high and we need the cooperation of the public in reducing it at least to the level of those nations such as Sweden that are making the best showing, and I have

faith that in another decade or two this will be accomplished. I fully appreciate that there are mighty forces at work for the betterment of obstetric practice in America. Improved educational facilities in our medical schools and training schools for nurses, the establishing of more and better maternity centers, maternity hospitals, prenatal and postpartum clinics and the educational facilities afforded child-bearing women are all factors that will inevitably result in the betterment of obstetric practice in America. When this comes about the United States will rank with the nations that are making the best showing in maternal mortality.

PAIMER FINDLEY, M.D., Omaha

MENINGOCOCCIC MENINGITIS IN EARLY INFANCY

To the Editor—In THE JOURNAL, September 2, page 795 Dr. J. M. Ravid of New York refers to cases of meningitis in the new-born and in early infancy. We are aware of these case reports and of others in the literature on meningitis in very young infants. In our article in THE JOURNAL, July 22, page 272, we reported the occurrence of a case of meningococcic septicemia with meningitis in an infant aged 22 days, with a diagnosis correctly made within twenty-four hours of onset, immediate, adequate serum therapy given by the most desired routes, and early recovery. Later on in the article we mentioned that our patient was "the youngest patient in whom the condition has been reported." Possibly this statement is ambiguous, but since our case report referred to early diagnosis, serum treatment and rapid recovery, we feel that our patient is the youngest on record. Although others are reported we have been unable either in English or in foreign literature to find reference to any patient younger than 22 days with complete recovery. All other cases except one have been fatal. In the latter a hydrocephalus developed, and we have been unable to find any reference to the future course of this case. Hydrocephalus developing, naturally, cannot be termed rapid recovery. We might mention also that morphologic, cultural, agglutinating and typing tests proved the cerebrospinal fluid organism to be a meningococcus of types 1 or 3.

EMERGENCY COMMITTEE IN AID OF DISPLACED FOREIGN PHYSICIANS

To the Editor—An unfortunate aspect of the present situation in Germany is that it has brought misfortune to many of her scholars. These include the physicians and surgeons in professional and in academic positions, who are being forced to leave the country and seem doomed to forfeit their carefully prepared careers and opportunity for carrying on research. To save their services for the common good, organizations in several countries of Europe are working to secure for them positions outside of Germany. A similar organization has been formed in this country, which will work in conjunction with those abroad. This committee is called the Emergency Committee in Aid of Displaced Foreign Physicians. Its form of organization and its methods are similar to those of the Emergency Committee in Aid of Displaced German Scholars, of which Dr. Livingston Farrand, president of Cornell University, is chairman. Its purpose is to facilitate the placement of a limited number of specially qualified foreign medical men in noncompetitive positions, so that they may continue to carry on their scientific work.

In view of the plight in which so many American physicians find themselves at present because of the economic depression the committee will not encourage immigration into the United

States of displaced foreign physicians for the purpose of engaging in medical practice. The committee will keep in mind the necessity of avoiding recommendations that might result in injury to American physicians or introduce competition with them. In instances in which a stipend may be provided through the agency of the committee, it will be stipulated that the position is for full time service. The committee will also maintain a central registry of refugee foreign physicians, including a record of their qualifications, from which institutions in this and other countries may obtain information concerning persons qualified for positions that cannot be filled locally.

The officers of the committee are Dr. Bernard Sachs, chairman, Dr. Edwin Beer, treasurer, and Dr. George Baehr, secretary. The executive committee includes Dr. Alexis Carrel, Dr. S. S. Goldwater, Dr. John A. Hartwell, Dr. Foster Kennedy, Dr. Emanuel Libman, Dr. William H. Park, Dr. David Riesman, Dr. J. Bentley Squier, Dr. I. S. Wechsler and Dr. Hugh H. Young.

All communications should be addressed to the Emergency Committee in Aid of Displaced Foreign Physicians, Room 1704, 2 West Forty-Fifth Street, New York City.

GEORGE BAEHR, M.D., Secretary

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be noticed. Every letter must contain the writer's name and address but these will be omitted on request.

RUPTURE OF AMNIOTIC SAC DURING LABOR—DRY LABOR

To the Editor—I am somewhat at sea regarding certain obstetric dictums related both by professors and in textbooks. One is the subject of dry labor. Until recently most obstetricians taught that the premature rupture of the amniotic sac was unfortunate as it caused a longer labor with increased maternal and fetal morbidity and mortality. Now many excellent obstetricians assert that the amniotic sac is not a dilator and one of them rupture the sac before the advent of or during labor in order to shorten labor. I have always felt that the spontaneous rupture of the bag of waters frequently but not always preceded a malposition of the head or a nonecephalic presentation. I should appreciate a clarification on this point. Kindly omit name.

M.D. New Jersey

ANSWER—As mentioned in the query, there has been a distinct reversal of opinion concerning the value of the bag of waters during labor. Until recent years nearly all obstetricians maintained that it was meddlesome and dangerous to rupture the membranes before the cervix was completely dilated, unless there was an excellent indication for carrying out this procedure. Today, even in such a conservative clinic as the Johns Hopkins labor is not infrequently begun by rupturing the membranes. Of course, this procedure should not become a routine one in all or in most cases of labor. In some clinics on the continent, however, nearly all patients have the bag of waters ruptured artificially early in labor but this type of intervention is to be strongly condemned. When induction of labor is necessary at, near or beyond term there is no more certain and safe method of doing this than by rupturing the membranes. However this is true only if the fetal head is engaged and the physician is scrupulously careful about asepsis and antisepsis. It is the unanimous opinion of all obstetricians who have had considerable experience with this procedure that labor is almost invariably shorter than in the cases in which labor is not started by rupturing the membranes or even when the membranes rupture spontaneously. There is apparently no harm to the mother or the baby if proper precautions are taken. However, unless there is an urgent reason, the procedure should not be carried out if the presenting part is floating, because of the risk of prolapse of the cord. It is possible for an unengaged head to change its position after artificial or spontaneous rupture of the bag of waters but if the head is engaged, and certainly if it is fixed in the pelvis, malposition of the head is a rarity.

Thus far the absence of the bag of waters during labor has not seemed to affect the new-born child. One of the chief arguments formerly presented for keeping the membranes intact

was that an intact bag of waters acted as the dilating wedge of the cervix and thereby spared the fetal head from excessive pressure against the cervical ring during each contraction. This argument, as far as we can tell is not valid. However, there is a possibility that absence of the membranes during labor may result in small hemorrhages in the baby's brain which are too small to produce symptoms and signs at birth or shortly afterward. It is possible that such tiny hemorrhages may produce disturbances later on, but thus far this has not been demonstrated. Another argument in favor of retaining intact membranes as long as possible was that the fetal head was not as smooth a dilator as the membranes and therefore it had a tendency to injure the cervix. However, postpartum examinations of the cervix fail to bear out this contention. The attitude at present, therefore, is that if an indication for inducing labor arises, and the fetal head is engaged there is no apparent harm in rupturing the membranes for this purpose.

BERCOVITZ PUPILLARY TEST FOR PREGNANCY

To the Editor—I have recently read an article on the so called Berco viz pupillary test for pregnancy. The method described consisted in mixing 5 drops of the mother's blood with 1 drop of 10 per cent sodium citrate and dropping this in the eye of the mother. A positive reaction was supposed to consist of a change in the size of the pupil while the other pupil remained normal in size. This article also stated that the test was almost 100 per cent efficient in diagnosing pregnancy and that a negative reaction gave a true indication of the absence of pregnancy in approximately 75 per cent of the cases. Is this test considered reliable? Since the technique is so simple it seems that if the results should prove accurate it would be a more widely known and used test. Please omit name and address.

MD Illinois

ANSWER—The Bercovitz pupillary reaction to detect early pregnancy is not reliable enough to be dependable in doubtful cases of pregnancy. In a series of 107 cases of proved pregnancy reported by King (*Am J Obst & Gynec* 25:99 [Jan] 1933), a positive result was obtained in 68 per cent, a doubtful response in 10 per cent and a negative result in 21 per cent. In 108 tests on nonpregnant individuals there were 4 false positive responses and 11 doubtful reactions. In a series of 90 cases reported by Gordon and Emmer (*Am J Obst & Gynec* 21:723 [May] 1931) there were 64 per cent positive reactions, 14 per cent doubtful and 21 per cent definitely negative reactions. All the nonpregnant women in this series gave negative reactions.

One of the disadvantages of this test is that although the test is simple, there is difficulty in reading the result. A great deal depends on the interpretation of the observer.

It must be remembered that this test was not offered by Bercovitz as an absolute means of differential diagnosis between pregnancy and other uterine conditions. The information afforded by a positive reaction is confirmatory evidence along with that obtained by physical examination. In Bercovitz's first series he reported that the reaction was present in 80 per cent of the pregnancies studies in one group and in 62 per cent of the pregnancies in a smaller group.

TOXIC THYROID WITH LOW BASAL METABOLIC RATE

To the Editor—Is it possible for an individual to be suffering from a toxic thyroid and still have a normal basal metabolism? A woman patient aged 37 married with two living children gave birth to a seven month lightly macerated still born infant about one year ago. During her last pregnancy she had a blood pressure of 210 systolic, 120 diastolic. Albumin was three plus. She weighed 140 pounds (72.6 kg). She complained of headache, spots before the eyes and pain in the epigastrium. One month after delivery the pressure dropped to 130 systolic, 90 diastolic and the urine showed only a trace of albumin. Since then she has had a gradual loss of weight to 112 pounds (51 kg). Menstruation has stopped. Her appetite is poor. She is nervous. The pulse rate ranges from 100 to 120. She vomits after meals. She has a choking sensation. She is troubled with hot flashes and perspires easily. Excitement causes hitches to appear on the chest, neck and face. There is a moderate exophthalmic expression of the eyes. The basal metabolism is plus 8. The white blood count is 9,000. There is no enlargement of the neck, no thyroid nodules are palpable and no thyroid enlargement is visible on roentgen examination. Although there is a history of tuberculosis in the family tuberculosis has been ruled out by roentgen examination. Other organic diseases have also been ruled out. The Wassermann reaction is negative. Repeated in a series of tests with high caloric feeding and iodine restriction gave no result. I would appreciate your suggestion. Kindly omit name.

MD Indiana

ANSWER—It is possible although unusual for a patient with a toxic thyroid to have a low or even a subnormal basal metabolic rate. This may be observed in hyperthyroidism under partial iodine control or in thyroid exophthalmic goiter which has a moderate exophthalmic and a low or normal basal metabolic rate.

Clinically but little difficulty is encountered in the interpretation of wide variations from accepted standards of the metabolic rate, however, the interpretation of lesser variations from the accepted normal, as frequently seen in chronic cardiovascular disease of thyroid origin, may present considerable difficulty and such variations must be interpreted individually. The normal for the individual may vary considerably from the average normal, and the variation in an individual case from a high to a low average normal, as may occasionally be induced by the administration of iodine in chronic low-grade hyperthyroidism may amount to as much as 25 per cent. This should particularly be taken into consideration in interpreting the metabolic rate of cardiac patients in whom the disease is conceivably due to thyroid intoxication. The cardiovascular phenomena frequently dominate the clinical manifestations of the latter group, whereas the usual clinical evidence of hyperthyroidism may be much less obvious. A drop of from 10 to 20 per cent in metabolic rate in a patient with heart disease while under iodine therapy may be taken as supporting but not demonstrating a diagnosis of thyrocardiac disease. Hypertension is frequently observed in chronic hyperthyroidism. Such patients present the usual manifestations associated with hypertension of whatever variety, and occasionally it may be difficult if not impossible to demonstrate a thyroid relationship.

In the instance cited, many of the conditions found suggest a chronic, low-grade hyperthyroidism. For the reasons stated, a single metabolic rate determination of ± 8 per cent should not be construed to exclude chronic, low-grade hyperthyroidism. While an unequivocal diagnosis of chronic hyperthyroidism cannot be made, this seems to be the most probable diagnosis. The fact that the thyroid is neither enlarged nor nodular does not preclude such a diagnosis. If such a diagnosis can be substantiated, thyroidectomy under iodine control in the hands of an expert surgeon trained in thyroid work would be proper treatment.

EPILEPSY

To the Editor—While a student in an engineering college fifteen years ago a man who was then 21 years old was taken with epileptic seizures. He had been in perfect health previously. The seizures came every few days and would come any time night or day. He was treated by rest and by bromides. He took 90 grains (6 Gm) of sodium bromide daily without avail. He was studied by some of the best neurologists in the country who could not find the cause. Syphilis was definitely excluded. He went through the usual round of tonsillectomy, circumcision and so on without help. After eight months he was operated on in Cincinnati by a former president of the American Medical Association Dr. C. A. L. Reed who stated that the attacks were due to autointoxication from ptosis of the colon. This operation did no good. Later he was treated in Chicago by a physician who injected the patient's blood into rabbits and then injected the rabbit blood serum into the patient. These treatments helped as the periods between attacks became six weeks and the attacks came only at night usually in groups of five or six. No medicines were taken by mouth after the operation. After two years without medicine the patient was again put on bromides 60 grains (4 Gm) daily and has had no attacks since. He returned to college was graduated and at present has a good position as an engineer. His work is quite strenuous because of long hours and the responsibility of his work. After he had been without attacks for two years he married and has three children, all apparently healthy. The amount of bromide was gradually cut down and at present he is taking 10 grains (0.65 Gm) of bromide a day and 1 grain (0.065 Gm) of phenobarbital a day. While he has had no major seizures for twelve years he does have particularly when tired occasional transient ringing of the ears lasting a few seconds. At such times his head may feel thick and he gets relief by going to bed for a few hours. This ringing in the ears was always the premonitory sign of his major attack. Please advise me as to the following: 1. Would it be safe to discontinue sedatives entirely? 2. Is the use of 10 grains of bromide and 1 or 15 grains of phenobarbital daily likely to do harm to the brain, kidneys or other organs? To date they have not affected him. 3. Is it likely that his children will be epileptic? There is no other case of this disease in his family. 4. For the past few years the patient has used alcoholic drinks moderately. Is this likely to bring back the attacks? Please omit name.

MD Michigan

ANSWER—1. In view of the fact that the patient is apparently still having minor seizures it seems unwise to discontinue the remedies altogether. The bromide probably can be gradually eliminated without harm but the phenobarbital should be continued. It is well to remember that phenobarbital should never be discontinued suddenly in cases of epilepsy as there is a liability to the occurrence of a series of seizures.

2. Not in this case.

3. No definite answer can be given. In the absence of a family predisposition and especially if the mother's family history is without epilepsy it is quite likely that there will be no epilepsy in the children.

4. The occurrence of epileptic seizures is a positive contraindication to the use of alcohol.

PREVENTION AND TREATMENT OF RENAL CALCULI

To the Editor—A well developed though rather obese man aged 50 is subject to frequent attacks of renal colic and gout. The patient may for weeks have the daily passage of numerous small calculi in the urine. An analysis shows that these calculi are composed of practically pure uric acid. His blood chemistry is normal except for a very high uric acid content just under 7 mg to 100 cc. Roentgen examination reveals that the right kidney is normal but that there is a bifid kidney pelvis and bifurcation of the ureter and considerable enlargement of the left kidney. There is however, no evidence of damage. Treatment during attacks of gout has included sodium salicylate, colchicine, salicylate, neocinchophen, intravenous injection of an ampule containing salicylate sodium iodide and colchicine, also cold wet dressings of saturated solution of magnesium sulphate locally, forced fluids, a purine free diet, and sedatives. Treatment during attacks of renal colic included the use of some urinary antiseptic, forced fluids, sedatives and hypnotics and the alkaloids of belladonna. Recently the patient has been taking piperazine with distilled water and a low purine and high vitamin diet. I should appreciate your advising me as to the following points: 1 Whether some forms of drinking water are harmful and predispose to the formation of urinary calculi and attacks of gout. In this district we have what is commonly known as "Flatbush" water. 2 Whether it is advisable to subject my patient to cystoscopy and irrigation of his left kidney pelvis every few months to prevent accumulation of urinary stones. 3 As to the effect of diet. 4 As to proper medication for the prevention and treatment of the gouty attacks and the formation of calculi. Please omit name.

MD New York

ANSWER—1 While there are some urologists who maintain that distilled water should be used instead of ordinary tap water, in actual practice there is little harm that can be attributed to drinking the latter.

2 Cystoscopy and pelvic irrigation as a preventive measure may appear on the surface to be a reasonable form of treatment, but in practice it is both painful and unproductive of the described results. Small stones may pass eventually of their own accord, while large ones cannot pass spontaneously or with mechanical aid aside from surgery.

3 and 4 Diet has not been proved to have much effect in cases of renal calculus. The restriction of purine rich food and alcoholics is the generally accepted procedure in cases of gout. For the relief of the acute attack of gout, one of the colchicum preparations and external heat should be tried. If no relief is obtained, one of the narcotics will be necessary.

DIFFERENTIAL DIAGNOSIS OF CHRONIC SINUSITIS

To the Editor—I should like to have a diagnosis and suggestions for treatment for the following condition. Nine years ago the patient had an infection of the right sinus and two years later the left side became infected (the antrums). He became quite deaf with continuous tinnitus. Three years ago he had windows cut in both sides which are still open. They still drain but the thick pus has cleared. There is still considerable clear mucous discharge. Every six days he has a slight chill with a rise in temperature of from one fifth to two fifths degree with a marked increase of the head noise and an increase of the mucous discharge. There is a dry stuffy feeling of the nasal mucous membrane the first twenty four hours which soon fades into the increased discharge. The noise gradually subsides until the sixth day until almost lost and then the chill and fever appear again. He has had several cultures made but never has had a definite diagnosis or the germ isolated. All manner of treatment has been tried but to no avail. The deafness has improved since the windows were made. The general health is normal. The past history is negative except for the usual contagious diseases.

MD California

ANSWER—At first blush, it would appear that all the symptoms described were due to the chronic sinus condition. Nevertheless, closer consideration of a history in which one of the most outspoken features is a regularly recurrent chill accompanied by a slight rise in temperature makes one feel that this would be an unusual and rare effect of chronic sinusitis. Certainly every attempt should be made to rule out all other causes of chronic fever. Chief among these would be malaria, especially if the patient lives in a malarial climate, undulant fever, tularemia, Hodgkin's disease, in which the fever known as the Pel-Ebstein type occasionally occurs, and also such conditions as perinephric and subdiaphragmatic abscesses, as well as pyelitis and pyelonephritis. In the absence of any of these, one could assume that the symptoms complained of were due to the disease in the sinuses. Careful roentgen examinations should be made. Iodized oil, particularly, could be instilled into the antrums, with subsequent roentgen examinations to determine the condition of the sinus mucosa. In the event that roentgenographic evidence supports the clinical condition found in the nose, and the diagnosis of chronic suppurative sinusitis is made, surgery of a more radical type than the patient has already had should be considered. As to the ear symptoms, any marked impairment of hearing, accompanied by head noises in an older man, is highly suggestive of auditory nerve involvement. The

increased difficulty in hearing that accompanies the flare up of the nasal condition is probably a superimposed tubal catarrh. If the nose improves, the latter condition should improve also. In any case, careful tests to determine the nature of the deafness should be undertaken, if only to get an accurate prognosis.

RECURRENT HERPES SIMPLEX

To the Editor—A farmer aged 26 has had fissures in the anterior third of his tongue for the past eighteen or twenty months. Vesicles appear over the sides and the anterior surface of the tongue followed by these fissures. The fissures are quite painful, especially when the patient eats. He drinks plenty of water. His tongue is not dry or rough. The blood urine and gastric analyses are normal. There are no rough edges on the teeth. His dentist checked up on his teeth. He has spent approximately four months with each of two eye, ear, nose and throat specialists. He has been to five or six other doctors and has been treated by me for over three months all to no avail. I have alkalinized him had him scrub his tongue with soap and toothbrush, follow with a boric acid and alcohol mouth wash and apply tincture of myrrh every other day. Although his tongue seems almost to clear up these new fissures break out again. Please omit name and address.

MD Wisconsin

ANSWER—Did the dental examination include roentgenograms of the teeth? If not, these should be made to detect any focal infection. The use of an alkaline wash to cleanse the mouth is all right, but this must be done gently, with no scrubbing. The patient should use magnesia magma morning and evening as a tooth wash, leaving it in the mouth after the evening cleansing. When the ulcers or fissures appear, each one should be touched with a 5 per cent solution of chromic acid or a crystal of silver nitrate. The diet should be bland, and the excessive use of fruit should be avoided. The combination of equal parts of magnesia magma and compound mixture of rhubarb and soda internally, just enough to cause mild loosening of the bowels, may be useful. The diagnosis is recurrent herpes simplex.

SALT INTAKE AND GASTRIC ACIDITY

To the Editor—1 In cases of restricted sodium chloride intake the normal osmotic pressure is preserved by decreased renal excretion of salt. Is there also a decrease of gastric acidity? 2 Would a diet containing 2 Gm of table salt daily increase the gastric secretion of hydrochloric acid? 3 Would large doses of sodium bicarbonate decrease the chloride ion in the blood and decrease the gastric secretion of hydrochloric acid as a defense measure to maintain the normal acid base equilibrium and combat an impending or actual alkalosis? 4 I understand that experimental removal of the normal alkaline intestinal secretions causes an increased gastric acidity probably to combat an acidosis from loss of alkali. I have read that large doses of alkali stimulate increased secretion of hydrochloric acid but the reverse seems more reasonable on the basis of maintaining the normal acid base equilibrium. Has this question been settled by experiments or clinical data? Please omit name.

MD Chicago

ANSWER—1 and 2 No. These answers are based chiefly on experimental observations. Eimer (*Deutsche med Wochenschr* 56 997 [June 13] 1930) found that the acidity curve showed an upper trend even if a salt-free diet was continued for months. The human organism adjusts itself, he states, to the decreased chloride supply by limiting sodium chloride secretion in the urine so that neither tissues nor fluids show a deficiency.

3 Yes, but the doses must be large. The dosage of sodium bicarbonate must exceed 3 Gm. per kilogram in dogs (Boyd, *T E Am J Physiol* 71 455 [Jan] 1925).

4 This question is one difficult to answer. Experimentally a hypersecretion is noted lasting several days following the period of heavy alkali administration, but large doses reduce gastric secretion both in quantity and in acidity. Boyd's work indicated that calcium carbonate increased the flow of gastric juice. Clinical impressions of stimulation of gastric secretion by alkalis are not verified at this time.

ACETYLENE POISONING OR HYDROGEN ARSENIDE (ARSENINE)

To the Editor—Three patients have been admitted to the hospital within the past month with symptoms of acute catarrhal jaundice, enlarged liver, malaise, anorexia and a severe jaundice, one having an icteric index of as high as 130. Each of the patients has a history of having worked with acetylene torches in tanks or closed rooms. Is there any relationship between the inhalation of this gas or the products of this gas and the jaundice? If the gas is responsible, how does it produce the effect? What is the pathology? Should this type of case be treated as any other catarrhal jaundice or is there a specific?

B W PATTON MD Baltimore

ANSWER—Acetylene, as such, is of a low order of toxicity. Impurities and products of incomplete combustion are responsible for the abnormal states usually attributed to acetylene.

Both hydrogen phosphide (phosphine) and hydrogen arsenide (arsine) may exist in acetylene

The disease state described in the query is fairly characteristic of poisoning by hydrogen arsenide. In the typical case may be found vomiting, edema of the face and particularly about the eyes, coryza, lassitude, pain in the region of the liver, albuminuria, hemoglobinuria and jaundice

Assuming that these three patients, in fact, are suffering from occupational diseases, arsenic poisoning is probable. This may be proved by the establishment of arsenic in quantities above normal in the urine, blood or hair of the patients or in the acetylene gases (preferably of the same lot of gas) when burned in small enclosed spaces. When proved, obviously the treatment indicated is that appropriate for arsenic poisoning and its sequelae

TREATMENT OF LATE HEREDITARY SYPHILIS

To the Editor—A patient of mine at the age of 20 was taken ill and his sickness was diagnosed as heredosyphilis. His blood test at that time gave a 2+ Wassermann reaction and for this he was under treatment for two years during which period twenty-four injections of neoarsphenamine and about 400 of mercury compounds were made. He felt fairly well for the next two or three years when again he was taken ill and his blood examined and found again with a plus reaction. At that time he came to me and I have administered to him in four years forty-eight injections of neoarsphenamine and 200 of bismuth compounds. During the treatment he gained weight and was feeling better just from the first injections. Two weeks ago he came to me and told me that for about one year after the treatment he was feeling fine but that for the past two months he has been losing weight, appetite and sleep. I took a specimen of blood and sent it for examination which yielded a 2+ reaction. Another examination gave the same answer. Will you kindly tell me whether sulpharsphenamine or sodium thiosulphate injections should do better in cases like this or what do you advise for treatment? Kindly omit name

MD New York

ANSWER—Cases of late inherited syphilis in which the Wassermann reaction is persistently positive require a spinal fluid examination. Such symptoms as loss of weight, appetite and sleep may be due to a variety of causes. The treatment that this patient has had has been more than adequate. Sulpharsphenamine presents no advantages over neoarsphenamine except that it can be used intramuscularly. Sodium thiosulphate is not a spirocheticidal drug. Although a few observers have reported reversal of the Wassermann reaction following its use, its value in the treatment of syphilis is questionable. It should be reserved primarily for cases intolerant to the arsenicals and for the treatment of postarsphenamine accidents. This patient probably would do fairly well on milder treatment: iodides by mouth, mercury by injection, with occasional courses of bismuth arsphenamine sulphate. If the spinal fluid is positive intravenous injections of actarson might be tried

MENTAL DEPRESSION AFTER COITUS AND BILATERAL VASECTOMY

To the Editor—A man aged 40 married has had severe mental depression and insomnia often lasting for a week or more following each act of coitus or nocturnal emission, no matter how infrequent those may be. Abstinence for several months has had no beneficial effect on him. He had masturbated considerably when a boy and has had premature ejaculations and nocturnal emissions for many years. He has never had a venereal disease. The only abnormality found on examination was a congested posterior urethra and verumontanum. Those have not improved greatly under local applications of silver nitrate solutions (10 to 20 per cent) or even fulguration. Sedatives had only a slight temporary influence. His prostatic and seminal fluids are normal. It is quite evident that loss of seminal fluid has a marked depressant effect on this patient. The man is highly intelligent and desires a bilateral vasectomy, assuming the consequences of a sterilization. Would such a procedure be of any benefit to the patient? What might be the remote effects of a double vasectomy on his (1) sexual power, (2) mentality? Kindly omit name

MD Ohio

ANSWER—This is not an unusual case. The congestion in the prostatic urethra is certainly sufficient to account for all the symptoms. Abstinence or infrequent coitus can only make matters worse. The same may be said about applications of strong silver nitrate or fulguration to the congested prostatic urethra. The patient should not indulge in the practice of withdrawal but in regular normal sexual intercourse whenever sexually excited. The non-indulgence in coitus when sexually excited will only increase the local congestion. The local treatment should consist in gentle prostatic massage and instillations of weak silver nitrate solution (from 1/1000 to 1/500) into the prostatic urethra with the Buzard sound stringe every five days.

There is no remote effect of double vasectomy either on the sexual power or on the mentality except a possible lack of excitement.

UNUSUAL MENSTRUAL INTERVAL

To the Editor—I have a patient aged 19 years quite healthy with no obvious abnormality either by history or physical examination save that her menstrual periods have always occurred regularly every nineteen days and last five days. The patient is anxious because of this frequency and the attendant inconvenience. Is it advisable to attempt to lengthen the cycle and what means would you suggest? Kindly omit name

MD Ohio

ANSWER—While the increased frequency of menstruation is a great inconvenience, it does not indicate any pathologic condition. In the human female, with possible rare exceptions, menstruation always depends on preceding ovulation, and in the present state of knowledge no way is known of bringing about regular prolongations of the intervals between ovulations and therefore between menstrual periods. It not infrequently happens that, after a temporary amenorrhea produced by radium or roentgen rays, the menses that follow the period of amenorrhea more nearly approach the usual twenty-eight day cycle. However, since this patient is only 19 years old such treatment, even if it were more certain in its action than it is, would still be out of the question. It may be that after a pregnancy or later in life the menstrual intervals will change and this is about the only encouragement that can be given the patient at the present time.

DERMATITIS FROM CARBON PAPER

To the Editor—A man aged 53 weighing 235 pounds (106 Kg.) a railroad switchman has handled carbon paper for the last three years in making out his records and during this time he has had considerable eczema on his hands. This began on the right thumb and index finger. When I first saw him June 11, 1933 the eczema was of a callus-like nature and would crack, itch and annoy him. The condition still exists and is involving both hands in spots. He has never had eczema on any other part of his body. The eczema is evidently due to carbon paper. The patient also has a cousin who has eczema on her hands whenever she uses carbon paper. I should like to know whether any other cases of this nature have been reported and also the chemical ingredient of the paper that produces it.

MD New York

ANSWER—Typewriter carbon paper, hectograph types of ink, and indelible pencil leads are fairly common sources of dermatitis. The callus formation mentioned in the query suggests mechanical rather than chemical irritation. Aniline dyes enter into the three products specified. Methyl violet is a widely used one. Skin sensitization is a possibility, and secondary entry of fungi often aggravates and perpetuates the initial chemical dermatitis.

GONORRHEA IN A SIX YEAR OLD BOY

To the Editor—Please outline for me the treatment of uncomplicated gonorrheal urethritis in a healthy 6 year old boy. At present there is a copious discharge and slight burning on urination, edema of the prepuce and redness about the meatus have practically subsided under hygienic treatment. What is the prognosis for cure? Please omit name

MD New York

ANSWER—Gonorrheal urethritis in a boy of 6 years should clear up without any local treatment, as boys of this age generally are not subjected to the influences of either alcohol or sexual excitement, the two things surest to prevent proper curative response. It tends under such circumstances to be a self-limited disease and young boys generally recover promptly without serious complications if no traumatic treatments are given. Aside from local heat for edema, precautions regarding conjunctival infection and ordinary hygiene such a child needs little if any treatment and the prognosis for complete cure is little less than 100 per cent.

SENILE ANGIOMA

To the Editor—I have a woman patient aged between 45 and 48 years who has a tremendous amount of small red elevated spots all over her body. It seems that they multiply gradually. She wants to get rid of some especially those on her arms, chest and upper part of her back. These spots are undoubtedly small hemangiomas. Would the application of the electric needle be of use in this case? Are there any ill after effects following the use of the needle? Kindly omit name

MD Connecticut

ANSWER—The correspondent is right in diagnosis and suggested treatment. The senile angioma is an innocent growth that seldom becomes large enough to be disfiguring. Electrolysis is good treatment for the growths and will do no harm either immediately or afterward. The needle should be pushed through the base of the growth and a moderate current applied for a few seconds, then a second application parallel to the first should be made until the whole base has been treated. Cruent punctures are said to favor scarring.

TOXIC EFFECTS OF PLANT JUICES IN EYE

To the Editor—Recently I was consulted by a patient who had been gathering wild flowers a few hours before I saw her. As she broke one of the stalks, some of the sap of the flower spurted into her eye. She experienced severe burning in the eye at once. When I examined her a few hours later there was a mild ciliary inflammation, the epithelium of the cornea was faintly stippled and the pupil was unaltered in size and responded to normal stimuli. There was no disturbance of the interior of the eye. The next day the stippling of the epithelium was coarser but of less extent. Recovery has been uneventful. The patient was not able to tell me what kind of flower she had gathered. What substance would be encountered in the juice of the plant like this which would produce such severe pain and mild destruction of the epithelium? What would you offer for treatment other than sedatives, local anesthesia and protection of the eyeball? Please omit name.

M D Indiana

ANSWER—Since it is not known from what plant the sap emanated, it of course not possible to say what specific toxin was contained in the juice. However, the toxic effect of many plant juices on the eye is well known varying from mild conjunctival irritation to intense conjunctival edema, superficial or deep keratitis, and even iritis. For a discussion of this the reader is referred to the article on Injuries to the Eye by Wagenmann, on page 1594 of the Graefe-Saemisch handbook, second edition 1913 volume 9. The treatment described in the inquiry is eminently proper.

NO GLANDS FOR FEMALE CHARM

To the Editor—I have run into an interesting question in connection with some efforts to adjust a problem in domestic psychology. The layman reads a good deal of stuff nowadays and gets ahead of us folks some times. I wonder if any of your staff would have any suggestion to offer. All of my study has failed to stir up a clue. The problem is that of a husband who complains that his wife lacks femininity, that she is too wooden and matter of fact and he wants to know if there is some glandular treatment possible that will give her that feminine charm that made Cleopatra and Anon de l'Enfer famous. This is to be distinguished from sexual ardor which this patient does not lack. The problem seems to be rather the lack of that quality which is the opposite of he-manness and of that quality which to my mind approaches the charm of children. Of course we classify it as a constitutional property whatever that means. But do we have any means of increasing it when it is deficient? Please omit name.

M D Nebraska

ANSWER—There is no glandular extract which could replace the inherited or acquired qualities of feminine charm. A grown woman who has not learned in girlhood to imitate some older woman with this secret or these manners is not likely to go to school to acquire them later in life. Still all things are possible to some women.

BLEEDING AFTER DEATH

To the Editor—In a court case the question has come up as to how long a man will bleed after death. In this instance the man was shot in the head with a shotgun the incident occurring during the summer months the man was then thrown from an automobile and when found there was a small pool of blood under the man. The question arose as to how long the man could have been riding dead but still bleeding.

M D Georgia

ANSWER—Active bleeding cannot continue after death because the heart has stopped. Blood still fluid may run out of torn vessels after death, if the conditions are favorable but for how long and to what extent cannot be stated because the conditions involved would vary greatly in different cases. In the case mentioned it says that there was a small pool of blood under the man. It may well be that this pool of blood was caused by the oozing of bloody serum or blood stained cerebrospinal fluid from the wounds in the head. In any case, if the man was dead when thrown out, the "pool of blood" was not due to actual hemorrhage. In cases of hemophilia oozing or bleeding may continue longer.

ECZEMA OF AUDITORY CANAL

To the Editor—I have a case of moist weeping eczema of the ear canal in a dentist. I have used 10 per cent silver nitrate have kept water out of it and also used 5 per cent menthol and liquid petrolatum. Since the treatment has not helped I should like to have you suggest one. The patient is in perfect health. At times when the feet become hot in summer small edematous patches appear on them. Please omit name.

M D Ohio

ANSWER—In cases of eczema of the external auditory canal when simple measures such as have already been applied do not give the desired result, it is sometimes desirable to consult a dermatologist. In some of these instances the application of x-rays in certain definite doses is beneficial. In some cases this condition may be an evidence of allergy and the tests for protein sensitization should be made.

Colorado October Report

Dr William Whitridge Williams secretary Colorado State Board of Medical Examiners reports the written examination held in Denver Oct 3 1933. The examination covered 8 subjects and included 80 questions. An average of 75 per cent was required to pass. Two candidates were examined both of whom passed. Five physicians were licensed by endorsement. The following colleges were represented

Book Notices

Migraine: Diagnosis and Treatment By Ray M Balyeat M A M D, F.A.C.P. Associate Professor of Medicine and Lecturer on Diseases Due to Allergy University of Oklahoma Medical School. Cloth Price \$3 Pp 242 with 26 illustrations Philadelphia & London J B Lippincott Company 1933

The author bases his observations on about 350 cases seen during the last four years in which a diagnosis of migraine was made, he reports sixty-five cases in detail as typical of headache due to allergy. He emphasizes that "migraine refers to paroxysmal attacks of hemicrania (occasionally bilateral headache) associated with sensory and motor disturbances," the latter indicating disturbance of the cerebral cortex. He also points out that headaches without cortical symptoms may also be allergic or may be nonallergic, neither of these belongs in the migraine group. Typical migraine he regards as allergic, stress and strain are to be considered secondary factors just as change of weather must be considered a secondary factor in initiating an attack of bronchial asthma. The chapters on the history, heredity and physiopathologic mechanism of migraine are excellent. Emphasis is laid, with good reason, on the theory that symptoms are due to localized edema in the pia or cortex of the brain or in both, thus explaining the multiple and temporary symptoms of cortical irritation. The edema is probably due to increased capillary permeability in these localized areas and this, in turn, to hypersensitivity (allergy) to one or more foods. In other words, the mechanism of the edema of the brain is probably similar to that which is believed to occur in urticaria, hay fever, bronchial asthma and the other allergic diseases.

Issue can be taken with the author on the following points: 1 His description of migraine in children is vague and leads to doubt as to the correct diagnosis, fever and vomiting, without headache, are the symptoms reported. Even the fact that later on in life typical migraine occurs in these individuals does not prove at all that the childhood attacks were true migraine. In the absence of headache there would seem to be no basis for diagnosing migraine. Patients such as these probably account for the high percentage of cases in children quoted by the author, who states that 2 per cent of all children have migraine before the age of 10. This figure seems high in the experience of other men who have studied migraine. 2 The author contradicts himself on the results of his skin tests, on one page he obtains only 10 per cent negative tests, on another 30 per cent. In any case other men who have made skin tests of patients with migraine have not been able to obtain anywhere near such a high percentage of positive skin tests. 3 His results of treatment, as quoted are also better than those obtained by most other allergists. The figures given are excellent (from 80 to 100 per cent of relief), 30 per cent good (from 60 to 80 per cent of relief), 30 per cent fair (from 40 to 60 per cent of relief), 20 per cent, poor 20 per cent.

The author brings out quite correctly that skin tests must be supplemented by clinical study and that cyclic vomiting in infancy and early childhood may be and often is the forerunner of migraine or other allergic diseases. The book is well worth the attention of all interested in migraine and correctly points out that the treatment from the allergic point of view offers more to the patient than any other method so far discovered.

A Treatise on Materia Medica and Therapeutics including Pharmacy Dispensing Pharmacology and Administration of Drugs By the late Balbhadra Chosh. Thirteenth edition by Brendra Nath Ghosh F.R.F.I. & S. I. Prof. of Pharmacology Carmichael Medical College Calcutta. Cloth 180s Rs 7/8 1246d 1p 712 Calcutta Hilton & Company 1931

This edition has been brought up to the revision of the British Pharmacopoeia of 1932 and has assumed to a considerable extent the characteristics of British and American books on the subject. Nevertheless it shows local color as it contains tables of Indian domestic weights and measures. It reflects local experience in India as one can see from such treatments as: The usual dose of sodium aurothiosulphate (arsenicum) for Indian patients is smaller and the initial course should be as follows viz 0.1 0.2 Gm etc. In India azar

urea stibamine is especially recommended as giving the quickest results and being perhaps the best preparation. Interesting is part VIII, on "Indian Indigenous Drugs," in which some of the more important and more commonly used drugs of India are discussed. Thus one finds adhatoda, which by virtue of an alkaloid, "vasicine," relaxes bronchial muscles in the treatment of asthma, boerhaavia, the alkaloid of which, "punarnavine," acts as a diuretic in the treatment of dropsy, berberis, the alkaloid of which, "berberine," has been used successfully in the treatment of leishmaniasis, and kurchi, the alkaloid of which, "kurchicine," has a specific action on *Endamoeba histolytica* and is also of value in bacillary dysentery. Apparently, India still has some remedies that Western medicine might do well to investigate.

Blood Pictures. An Introduction to Clinical Hematology. By Cecil Price Jones M.D. Third edition. Cloth. Price \$2.10. 1 p. 71 with 12 illustrations. Baltimore: William Wood & Company, 1933.

There has been a distinct advance in hematologic information since the previous edition of this book twelve years ago. It was originally published to satisfy the need of the students and workers in clinical laboratories who desired such information and as a guide for clinicians in the interpretation of reports on blood examinations. Accordingly, clinical descriptions and treatment were for the most part omitted. The book is not intended for and is not a complete hematologic textbook. The author has purposely omitted the theoretical aspect of hematology. But the advisability of such a step is questioned. If the book were an atlas on blood pictures, such an omission would be understandable, but it does not seem plausible to present a guide for interpretation of blood without touching on some of the theoretical considerations. The plates of the blood cells are not well done. They are lacking in sufficient nuclear and cytoplasmic detail so necessary for successful recognition of the various types of cells. The illustrations do not seem to be sufficient for a work of this type. The book is divided into two parts. In the first part there are concise discussions on the technique of blood examinations and on the blood cells and the normal blood picture. The author's discussion of the normal blood appearances in infancy is totally inadequate. This is a serious omission, since they are totally different in this period of life from what they are in later childhood and adult life. The second part of the book is devoted to a discussion of blood pictures in the diagnoses of disease. There is doubtful virtue in the author's separation of bacterial infections into separate chapters on coccal, bacterial and protozoal etiology. In his introduction he states that the leukoid type of blood is associated with bacillary and lymphoid plus mononuclear type with protozoal infection. He modifies this by stating that other factors must be given consideration and then proceeds to discuss the response to bacterial infection without giving due stress to the modifying factors. Other chapters include discussions on blood diseases, the blood picture of malignant disease and hemocytometry. While the work is concise and presents many facts of interest, it is doubtful whether it will meet the needs of many students or physicians interested in hematology, even apart from its clinical applications.

Clinical Disorders of the Heart Beat. A Handbook for Practitioners and Students. By Sir Thomas Lewis CBE FRS MD Physician in Charge of Department of Clinical Research University College Hospital London. Seventh edition. Cloth. Price 6/6. Pp. 127 with 55 illustrations. London: Shaw & Sons Ltd. 1933.

This will be welcomed by students. Its authoritativeness and frequent editions have given this small handbook the distinction and dignity of a classic, reminding one of the frequent editions of Osler. The present edition compares well with its predecessors, containing even more keenly analytic clinical observations, evidence perhaps of a broadening and deepening of the author's bedside experience. In the preface one finds the statement that emphasis on the bedside recognition of cardiac irregularities, without graphic records, is a main objective. The book consists of eight chapters, each chapter, following the first, which is on the identification of disorders of the heart beat, discussing the most important seven forms of cardiac disorders, under the headings of sinus arrhythmia, heart block, premature contractions or extrasystoles, simple paroxysmal

tachycardia, auricular flutter, auricular fibrillation, and alternation of the heart. Each chapter follows more or less a similar grouping of topics: definition, nature of cardiac disorders, etiologic and pathologic relations, recognition, symptomatology, prognosis, treatment. Throughout, one is impressed by the simplicity, clarity and beauty of the text, as well as the continuous emphasis on the value of clinical data obtained at the patient's bedside. A number of minor criticisms are noted: the omission of the use of ephedrine in the treatment of heart block (p. 40), failure to mention the association of paroxysmal tachycardia with coronary thrombosis, nodal tachycardia, the difference in gravity and prognosis between auricular and ventricular paroxysmal tachycardia. As evidence of the beauty and dramatic quality of certain portions of the text, the following passage, from the section on prognosis of alternation of the heart, may be quoted: "Alternation of the pulse belongs to a small group of phenomena witnessed by those who attend the sick which treated as isolated signals, are in themselves emphatic and portentous. It ranks with subsultus tendimus with optic neuritis, with the risus sardonicus and other ill omened messengers. It is the faint cry of an anguished and fast failing muscle, which, when it comes, all should strain to hear, for it is not long repeated. A few months, a few years at most and the end comes."

The History and Epidemiology of Syphilis. By Wm. Allen Pusey M.D. LL.D. The Gehrman Lectures University of Illinois. M.D.CCCCXXXIII. Cloth. Price \$2. Pp. 113 with illustrations. Springfield: Charles C. Thomas, 1933.

This small but important book consists of three chapters of equal length, owing to the fact that it consists of three lectures given by the author under the Adolph Gehrman fund. The first lecture, on the beginning of syphilis, takes up the old argument as to the place of origin of the disease as considered from the European point of view. So convincing, apparently incontrovertible, is the evidence presented by Dr. Pusey that the old argument seems to be settled. Syphilis was imported into Europe from the West Indies by the members of Columbus's first expedition. It is an intensely interesting story. The quotation from the writing of Dias de Isla, a noted physician contemporary to Columbus, stating that "this serpentine disease" afflicting the sailors of Columbus was entirely unfamiliar to him and his colleagues, is a high point in this part of the story. A number of the oldest illustrations of syphilis are reproduced for this chapter. The second part on the development of knowledge concerning syphilis, is the story of the clinical study of the disease during the next 300 years. The author resents the insinuation that the men of medicine were slow to understand the facts of the disease and affirms his opinion that in view of the means at hand, they did a wonderfully good job. One is too apt to judge them without realizing the limitation of their basic knowledge and scientific appliances. Brief mention is made of the physicians prominent in this clinical study and of the particular service rendered by each one. Portraits of many of them are reproduced, and several pictures illustrate the early methods of treatment. Following this comes the story of the dramatic developments during the last century, the discoveries made possible by the aid of modern science. Prominent figures in this development are represented by portraits. The third chapter, on the epidemiology of syphilis, is equally interesting and instructive. Dr. Pusey agrees that 5 per cent of the whole population is a fair estimate of the prevalence of the disease in Great Britain and the United States and quotes Farrar's estimate that about 871,000 new cases occur each year in this country. The various methods of combating syphilis and the measure of their success are discussed. The author's optimistic attitude on this point is shown by his belief that, when the adoption of personal prophylaxis and the reduction of contagiousness by treatment become general, medicine can claim to have furnished means for the control in great part of the ravages of this hideous scourge of modern man. While not belittling the moral view of the question of prophylaxis, he emphasizes the overwhelming importance of physicians being governed by the medical needs of the situation. The clear, simple and concise style of the author is well known and nowhere more evident than in this book which is beautifully

printed and should be read by every physician and by every layman wise enough to be interested in this most important disease

The Thyroid Gland Its Chemistry and Physiology By Charles Robert Harrington M.A. Ph.D. F.R.S. Professor of Pathological Chemistry in the University of London. Cloth Price \$4.00 Pp 222 with 28 illustrations London Oxford University Press 1933

This is an authoritative presentation of the known facts and a discussion of the theories of the chemistry of the thyroid gland in relation to the physiology and pathology of the gland itself as well as to the general chemistry of the body. Probably nowhere in medical literature is to be found such a compact, simple and understandable presentation of the subject as is to be found in this monograph. Professor Harrington precedes the discussion of each phase of the subject by a historical sketch leading up to the present conception of the activity of the thyroid gland in both health and disease, and there is appended a valuable bibliography of important historical material since ancient times. The chapters dealing with the chemistry of thyroxine and its derivatives should be of interest to clinicians, since this highly technical subject is presented in as simple a manner as possible, as can be done only by a master of his subject. On the other hand, the chapters dealing with the more clinical phases of the subject also prove of interest to clinicians as representing a discussion of the subject from the chemical point of view. It is safe to say that all interested in the problems presented by the thyroid gland in both health and disease should be familiar with the material contained in this scholarly monograph.

Life Giving Light. By Charles Sheard Ph.D. Sc.D. Professor and Director of Biophysical Research the Mayo Foundation University of Minnesota and the Mayo Clinic. A Century of Progress Series. Cloth Price \$1. Pp 174 with 24 illustrations. Baltimore Williams & Wilkins Company in Cooperation with the Century of Progress Exposition 1933

In this volume the relationship of light to life is considered in a coordinated series of essays written in a delightfully conversational style. Not only the biologic and physiologic reaction to light of animal tissues and plant substance are dealt with, but also the physics of light, nonmathematically. Things scientific are explained in terms that should be understandable to an interested and inquiring layman. Being one of A Century of Progress Series, it is probably not intended as a textbook but it might well be recommended as parallel reading for the beginning student of biophysics. The contents deal with the history of artificial illumination, elements of the light spectrum measurements of light energy, lens, storing of light energy in plant and animal life, meaning of vitamins and, finally, a short, fanciful discussion on the mysteries of life.

La angina de pecho. Por Dr. Gregorio V. Martinez profesor de clinica médica de la Facultad de Córdoba. Cloth Pp 280 with illustrations. Buenos Aires Humberto Andreotta 1933

This excellent monograph is based on a painstaking study and analysis of the more important writings contained in the enormous literature of angina pectoris, as well as on personal investigation and clinical experience. After a few introductory paragraphs there are chapters on the historical aspects of the subject, clinical types, symptomatology, etiology, pathogenesis, prognosis and treatment. About forty pages is given to each of the topics symptomatology, pathogenesis and treatment. The volume concludes with about seventy pages devoted to the clinical histories and discussion of nearly fifty cases. The work is particularly suited to the special student of heart disease. The undergraduate or the general practitioner looking for guidance in the essentials of practice would not be interested in and might be bewildered by the somewhat lengthy consideration of various theories and the frequent citation of authorities with whose italicized names some of the pages fairly bristle. Most of the many illustrations are well executed and helpful electrocardiograms. In general the author's views are the commonly accepted ones that would be called sound. Some might not fully agree with his statement in his introductory chapter that the paroxysms of angina pectoris are in the majority of cases accompanied by histologic and chemical change in the blood, sclerotic manifestations in the arteries and characteristic alterations of the electrocardiogram. It is

to be noted however, that under the caption of angina lie is including those cases in which there is coronary thrombosis. Martinez is an adherent of the coronary artery theory of angina pectoris, as will be seen from the following quotation: "As anatomic-pathologic substratum of this affection one must really accept a histochemical change in the coronary arteries and a special sensitiveness of the plexuses of nerves that accompany them" (p. 7).

Actinotherapy Technique. An Outline of Indications and Methods for the Use of Modern Light Therapy. With a foreword by Sir Henry Gauvain M.D. M.Chir. F.R.C.S. Fabrikhold Price \$1. Pp 184. Slough England Solut Publishing Company 1933

Since the introduction of this book is signed "Hanovia" it can be regarded as a publication edited by the manufacturer of Hanovia Ultraviolet Lamps. The book is divided into three parts. Part I contains five chapters, one a good but short chapter of physical data on mercury vapor lamps, another a mediocre discussion on physiologic effects, two mediocre chapters on ultraviolet dosage, and a short chapter on luminous heat and infra-red rays. Part II contains indications and details of technic, and part III is a supplementary list of books and papers. Of the 920 references given, a large portion refer to reliable research, while others are of doubtful value. More than half the book is devoted to indications and technic. Between abscesses and xanthoma there are more than 200 indications given for the use of ultraviolet radiation. Many of the indications and statements are not accepted by the medical profession generally. For example, one finds statements, such as "Chorea. Irradiation rapidly mitigates symptoms and relieves insomnia", "Diabetes. Good results are obtained in cases of glycosuria", "Goitre and Exophthalmic Goitre. In early cases benefit frequently follows on the use of actinotherapy", "Osteomyelitis. American writers report complete healing of the sinus after a few local treatments, combined with a Tonic Course of general irradiation". Such statements and others like them identify this book as of little value to the general practitioner seeking scientific information regarding the practice of ultraviolet therapy.

Red Blood Cell Diameters. By Cecil Price Jones M.D. Cloth Price \$3.50. Pp 82 with 44 illustrations. New York & London Oxford University Press 1933

Much of the recent progress in the study of anemia and grouping for therapeutic purposes has followed advances in the scientific development of hemocytometry. The data obtained by measuring the red cell diameter in certain types of anemia are now used for diagnosis and in following the course of therapy. The author has been one of the most active contributors in this field and is particularly well qualified to present the subject. He has given a concise and scholarly summary. The introduction is concerned with a historical review of the scientific study of the erythrocyte and its measurement. The technic of hemocytometry is fully described and the normal, physiologic variations and pathologic significance are clearly indicated. The work is an excellent summary of mathematically controlled observations in normal and anemic subjects, which combines not only the work of the author but other workers in the field as well. It is highly recommended as an authoritative source of information on hemocytometry and some of its clinical applications.

Handbuch der Inneren Sekretion. Eine umfassende Darstellung der Anatomie Physiologie und Pathologie der endokrinen Drüsen. Herausgegeben von Dr. Max Hirsch. Band II. Lieferung 10. Die Physiologie des Hodens. Von Prof. Dr. Knud Sand. Laper Price 43.50 marks. Pp 2017 2300 with 110 illustrations. Leipzig Curt Kabitzsch 1933

This section is written by Prof. Knud Sand of Copenhagen and constitutes in reality a monograph on the physiology of the testis. Professor Sand has himself made important contributions in this field particularly on birds and this work discloses the hand of a master and true scientist in clarity of exposition, selection of illustrated material and analysis of controversial data. Informed readers will finish the volume with the regret that the author did not include chapters on the relation of the testis mechanism to some of the other glands of internal secretion. Professor Sand's contribution ranks as one of the best in the large handbook.

Medicolegal

Malpractice Burns from Diagnostic Use of Roentgen Ray, Standard of Care Not Dependent on Locality—The defendant-physicians made fluoroscopic examinations of the plaintiff's hand with a view to the removal of a needle Burns followed The plaintiff brought suit, alleging negligence The trial court set aside a verdict in favor of the defendants and ordered a new trial The defendants thereupon appealed to the Supreme Court of Oregon

The plaintiff testified that in accordance with instructions from the defendants she held her hand in front of a fluoroscope, at a distance of 10 inches for from fifteen to twenty minutes, and that after a lapse of five or six minutes the fluoroscope was again used five or six times, the duration of the several exposures being the same The defendants admitted that five or six fluoroscopic examinations were made, but they asserted that no exposure lasted more than ten seconds The question, said the Supreme Court, is, Did the defendants fail to exercise reasonable care in their use of the x-ray machine? The undisputed evidence showed that if the exposures were made in the manner alleged by the patient, they were improper and injury would result The defendant-physicians however, contended that they did not expose their patient's hand to an overdose of roentgen rays and that the condition of her hand was due to an infection

A physician and surgeon, said the Supreme Court is not a guarantor of results Ordinarily however, he impliedly contracts that he will exercise the degree of care and skill usually possessed and exercised by those engaged in the same line of practice in similar localities As a general rule, the degree of care and skill depends somewhat on locality But the duration of exposure, especially when the roentgen rays are not used for treatment, has become so fixed and exact that physicians are cognizant of it, whether they practice in Pumpkin Center or in New York City It would be negligence for a physician to expose a patient to roentgen rays for the length of time claimed by the plaintiff regardless of the locality in which the physician was practicing The trial court instructed the jury that the defendants were to be judged not by the standard of care employed in all localities but by the standard which is employed by physicians "in localities like Ramier and similar localities" Although this instruction was correct as a statement of the general rule, said the Supreme Court, it was, as applied to the facts of this case, misleading and prejudicial The patient was entitled to have the jury instructed that in the use of their x-ray machine the defendant physicians were to be judged according to the standard of care, skill and diligence that would have been exercised by "a physician and surgeon of ordinary care, skill and diligence," under the same circumstances and conditions, *regardless of locality*

The authorities are in conflict as to whether negligence may be inferred solely from the fact that a roentgen burn has occurred In the present case, said the Supreme Court, it is not necessary to invoke such a doctrine, since there was testimony tending to show an improper exposure The trial court instructed the jury that the fact that the hand was burned by the roentgen rays was no evidence that the physicians were guilty of malpractice This instruction was technically correct, but it may have misled the jury into the belief that the burn could not be taken into consideration along with other facts and circumstances The jury was entitled to consider the alleged roentgen burn together with the evidence relating to the duration of exposure The instruction should have been amplified The same can be said, continued the court, with respect to the instruction of the trial court that "a physician or surgeon practicing his profession is not liable for errors or mistakes of judgment" A physician or surgeon is not liable for error of judgment, if the exercise of judgment is consistent with the exercise of reasonable care and diligence But if the defendant-physicians, in the use of their x-ray machine, failed to follow the formula relative to the time of exposure universally accepted by the profession, it would not do for them, in order to avoid liability, to say "We exercised

our best judgment" To avoid liability, the judgment must be based on the exercise of reasonable care and skill

The instructions given by the trial court, considered in their entirety, concluded the Supreme Court, are open to criticism and the trial court was warranted in setting aside the verdict of the jury and granting the plaintiff a new trial—*King v Ditto (Ore)*, 19 P (2d) 1100

Evidence Verdict of Coroner's Jury Inadmissible—Blackwell was tried for murder In the course of his trial a justice of the peace, who had acted as coroner when the homicide occurred, testified, over objection by the defendant, that he had caused an inquest to be held over the body of the deceased and the entire record of the inquest was read in evidence Blackwell was convicted He appealed to the Court of Appeals of Alabama, claiming that the admission of the record of the inquest was error

The statutory proceedings of a coroner's inquest are wholly ex parte, said the Court of Appeal The verdict of a coroner's jury is not binding on the defendant on trial for the alleged murder To try the defendant on the ex parte verdict of a coroner's jury would deprive him of his right to be confronted with the witnesses against him and to cross examine them The verdict of the coroner's jury in the present case may or may not have been based on evidence receivable in courts of justice In cases of homicide, said the court quoting Ruling Case Law, vol 6, p 1172 the general rule is that the finding of a coroner or the verdict of a coroner's jury is not admissible in evidence for any purpose The only object of a coroner's proceeding is to furnish prompt information that may guide the officers of the law in apprehending and prosecuting persons who appear to have been connected with a supposed homicide and to discover the evidence by which it may be investigated Strictly speaking, the verdict of a coroner's jury has no legal effect To admit the verdict and proceedings in evidence in a prosecution for homicide would lead to the subversion and final overthrow of the jury system and in nearly every case the rights of the commonwealth or of the accused would be prejudiced The judgment of conviction in the trial court was therefore reversed and the case remanded—*Blackwell v State (Miss)* 146 So 628

Evidence Angina Pectoris a Disease of the Heart—The appellant insurance company insured the life of the deceased It limited its liability, however, to a return of the premiums paid, if the insured died from heart disease within one year from the date of the policy The insured died within the year The death certificate stated the primary cause of death as angina pectoris with chronic arteritis as a contributing cause The beneficiary of the policy insisted that the words "angina pectoris" denote only a symptom and not a disease of the heart and brought suit From a judgment in favor of the beneficiary the insurer appealed to the Supreme Court of Alabama A medical expert testified that the words "angina pectoris" mean a pain in the chest But you have got to have heart disease he testified, to have angina pectoris, angina pectoris is really a name for heart disease In Corpus Juris vol 2, p 1346, angina pectoris is described as a disease of the heart The Supreme Court of Alabama concluded, therefore that angina pectoris is a disease of the heart and that that is the commonly accepted meaning of the term The judgment in favor of the beneficiary was reversed and the case remanded—*Liberty Nat Life Ins Co v Tellis (Ala)* 146 So 616

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers to THE JOURNAL in continental United States and Canada for a period of three days. Periodicals are available from 1925 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

- Sarcomatous Degeneration of Uterine Leiomyoma with Metastases to Lungs and Heart Case M Criscitello Jr Pittsfield Mass—p 919
- Role of Sodium Potassium Calcium and Magnesium in Cancer Review M J Shear Boston—p 924

Effect of Radon on Pancreas of Dogs—Leven describes experiments on dogs which indicate that implantation of radon into the pancreas would be a safe procedure in suitable cases of carcinoma of the pancreas at the time of exploration or secondary to cholecystogastrostomy. Radon in gold seeds would be preferable to high voltage roentgen therapy, since the effect can be more accurately directed to the desired area. That the pancreas has definite power of regeneration has been adequately indicated experimentally. This should prove to be an additional factor of safety in the use of radiotherapy in carcinoma of the pancreas. The author states that his experiments should not be considered as constituting a claim that carcinoma of the pancreas can necessarily be cured by radiation.

Sarcomatous Degeneration of Leiomyoma—Criscitello presents a case of sarcomatous degeneration of uterine leiomyoma with unusual metastases to the lungs and the heart. Recognition of malignant changes should be attempted in the operating room by routine opening of all fibromatous tumors removed. If such changes are recognized a more radical operation is in order. Sarcomatous degeneration of fibromyomas is not rare. The incidence, as reported by different writers varies from 0.5 to as much as 10 per cent. Some authors deny that such malignant changes take place and claim that if a sarcoma develops from a preexisting fibroma or myoma it is due not to a degenerative process but to the development of a primary focus of a malignant condition. Although metastases from sarcoma of the uterus to the different organs and bones have been reported metastases to the heart are exceedingly rare.

Roentgen Observations in Suppuration of Petrous Apex—Taylor states that for the demonstration of suppuration in the petrous apex the most information is obtained from a roentgenogram of the base of the skull, because the two pyramids are depicted at the same time and are contrasted by the surrounding bony structures and show their structural character and detail more clearly. The routine examination of the mastoid processes includes one view of the base of the skull. Should a complicating petrous suppuration develop, the original roentgenogram of the petrous bones is available for comparison with subsequent roentgenograms, permitting the detection of the earliest changes. The patient should be supine when the roentgenogram is being taken with the head, lower than the rest of the body, resting on the vertex, so that a line drawn through the external auditory canal and superior orbital margin is parallel to the cassette, which is horizontal. The sagittal plane of the head should be perpendicular to the table. The tube should be tilted upward 15 degrees. The central ray should be directed 1 inch in front of the external auditory canal, in the midline. The same position can be accomplished by hyperextending the body, a block being used as a support in the mid and lower dorsal regions, the elevation being about 8 inches. Suppuration in the apical portion of the petrous pyramid can be recognized clinically and roentgenologically. The clinical recognition depends on profuse otorrhea occurring after a period of cessation, following a simple mastoidectomy, pain along the distribution of the ophthalmic branch of the fifth nerve, retro-orbital and low grade sepsis. The roentgen observations are diminished aeration, deficient trabeculations, intense atrophy, perforation and finally destruction of the apical contour. These changes occur only in pneumatized petrous pyramids. Operation is indicated when clinical symptoms and roentgenologic observations are present. In cases showing positive roentgenologic observations and no clinical symptoms the drainage is adequate and if operation is not performed probably there will finally be a protracted otorrhea.

Auditory Effects of Roentgen Rays—Girden and Culler exposed two dogs to a variety of doses over a period of months so as to determine the effects of the roentgen rays on their auditory acuity. From their observations the authors suggest

the conditioned response technic as a means of direct study of the effects of roentgen rays on hearing in dogs. By means of this approach, accurate investigation of the effects of roentgen rays on hearing itself is permitted. In the animals reported on, as well as in subsequent studies nearing completion an initial rise in auditory acuity results from exposure to small doses of roentgen rays generated at 85 kilovolts and 5 milliamperes. This increase in acuity is a transient effect lasting from two to four weeks. Cumulated doses up to 11,100 roentgens in one animal and over 4,400 in another did not result in death and did not impair the hearing. The skin burns were due to overexposure to soft rays. Spacing of the larger doses over longer periods of time avoids this hazard. The authors' investigation is being widened to include the study of the effects at higher voltages and also, by means of the oscillograph technic, the direct effect on the nervous mechanism involved in audition.

Gastric and Duodenal Ulcers.—Shuman reports a consecutive series of 227 cases of acute perforated gastric and duodenal ulcers in which operation was performed. Less than 2 per cent of the patients were women, the average age was 37 years. Perforations increased in frequency during the spring, reached a peak number in the summer, gradually decreased in number during the autumn, and reached the lowest rate in the winter months. As compared with the total number of operations done in the author's hospital during the period of thirteen years covered in his report, operations for perforated gastric and duodenal ulcers have increased in frequency nearly threefold. A definite history of chronic gastric ulcer was obtained in more than 80 per cent of the cases, and 10 per cent had had medical management. Severe pain in the epigastrium was the typical initial symptom. Vomiting occurred once or twice in about 50 per cent. Bloody vomitus was a rarity. The clinical observations were of far greater comparative value than those of the laboratory. Among the latter, fluoroscopic examination is the exception. On admission to the hospital, 85 per cent were immediately and correctly diagnosed. The mortality increased directly with the size of the opening, the amount and extent of the peritoneal soiling and the time allowed to elapse between rupture and operative treatment. Frequency of perforation, according to the location of the ulcer, was respectively duodenal, gastric and pyloric. Recovery was in the same sequence. The proportion of recovery remained nearly stationary for all ages between the second and sixth decades, 36 per cent died within the first twenty-four hours after operation. General peritonitis was the most frequent cause of death, then came shock, pneumonia and complications requiring secondary operations. Spinal anesthesia was the most satisfactory. Operative treatment, while individualized, was confined to simple closure, excision and closure, and closure with added gastrojejunostomy. Simple closure was employed in the last 132 cases with a 10 per cent reduction in mortality. Of these 227 patients 55 or 24.22 per cent, died and 172 or 75.77 per cent, recovered.

External Gastro-Intestinal Fistulas.—Co-Tui established by experiments on the dog that trypsin can cause skin excoriations.

He treated 162 cases of peristomal excoriations with kaolin powder. The principle of the treatment is the removal of the enzyme trypsin by kaolin particles because of a difference in their electrical charge. A plentiful amount of kaolin powder is applied over the mouth of the fistula and all around it. The number of changes necessary depends on the condition of the abdominal wall and the amount of drainage. A safe rule is to change the powder as soon as it becomes saturated. In duodenal fistulas it is generally necessary to change the powder from every hour to every three hours, in ileostomies from four to six hours, in cecostomies, from four to eight hours, and in sigmoidostomies twice a day. It must be borne in mind that the success of the treatment depends on the removal of as much of the enzyme as the fistula discharges. The application of petrolatum to the abdominal wall before using the powder defeats the purpose for which kaolin is used, as the petrolatum coated particles of kaolin then become electrically inert.

Cholesterol in Schizophrenia.—Looney and Childs observed approximately fifty men presenting schizophrenia over a period of seven months at intervals of two weeks and of three months. The cholesterol content of the whole blood was determined by the method of Myers and Wardell. The mean cholesterol values were 146 ± 3 mg per hundred cubic centimeters for the first period, 161 ± 28 mg for the second period and 166 ± 25 mg for the third period. The mean value for twenty-six normal men was 175 ± 52 mg per hundred cubic centimeters. Both the schizophrenic patients and the controls showed great variability in the cholesterol values, the former having a standard deviation of about 20 mg and the latter of 27 mg. The difference between the mean value for the first period and the mean values for the last two periods is believed to be due to a seasonal variation in the cholesterol content of the blood. No correlations could be shown between the blood cholesterol and the basal metabolic rate or the emotional status. Schizophrenia seems to be characterized by a slight degree of depression of the cholesterol content of the blood.

Value of Immune Serum in Poliomyelitis.—Sutton reports an outbreak of nineteen cases of poliomyelitis, eighteen of which were treated with convalescent serum. Of the eighteen, serum was administered to thirteen (group A) in a definitely preparalytic stage, to two (group B) in the late preparalytic stage, and to three (group C) in the early paralytic stage. An examination of these patients eight months later presented the following results. In group A there was a 100 per cent recovery with no paralysis. One patient in group B showed no paralysis. The other one showed complete recovery in the abdominal muscles and in three of the four extremities involved.

The left shoulder showed little or no improvement. This was a fulminant case, with 50 per cent recovery. The three patients in group C showed recovery to a marked degree in the less severely affected muscles, so that each patient will have only one extremity that will not function usefully. All can become self supporting. The one patient who did not receive serum, because he was seen too late, will be badly incapacitated and probably dependent.

Iodine Therapy in Hyperthyroidism—Poer states that iodine will produce a remission in from 80 to 90 per cent of all cases of hyperthyroidism. The remission begins within forty-eight to seventy-two hours and reaches the point of maximum response in from ten to eighteen days. A dose of 6 mg. of iodine a day is necessary to produce the maximum response, a larger dose is advocated to insure this maximum benefit. Because of the similarity of response to iodine in both the hyperthyroidism associated with exophthalmic goiter and that appearing in toxic adenomas it may be said that the proper use of iodine is an adequate dose (5 drops daily at least), given over a period of from ten to eighteen days until the point of maximum response is reached, at this point operation should be performed. Because of the dangers of postiodine reactions, development of refractoriness to iodine, the inability to cure hyperthyroidism permanently and the loss of its beneficial action in postoperative crises, iodine should not be used in any other manner in hyperthyroidism. If for any reason it becomes necessary to postpone or delay operation iodine should not be administered until these reasons have been removed. A strictly medical regimen consisting of rest in bed, sedatives, ice caps and such local treatments as are indicated should be instituted until the patient is prepared for the surgical procedure. Iodine has no place in the treatment of the physiologic enlargement of the thyroid during puberty and early adolescence in women, its indiscriminate use in foods, patent remedies, water and so on, is unscientific and dangerous.

Id. V. Presence of Meningococcus Precipitinogens in Cerebrospinal Fluid G. Rake New York—p 375

Epidemiology of Tuberculosis—Lurie states that 73 per cent of normal rabbits exposed for about one year to cage mates infected with tubercle bacilli of bovine type acquired a respiratory or alimentary tuberculosis that was fatal in 50 per cent, 63.6 per cent developing tuberculosis during the first six months. Of the rabbits vaccinated with tubercle bacilli of human type and exposed in the same cages at the same time, only 36.8 per cent acquired tuberculosis during the first six months. Later this resistance waned, and by the end of the year 60 per cent had developed tuberculosis, of which 38 per cent succumbed. The disease in the vaccinated rabbits was shown to be of exogenous origin by the isolation in pure culture from the same rabbit of the human type bacillus from the primary infection and of the bovine type bacillus from the naturally acquired lesion. The vaccination reduced the incidence, extent and mortality of the disease, affected the route of infection, changed its pathologic character and retarded its progress. The disease acquired by vaccinated rabbits shared many characteristics with the adult type of tuberculosis in man.

Meningococcus Precipitinogens in Cerebrospinal Fluid—Rake points out that precipitin tests, carried out on the cerebrospinal fluid from cases of meningococcal meningitis with monovalent serums, demonstrate the presence in that fluid of type specific precipitinogens of the meningococcus. Negative results are secured when the spinal fluid is obtained after the commencement of intrathecal serum treatment and also occasionally when the numbers of infecting organisms are small. The reaction offers an easy and rapid method of ascertaining to which type of meningococcus a particular case of meningitis is due and facilitates the immediate use of monovalent therapeutic antimeningococcus serum. Typing by means of the precipitin reaction can be confirmed by agglutination of the strain of organism responsible for the infection, if such a strain is isolated. Confirmation by means of agglutination has been possible in all the author's cases. Spinal fluids from other diseases of the meninges and the central nervous system fail to give any precipitin reaction with the monovalent serums.

Vaccine Therapy and Arthritis—Marvin used vaccine therapy in only thirty-five patients although he has treated more than 125 cases of arthritis. His aim has been to select moderately severe to severe cases of acute and chronic infectious arthritis, that is those patients who had been treated for a reasonable period with other forms of treatment and had shown little or no improvement and similar cases in which improvement was expected slowly without vaccine. Although his series of cases is small, the author feels that intravenous vaccine is most beneficial in the treatment of both the acute and chronic infectious types of arthritis. He realizes that from 75 to 80 per cent of all arthritides become sufficiently improved under ordinary types of therapy for the patients to resume their occupations and carry on their normal everyday life. Intravenous streptococcus vaccine is an important addition to other forms of treatment, hastening the recovery in many cases and materially helping many of the remaining 20 or 25 per cent. The author has given weekly intravenous injections of Cecil's stock *Streptococcus viridans* cultures in a vaccine diluted to 125 million killed bacteria per cubic centimeter. His results have been such that he hopes to use this treatment in addition to other forms of therapy, in all his cases of infectious arthritis in the future. He believes that this treatment will be universally used in the near future and will become one of the standard therapeutic measures in the treatment of most cases of infectious arthritis.

Hepatic Cirrhosis and Insulin—McCabe and Hart report the results obtained in five patients suffering from hepatic cirrhosis with ascites who were put on a high carbohydrate

diet and as much insulin as they could take comfortably. One of the patients has remained on the high carbohydrate diet through his own choice, yet five years has passed without a return of the ascites. Another patient responded so quickly to the treatment that the authors feel that the endogenous toxin was benign. In another patient there was a definite alcoholic history for thirty years. After a year and a half of treatment the patient stated that he felt strong and was anxious to resume work. About two years after the beginning of treatment all laboratory tests were normal. Examination showed that the patient was in excellent condition without ascites, and that 168 days had elapsed since the last tapping. In the fourth patient one with definite syphilitic cirrhosis, the authors feel that the arsenic was detrimental. This was the only patient in whom insulin caused shock. On the last examination the patient was emaciated and was being tapped about every two weeks. In the last patient the entrance diagnosis of hepatitis or subacute yellow atrophy with cholemia was justified from the history. The use of intravenous dextrose and insulin, although in limited amounts, seems to have been specific. The patient improved and his jaundice faded. Decompensation, however, set in about six weeks after the initial symptoms of the disease. The authors do not offer this treatment as a cure of hepatic cirrhosis nor do they offer it as a permanent cure of the ascites because they realize that longer periods of observation and postmortem studies must be made. What they do believe is that it will reestablish compensation in some cases and lower the transudation in others so that the intervals between tapping may be extended.

Toxicity of Arspenamine—Rosenthal and Prober determined the arsenoxide content and toxicity of thirty-five recent samples of arspenamine. A correlation sufficiently close was obtained to attribute the enhanced toxicity of certain products chiefly to arsenoxide. Eleven samples of arspenamine from 3 to 10 years of age originally of low toxicity, were studied. With the exception of one product an increase of toxicity roughly proportionate to the age was found. Sufficient arsen oxide was present to account for the increases in toxicity. The authors describe a color reaction between neorsphenamine and lead acetate which detects chemical differences between various products and a simple test (the tungstic acid color test) to distinguish between arspenamine neorsphenamine and sulph arspenamine.

Toxic Effects of Staphylococcus Filtrates—Borthwick records his experiments which illustrate how rabbits and guinea-pigs may be protected normally against staphylococcus toxin when it is introduced directly into the alimentary tract. The results suggest that the inactivating effect of the acid contents of the stomach is an essential factor in this protection and explain the failure of previous workers to reproduce experimentally in these animals the condition of "food poisoning" by staphylococcus toxin as observed in the human subject. The sensitiveness of this toxin to slightly acid or alkaline reactions is of special interest. On the other hand, the local and general toxic effects produced by staphylococcus filtrates introduced into the stomach of guinea-pigs after neutralization of the contents afford an interesting demonstration that the toxins of staphylococci growing in certain articles of food may produce serious poisoning. It seems likely also that the hydrogen ion concentration of the stomach contents is a factor that determines the occurrence of such poisoning in the human subject and this may explain the variable results observed by Jordan and Hall when volunteers were fed with milk containing staphylococcus toxin. The experiments indicate how, under certain conditions small laboratory animals can be utilized for further inquiry into this form of food poisoning, and may have a more general application in the study of the effects of other bacterial toxins on the alimentary tract. The author observed that when staphylococcus toxin is added to the gastric contents in vitro a slightly acid (pH 6.8) or a slightly alkaline (pH 7.8) reaction impairs its activity whereas no inactivation occurs at pH 7.3. Symptoms of poisoning can be produced only occasionally in guinea pigs and rabbits when toxin is introduced directly into the stomach. Uniformly positive results are obtained in experiments in which the reaction of the stomach is adjusted to pH 7.3 at the time of introduction of the toxin. The animals die within five days and post-mortem examinations show signs of acute gastro-enteritis and marked congestion of the internal organs associated with hemorrhage in the stomach and kidneys. Symptoms of poisoning can be produced by intrarectal inoculation of the toxin when the rectum has been irrigated with saline solution and the reaction adjusted to pH 7.3. Post-mortem features are similar to those obtained after the introduction of toxin into the stomach. This method is not so effective as inoculation into the stomach.

Symptomatology of Yaws in Liberia Details of Statistical Method Used in This Study G W Harley —p 235

Meinicke Turbidity Reaction—Todd presents a simple substitute for the Meinicke turbidity reaction, in which to 3 drops of serum he adds 1 cc of Meinicke's turbidity reagent after diluting it at 50°C with ten times its volume of a 3 per cent solution of sodium chloride and a 0.01 per cent solution of sodium carbonate. He compares this with the control tube, to which has been added 1 drop of formaldehyde. A double positive reaction after five to ten minutes is turbid, after three to six hours it is clear, and after eighteen to thirty hours it is clear also. A weak positive reaction after five to ten minutes equals the control after three to six hours it is turbid, and after eighteen to thirty hours it is clear. A doubtful reaction is doubtful after five to ten minutes equals the control after three to six hours and is clearer than the control after eighteen to thirty hours. A negative reaction is doubtful after five to ten minutes and after three to six hours, and equals the control after eighteen to thirty hours.

Suprarenotropic Hormone—Collip and his associates present proof that the suprarenotropic principle as obtained in refined extracts is distinct from the thyrotropic principle. The hypophysectomized rat is a satisfactory test animal for detecting the presence of the suprarenotropic hormone. They report a series of tests on 125 rats which were completely hypophysectomized: (1) loss of weight following hypophysectomy, (2) complete failure to grow, (3) atrophy of the left suprarenal removed for control examination before starting the injections and (4) absence of any fragments of the pituitary by careful inspection at the time of necropsy. In some of the animals the authors have had further evidence of the completeness of the hypophysectomy by determining the basal metabolic rates and by serial sections of the sella turcica. The animals used were hypophysectomized from eleven to 148 days previously. Before starting the injections the left suprarenal was removed, weighed and sectioned for histologic examination. Removal of one suprarenal from the hypophysectomized rat is not followed by a compensatory hypertrophy of the other suprarenal, such as occurs in the normal animal. In six control animals from which the left suprarenal was removed from eight to twenty-three days after hypophysectomy and the right suprarenal one week later, the right suprarenal in each case weighed either the same as or less than the left suprarenal of the same animal and all showed marked atrophy of the cortex by histologic examination. In another group of seven hypophysectomized animals receiving Witte's peptone (20 mg daily) or extracts of anterior pituitary free from the suprarenotropic hormone there was no evidence of any repair of the atrophy that is seen in the untreated hypophysectomized rat. Of forty different extracts of the anterior pituitary lobe that have been tested thirty-four were found to contain the suprarenotropic hormone. Eight of these extracts show a fairly high degree of potency causing an increase of from 50 to 300 per cent in the weight of the right suprarenal over that of the left suprarenal which had been removed previously as a control. In 10 of the extracts that have been assayed brought about repair of the suprarenal in the hypophysectomized rat when 0.025 cc (0.125 mg of total solids) was administered twice a day for one week. Four extracts with a high degree of potency showed no trace of the thyrotropic hormone. The extracts had no effect on the growth of the body. Extracts boiled for thirty minutes still showed suprarenotropic activity. Active extracts were found to be ineffective when administered orally. The

authors obtained the purest extracts of the suprarenotropic principle from a fine flocculence, which has separated out on concentrating a 75 per cent acetone-soluble fraction at from μ 5 to 6. The latter has been obtained as a by-product in the purification of the thyrotropic fraction in the filtrate of the original aqueous extract after the tricalcium phosphate adsorption treatment to remove growth hormone, as in the Q process.

Dinitro-Orthocresol as Stimulator of Metabolism—Dodds and Pope, in investigating the pharmacologic action of the nitrophenols as stimulators of metabolism, observed the oxygen consumption of guinea pigs by a modified Krogh technique and, when a steady figure had been obtained for the basal rate, the substance to be tested was injected, or alternatively administered by mouth, and the effect on both temperature and oxygen consumption was studied. Of the many compounds investigated, dinitro orthocresol appears to be the most promising. For example, the basal oxygen consumption rate of the guinea pig, measured in cubic centimeters per gram weight of guinea pig per minute, was 0.0135 and the temperature was 97 F. Dinitro-orthocresol (8 mg.) dissolved in sesame oil was administered by subcutaneous injection. One hour afterward the oxygen consumption rose to 0.0376 cc. per minute and the temperature to 100.9 F. Four hours later the temperature had reached 102.8 F. Similar experiments with 2,4-dinitrophenol produced a rise of about one third the magnitude. Observations on the toxicity of these two compounds indicated that they are of the same order. Both compounds are active when administered by mouth. The authors believe that the dinitro-orthocresol compound is more suitable for clinical experimentation, since about one third of the amount is required to produce the same effect as with the dinitrophenol. The authors are now investigating the clinical application of these compounds.

Bendien and Sedimentation Tests in Prognosis of Tuberculosis—Fine and Dunlop carried out 151 Bendien tests, most of them simultaneously with a sedimentation test in thirty-six cases of pulmonary tuberculosis. In most of them the blood was examined from five to ten times. The results reveal a high degree of correspondence between (1) the Bendien and the sedimentation tests, (2) the clinical course and the prognosis and the prognostic tests. While there is no reason to believe the Bendien test either more or less accurate than the sedimentation rate, it has the following advantages: 1. It is a serum test, and therefore more convenient. 2. It does not show so readily minor fluctuations, and therefore its variations are more significant. It has the disadvantage of requiring two very accurately prepared reagents. In the preparation of the acetic acid solution an error of tenth normal $\times (\pm 0.005)$ causes a displacement in the result by one tube. Sodium vanadate varies in the amount of water of crystallization, and the tenth normal solution can therefore be safely prepared only by obtaining the weight of the anhydrous salt. The Bendien chemical test is a useful prognostic test in pulmonary tuberculosis and probably in other conditions in which the sedimentation rate has been found useful. It may safely be adopted as an alternative prognostic test when the sedimentation rate is impracticable.

Precipitin Reactions in Rheumatic Patients—Schlesinger and Signy state that streptococcus precipitins can be demonstrated in the blood of rheumatic patients following acute streptococcal throat infections. The group of cases in which the investigations were carried out consists of seventeen rheumatic and four nonrheumatic children. The formation of precipitins is delayed until the second to fourth week from the onset of the nasopharyngeal infection (the end of the silent period), and their appearance in most cases foreshadows a tendency to a relapse of acute rheumatism. The precipitin corresponds to the type of streptococcus responsible for the throat infection, but a certain amount of cross precipitin formation may occur. The formation of precipitin is regarded as one of the manifold reactions that take place in the patient's defense mechanism during the silent period. There is thus time for prophylactic measures if the throat infection has not passed unnoticed. Concentrated acetylsalicylic acid therapy during this period undoubtedly prevents serious relapses in many cases. The technique adopted for the precipitin test was modified so as to make the best use of small amounts of serum. The antigen used was that described by Collis. It consists of a filtered saline emulsion of ground streptococci. Standard dilutions of the patients' serum to be tested were made. In the early part of the work a 1:10 dilution was used, but later it was found that a 1:5 dilution gave better results. One cubic centimeter of this serum was put up against 1 cc. of falling dilutions of the antigen: 1:5, 1:10, 1:20 and 1:40. Dilutions were at first made both with physiologic solution of sodium chloride and with a 0.2 per cent solution of sodium chloride, but, as no differences were noted, physiologic solution of sodium chloride only was used in the later tests. The results were usually definite after an incubation of twelve hours in a water bath kept at 37 C. A control tube of serum and saline solution was always used and occasionally showed turbidity after incubation. When this occurred, the serum was discarded as unsuitable for the test. The positive reactions were never heavy precipitates. A flocculent deposit with a clouding of the supernatant fluid was taken to denote a strong positive reaction, while a mere clouding with or without a slight deposit in one or two tubes was read as a weak positive reaction, provided always the control tube remained clear. Reactions were more frequently observed in the tubes containing the more concentrated antigen and never showed a zone phenomenon.

Diabetic Lipemia—Collins recommends describes and discusses Ruckert's hemolipokrit method for the volumetric estimation of fat in blood serum in diabetic lipemia. He records the result of serum fat estimations on 103 diabetic and fifty-five nondiabetic blood samples. Increase of the serum fats is associated with the presence of glycosuria and acetoneuria and with the clinically severer cases of diabetes in particular. No clear relationship could be established between the serum fat and the blood sugar level. There was no relation between the serum fat and the weight of the body of the patient. The author discusses a case of diabetes with hyperthyroidism and suggests the value of a serum fat determination as an aid to diagnosis. He expresses the opinion that the lipemia of diabetes is solely dependent on the inhibition of carbohydrate metabolism and that the increased amount of fat in the blood is evidence of a mobilization of fat in response to the caloric requirements of the body.

Spondylolysis Its Causes and Consequences—

Roederer and Glorieux define spondylolysis as a unilateral or bilateral interruption in the continuity of the posterior vertebral arc passing between the superior and inferior articular processes. While the lesion may sometimes be demonstrated roentgenographically in front exposures and, rarely, in profile exposures, it is always demonstrable in three quarter exposures although several exposures may be required. It may present itself as a real interruption of continuity, but more often it is merely an unhooking or lack of alinement in the trabeculation. In the authors' opinion spondylolysis may often be congenital, but it is also frequently produced by trauma. In traumatic spondylolysis the mechanism is as follows. At first there is a hyperextension of the spine with the center of the intervertebral disk serving as the axis, the extension continues with the inferior articular process of the fifth lumbar vertebra and the superior process of the first sacral vertebra, for example, serving as axis, finally the articular processes touch, blocking extension, so that, if the movement is accentuated, the isthmus of the fifth lumbar vertebra (the point of least resistance) breaks. The authors have found these lesions in 40 per cent of patients complaining of incapacity for effort after a trauma with hyperextension. Spondylolysis plays an important part in the production of spondylolisthesis and precedes or accompanies it in practically all cases. A spondylolysis, whether congenital or acquired, may give rise to pains of static origin. The fibrous tissue, which joins the fragments forcibly subjected to violent traction, may be stretched on one or both sides and permit a slipping with or without rotation of the entire upper part of the spinal column. The permanent muscular effort needed to diminish this abnormal mobility and the contraction which develops may cause pain. Certain severe scolioses starting in the inferior lumbar region result from a spondylolysis with a slight slipping which has been corrected by a rotation of the spinal column. The authors have seen cases of slight scoliosis in young persons with a bilateral spondylolysis, having relaxed on one side, some of them could be reduced by simple dorsal decubitus. The deformity can be discovered by roentgenography of the patient in an upright position with a weight on his shoulders.

Rôle of Interlobar Fissures in Development of Tuberculosis—

Stephani and Kirsch state that interlobar fissures play an important part in the formation of tuberculous foci in the lung. Owing to the wide variety in the forms of fissures and the frequent existence of supernumerary fissures no region of the pulmonary parenchyma is far removed from a fissure. From a study of 2000 roentgenograms of the lungs often supplemented by transverse exposures the authors conclude that there are few apparently isolated foci (whether early infiltrations or small metastatic foci) which are not found to be juxtafissural when studied in anterior and transverse roentgenograms. For a focus to appear isolated in the parenchyma when it is actually juxtafissural it suffices that the segment of the fissure on which it is located is not contained in the plane of the ray that strikes it; this is evidently frequent. From the clinical standpoint interlobar propagation is important in the genesis of foci of consolidation of the parenchyma. This explains their sudden formation, their continuity and the fact that they invade from the start the whole of an apparently healthy lobe. Many parenchymatous foci develop rapidly because their formation is prepared by interlobar infection and roentgenograms taken at various angles will show that this mechanism is perhaps more frequent than is recognized.

- *Artificial Pneumothorax in Treatment of Pulmonary Echinococcosis G Scaglia—p 126
- Occlusion of Inferior Vena Cava. E Samek—p 170

Artificial Pneumothorax in Treatment of Pulmonary Echinococcosis—Scaglia states that the primary necessity in treating echinococcosis of the lung is to determine the site of the cysts in the respiratory parenchyma and to exclude from treatment the parapleural cysts which the pneumothorax might break into the pleural cavity at their point of least resistance. Positive endopleural pressure can give more rapid and permanent effects than negative pressure, it avoids the formation of pneumocysts and of suppurative complications, because it determines a rapid collapse of the residual sac and prevents the entrance of the respiratory air column and the germs that it conveys. The pneumothoracic hydatid sac resembles in its general traits the spontaneous sac. Partial pleural adhesions do not constitute an absolute contraindication, because they may be often overcome or they may allow the formation of an efficient pneumothorax. Artificial pneumothorax is inefficient if the membrane of the cysts is thickened, sclerotic and infiltrated with lime. If artificial pneumothorax is unsuccessful, surgical intervention must follow. The author does not believe that secondary bronchogenous echinococcosis of the lungs is capable of unfavorably influencing the application of the collapse therapy in pulmonary echinococcosis.

- Surgical Therapy in Tuberculosis of Female Genitalia L Soler—p 187
- Diagnosis and Surgical Therapy of Extramedullary Intradural Tumors J Goyanes—p 199

Technic for Determining Amount of Blood in Body—

Sanchez Perpina's original technic of determining volumetrically the total quantity of blood in the human body is as follows. One 5 cc and two 10 cc syringes are sterilized and dried. The 5 cc. syringe is filled with a 1 per cent solution of congo red to which 0.5 Gm of sodium salicylate has been added. With one of the other syringes 10 cc of blood is withdrawn from the vein of the patient's arm and the 5 cc of congo red solution is then injected through the same needle. The normal blood thus withdrawn is placed in a 10 cc test tube graduated in cubic centimeters. After five minutes, 10 cc of blood is withdrawn from the vein of the other arm with the remaining syringe. This blood is placed in a non graduated 10 cc test tube. The two test tubes are centrifuged for one hour and the quantity of corpuscles and serum in the test tube containing the normal blood noted. Then 0.25 cc of serum of the normal and of the dyed blood respectively are withdrawn with different pipets and placed in two different small tubes. These small tubes are of a spectral type. The closed end is a cylinder of 0.5 cc capacity graduated into hundredths of a cubic centimeter, and the open end is conical and has a capacity of 3 cc. To both serums a 25 per cent solution of uranium nitrate is added and then each tube is stirred with a different fine glass rod. Both tubes are centrifuged for fifteen minutes. A precipitate is formed in each tube. The negative difference in hundredths of a cubic centimeter between the precipitate in the dyed serum and that in the normal serum respectively, is the equivalent of the total amount of serum in the body. By previous experiments the author has determined that the negative difference between the height of the precipitate in the tube with dyed and normal serums represents the following equivalents: 0.02 cc is equivalent to 5000 cc of serum, 0.03 to 4500, 0.04 to 4000, 0.05 to 3500, 0.06 to 3000, 0.07 to 2500, 0.08 to 2000, 0.09 to 1500 and 0.10 to 1000. To determine the quantity of corpuscle in the whole blood the quantity of

corpuscles in the test tube of normal blood is taken as a basis and a proportion is made between the quantity of serum and corpuscles in 10 cc of normal blood and the quantity of total serum (already determined) and corpuscles (undetermined). For example, the 10 cc test tube of normal blood of a patient gave, after centrifugation, a volume of 6 cc of serum and 4 cc of corpuscles. In the second tubes there was a negative difference of 0.07 between the precipitate of the dyed serum and that of the normal serum. As this negative difference corresponds to 2,500 cc of serum the following proportion results: $6.4 : 2,500 :: 6.4 : 2,500, 1,666$. By adding the two large figures representing the total quantities of serum and of corpuscles, respectively, one obtains the number that indicates the total quantity of blood in the human body. For example in the case mentioned 2,500 cc of serum and 1,666 cc of corpuscles give a total amount of 4,166 cc of blood. This volumetric method possesses great precision and the author considers it better than the colorimetric methods used for the same purpose.

*Puncture and Electrocoagulation of Gasserian Ganglion. Kirschlner—p. 581

Inflammation—In an extensive article on inflammation contributed on the occasion of Werner Korte's eightieth birthday, Bier reviews the important landmarks in the history of knowledge of the subject. The author's special contribution to the subject is the application of hyperemia induced by hot air, constriction with elastic bandages or the use of a suction apparatus (Bier's hyperemia). The inflammatory reaction and the accompanying fever are favorable symptoms and are not to be combated. The successful treatment of the extremely painful gonorrheal joint by congestion hyperemia demonstrates the fallacy of the theory that the pain of inflammation is occasioned by hyperemia. The author advocates the use of various irritating agents, especially of foreign blood, to induce therapeutic fever and to stimulate the defense mechanism of the body. The gravest phlegmon can be closed after incision and cauterization with a hot iron. The acute inflammation and the fluids produced by the cautery produce an immunizing effect. Some of the minor practical applications of hyperemia treatment are the preservation of tendons in purulent tenosynovitis by making small incisions into the sheath and the use of a small incision in the treatment of suppurative inflammation of a lactating breast in combination with suction hyperemia. It has become evident that picking of the wound and frequent changes of dressings are injurious. In the treatment of gonorrheal and tuberculous joints, moderate motion has been substituted for total immobilization. The author stresses the value of blood transfusion. It is to be considered more than a replacement therapy, because it is capable of stimulating the hematopoietic as well as the defense mechanisms. For the latter purpose foreign blood is just as valuable. The author refers to the good results obtained by him in the treatment of patients with tuberculous, thyrotoxic and vascular disease with injections of small amounts of foreign blood.

Atypical Blunt Injuries of Knee Joint—Payr emphasizes the great importance of chronic traumatic synovitis as the result of a blunt injury. He is not concerned here with the "classic" types of injury, such as tears of the meniscus and of the crucial and lateral ligaments, and the splitting off of a piece of cartilage. The injuries under consideration are the bruising and tearing of the synovial lining, of the fibrous capsule and of the fat bodies of the joint. Effusion of blood and local necrosis are the immediate result. These cause irritation of the joint and spasm of the muscles. The latter leads to contracture of the quadriceps group or of the extensor group of muscles. The bruising of the lateral ligaments results, as a rule, in the contracture of the flexors, while injury to the posterior wall of the suprapatellar fat pad leads to a contracture of the extensors. The hypertrophic type of chronic synovitis leads to a shrinking of the fat pads but not unfrequently to a lipoma like proliferation, 'lipoma arborescens traumaticum,' characterized by locking of the joint. Too active use of the joint frequently leads to chronic effusion, but the dry shrinking form of synovitis is even worse. Filling of the joint with a solution of procaine hydrochloride epinephrine and flooding of the hypertonic muscles with a solution of procaine hydrochloride alone proved of value in the treatment. Addition of camphorated phenol is useful in some cases. Particularly good results were obtained with high voltage roentgen therapy as well as with short ray therapy. Careful exercise of muscles with interrupted current, massage, motion and movement of the patella are indicated. The cases that do not respond to treatment require surgical intervention. The author points out that the much favored removal of a meniscus will not cure the jamming by a fat pad, hygroma of the mucous membrane or tears of the extensor muscles. A search for the real offending cause must be made in the absence of typical lesions.

Gastrocardiac Syndrome in Phrenic Exeresis—Roemheld states that of 143 patients who underwent phrenic exeresis of the left side seventeen developed the characteristic gastrocardiac syndrome, manifested partly as gastric disturbances and partly as cardiac disorders (tachycardia, extrasystole or anginal pains). However these symptoms were only subjective and the chemical and roentgenologic examination of the stomach, as well as the electrocardiographic and roentgenologic examination of the heart remained negative, if a shifting of the heart toward the right or a turning in case of considerable elevation of the diaphragm are disregarded. The author agrees with Jahnke, who maintains that the symptoms are generally of a temporary nature. He points out that the comparatively low incidence of the gastrocardiac syndrome is probably due to the fact that most of the patients were of the asthenic type for the condition is found primarily and in its severest form in pyknic persons. Other factors that play a part in the pathogenesis of the gastrocardiac syndrome are neurasthenia and vasomotor irritability which become manifest in sweating, erythroderma and dermatographism. The author concludes from these observations that phrenic exeresis of the left side may be done without danger in asthenic persons with normal or culatory and digestive organs. However, caution is necessary in persons of the pyknic type or in patients having cardiac and gastric disturbances or a weak sympathetic nervous system. The physician should realize that in these cases exeresis on the left side may cause severe disturbances, and he should not resort to it unless other therapeutic measures, particularly pneumothorax, have failed.

Treatment of Tuberculosis with Iron-Copper-Chlorophyll Compound—Mattausch employed on oil soluble copper chlorophyll compound activated by small quantities of iron, administered in keratin capsules in the treatment of 218

patients with mild or average chronic pulmonary tuberculosis. Each capsule contains 0.1 mg of copper, 1 mg of iron and 18 mg of chlorophyll, all constituents being in the lipid-soluble form. The daily dosage is as a rule three capsules, one after each of the principal meals. This medication is continued for from ten to twelve weeks, interrupted for from eight to twelve weeks, and resumed again for from two to three months. In some cases a second and third period of medication may follow after the usual interruptions. A noticeable change in the reaction of the organism, that is, a reduction of the increased sensitivity and a change toward an increased resistance to a desensibilization, became noticeable in approximately 70 per cent of the cases after the first few weeks of treatment. This alteration is characterized by a decrease or cessation of the toxic processes, by a change from the neutrophilic to the lymphocytic tendency of the white blood picture usually by way of a monocytic intermediate phase, by a decrease in an eventually existing acceleration of the sedimentation speed of the erythrocytes, by a gradual disappearance of the increased metabolic rate and by an increase in the alkali reserve of the organism, when during the stage of increased irritability a shifting toward acidity has taken place. It may be expected that all these changes in reaction are accompanied by changes in the sympathetic nervous system, from the sympathicotonic to the parasympathicotonic. The patients feel better, new focal infiltrative processes begin to disappear, the erythrocyte and hemoglobin values increase, and the patients gain weight.

Tumor Destruction by Ultrashort Waves.—Reiter shows that the ultrashort waves capable of destroying tumors are those of wavelengths between 3 and 4 meters. Metabolic tests on tumor cells following exposure to ultrashort waves disclosed that the metabolism is inhibited. Comparative tests on tumors treated with roentgen rays revealed that enormous doses of roentgen rays are required to produce the effects given by ultrashort waves. The author thinks that the inhibition of the metabolic processes effected by the ultrashort waves is alone sufficient to explain the destructive action on tumor cells, but whether it is the only cause or whether the rays produce still other impairments cannot be decided on the basis of the studies carried on thus far. He expresses the opinion that the effects produced by the ultrashort waves hold promise that this therapy may prove helpful in the treatment of malignant tumors in human beings.

Paradoxical Gonadotherapy.—Klar points out that, since the researches of Puly, Laqueur, Petterson and others, the theory of the paradoxical gonadotherapy has been almost universally accepted. Starting from the fact that both hormones are present in the male and female organisms in different quantitative ratios, an attempt has been made to test the influence of these hormones in their reciprocal proportion. It was found that the female sex hormone exerts a noticeable influence on the appendages of the skin in both males and females. Whether this action of the female hormone is a direct one or whether it exerts its influence by stimulating the formation of a testicular hormone has not been proved as yet. The author reports the history of a man aged 28 who as the result of an endocrine disorder lost all hair of the head, beard, eyebrows, axilla and pubic region. It was decided to try treatment with oral hormone. Every second day the patient was given an injection of 1 cc (50 m. c. u.) of the hormone.

The treatment was continued for four and one-half weeks until a total of 17 cc of the hormone had been administered. After the fourth injection the beard started to grow. Hair appeared on the head a little later but, compared to the beard, it was rather scanty and of irregular, somewhat focal distribution. Simultaneously with the hair of the head, the eyebrows grew again. Their growth started on the external portion, but the hair of the median third had not yet appeared when hormone injections were discontinued. Axillar and pubic hair did not grow again. The author points out that this one case does not permit general conclusions.

Diagnosis and Treatment of Sterility in Women.—Haselhorst describes observations indicating that the uterus plays an important part in the transportation of spermatozoa and shows how disturbances in this function of the uterus may be a factor in sterility. He discusses the function of the uterine tubes and their disturbances and evaluates such conditions as genital infantilism and hypoplasia, nervous spastic symptoms, secretory disturbances and obstructions. He considers mechanical obstructions of the tubes one of the most frequent causes of sterility. He estimates the diagnostic value of the insufflation of the uterine tubes and of hysterosalpingography and, in discussing the treatment of mechanical obstructions, he points out that insufflation of the tubes may occasionally have some therapeutic value. He thinks that conservative methods should always be tried first and that only after these have failed should surgical interventions be resorted to. Implantation of the tubes gives better prospects for a subsequent pregnancy than does salpingostomy, for in the first case healthy portions of the tube are generally used whereas in the case of salpingostomy the oviducts are generally diseased. Observations have convinced the author that in general, surgical treatment of sterility is of little avail.

Technic of Sterilization in Men.—Boeminghaus describes a simple method of sterilization. By fixing the deferent duct subcutaneously, one can lay the spermatic cord free by a small incision into the scrotum (from 0.5 to 1 cm. in length). After that the spermatic cord can be drawn forward and a part of it may be resected or the peripheral end may be knotted. Each procedure interrupts the passage completely, whereas a simple ligation with silk thread does not guarantee the interruption. It is still more advisable to suture the peripheral stump into the skin while the central stump is allowed to slip back into the scrotum. The procedure is so simple that only from two to three minutes is required for each side. The author asserts that psychic alterations do not follow this form of sterilization.

Sequels of Icterus Neonatorum Gravis—Burghard and Schleussing call attention to the important literature on icterus neonatorum gravis, particularly to contributions describing a yellow discoloration of some regions of the brain, and they report a case of their own observation. The child died at the age of 5 months. The icterus had largely disappeared on the eleventh day of life, but after that there developed a somewhat "encephalic" symptomatology (opisthotonos, dulled senses, profuse perspiration, parkinsonism). The authors assumed changes in the region of the sympathetic centers particularly in the subthalamus, and the histologic changes found corroborated the symptoms to a considerable extent. They accept the theory expressed by other investigators that a bilious saturation of certain portions of the brain is the cause of these changes but whether the bilious saturation is preceded by other changes or whether the saturation itself represents the impairment cannot be decided. They conclude that only under exceptional circumstances and only when vital centers of the brain have been spared is there hope for recovery from icterus neonatorum gravis. They think that the fatal outcome is not to be deplored too much when it is considered that irreparable changes in the brain may be expected, which will make a normal development impossible and which after chronic sickness with paralysis and idiocy will finally end in death.

Hyperglobulia After Splenectomy in Hemolytic Icterus—Netonsek points out that hyperglobulia is a sequel of splenectomy has been known longest in pernicious anemia but that, because splenectomy is now rarely performed in these cases, the hyperglobulia that follows splenectomy has lost its importance in pernicious anemia and belongs now primarily to the splenogenic anemias. In hemolytic icterus the results of splenectomy are generally favorable, but hyperglobulia may follow the splenectomy. The author reports a case in which the first signs of hyperglobulia appeared six months after splenectomy. Medication with phenylhydrazine counteracted the hyperglobulia and changed it into a hemolytic anemia. The author points out that experiments have proved that hemolyzing toxins may also produce hyperglobulia.

Treatment of Amenorrhea with Ovarian Hormone—Kaufmann shows that in the absence of ovarian activity it is possible to produce a proliferation of the endometrium by the administration of the follicular hormone, and that if after this the hormone of the corpus luteum is given for a number of days the proliferated uterine mucous membrane is transformed into the secretory phase, so that menstruation sets in. It was found that the doses must be quite large in order to be effective. At first, women suffering from amenorrhea were given daily injections of 10,000 mouse units of the follicular hormone for three weeks, so that the total dosage for one menstruation was about 200,000 mouse units. Later it became possible to

administer 50,000 mouse units twice a week with a perfected preparation that allowed the organism to absorb the large quantities of hormones gradually. After the follicular hormone had been administered in sufficient quantities, the hormone of the corpus luteum was given for a period of five days. The total doses varied between 25 and 50 rabbit units. The author found that secondary amenorrhea can be counteracted some times with follicular hormone alone, but sometimes both hormones are required. He thinks that in these cases the ovaries are influenced by way of the hypophysis. In women having a hypoplastic uterus the follicular hormone alone often effects a considerable growth of underdeveloped genitalia. So far it has not been possible to counteract primary amenorrhea permanently in women having genital hypoplasia or normally developed genitalia. However, the fact that proliferation and secretion of the endometrium can be produced artificially justifies the hope that by prolonged treatment cooperation of the endocrine organs may be realized eventually.

Temporary Exclusion of Phrenic Nerve—Since phrenic exeresis is frequently followed by severe complications, particularly respiratory insufficiency, Naegeli and Heymer recommend temporary exclusion, in the course of which respiratory tests can be made. They induce the temporary exclusion by means of anesthetization with a 1 per cent solution of procaine hydrochloride. The result is paralysis of the respective half of the diaphragm for from three-fourths to two and one half hours. During this time the diaphragmatic action and position are observed by roentgenoscopy and the respiratory function is tested by the determination of the vital capacity with the dry spirometer and of the duration of the voluntary respiratory pause. If roentgenoscopy discloses a considerable elevation of the diaphragm and if the respiratory tests do not indicate too great a reduction of the respiratory function, it can be concluded with considerable certainty that exeresis will not involve dangers for the patient. However, if the respiratory values become considerably impaired during the temporary exclusion, complications must be expected and, if there is great impairment without considerable diaphragmatic elevation, phrenic exeresis involves great danger and is therefore contraindicated.

Determination of Indican in Blood—Schlierbach describes a new method for the quantitative determination of indican in the blood serum. The indican content is found with the aid of Pulfrich's step photometer, and the values thus detected may eventually be controlled by means of Lange's electric light colorimeter. The advantage of this test is that it does away with the use of photosensitive comparative solutions.

Paralysis Following Prophylactic Serum Injection—Demme reports one case of bilateral shoulder and arm paralysis following prophylactic injection of tetanus antitoxin, and a similar condition that developed after injection of diphtheria antitoxin. He calls attention to other reports in the literature. That paralytic manifestations have developed following injections of various serums militates against the assumption that the antitoxin as such is the injurious factor, and the author is inclined to agree with other investigators who assume that the paralytic manifestations are a form of anaphylactic reaction of the nervous system to the parenteral administration of heterogenous serums. This theory is also borne out by the fact that the neuritic manifestations are nearly always preceded by a typical serum exanthem. It is surprising that independent of the site of the serum injection (in the reported case in the buttock) the paralysis usually involves the region of the brachial plexus and the muscles of the shoulders and arms.

Whether this is due to a particular affinity or to other factors has not been determined as yet. The prognosis of the paralytic symptoms is favorable, for they gradually disappear again. The author emphasizes that these comparatively rare complications are no contraindication to serotherapy.

New Rapid Pregnancy Reaction—Brühl and Hollstein employed the rapid pregnancy reaction of Hirsh-Hoffmann on the urines of sixty-nine women forty-seven of whom were pregnant. The test failed in only two cases, in which the test animals were too old and large (30 Gm). The authors use virgin mice that are at the beginning of sexual maturity and weigh from 12 to 15 Gm. At least two animals should be used for each test. The urine is injected in three doses of 12 cc each (in the course of twenty-four hours) under the skin of the back. After forty hours the animals are killed, and the ovaries are embedded and sectioned. If the first injection of urine is made in the afternoon, the test is completed in the morning of the second succeeding day. A positive reaction is characterized by the following microscopic changes: (1) follicle cysts with beginning luteinization, (2) corpus luteum cysts, (3) luteinization of the theca of the atretic follicles and of the interstitial tissues, and (4) blood dots in larger numbers.

Indications of Dangers to Fetal Life—Mayer discusses two of the signs which indicate that the life of the fetus is in danger: the retardation of the fetal heart tones and the discharge of meconium. According to Sachs, a living child cannot be expected when retardation to a frequency of less than 100 persists for more than forty minutes. The author concedes that this may be true generally but cites a case in which retardation of the fetal heart tones persisted for several hours and a viable infant was finally delivered. He discusses the various factors that may lead to retardation of the fetal heart tones, particularly cerebral pressure and intracranial hemorrhage. In case of increased cerebral pressure he considers the use of the forceps advisable only when it hastens and facilitates delivery. If the use of the forceps requires considerable time and pressure it may even increase the danger. The author states that most practitioners consider the discharge of meconium a sign of danger and, as a result, often resort prematurely to the use of the forceps. He asserts that greenish amniotic fluid with fine floccules is occasionally observed at the beginning of labor and a viable infant is delivered several hours later. He thinks that the discharge of meconium in the form of a discoloration of the amniotic fluid is by itself of relatively slight importance. It is more dangerous when it concurs with a disturbance of the heart tones or with an infection of the uterus. It cannot be denied that the discharge of fresh clots of meconium is a rather grave sign but it is difficult to differentiate between freshly discharged meconium and the meconium of gestation because it is impossible to say how rapidly the amniotic fluid dissolves the meconium and the absence of clots does not necessarily exclude the fresh discharge of meconium. At any rate the author agrees with Seitz who maintains that the discharge of meconium alone is no indication for an operative intervention. He reaches the conclusion that it may be extremely difficult to recognize when the life of the fetus is in danger. He thinks that the danger is generally overestimated and that delivery by forceps is done too often. The result is a higher percentage of dead infants and dead children.

Helminthiasis and Gynecologic Disorders—Mahler thinks that infestation with intestinal parasites is not given the necessary consideration in gynecologic disorders. He points out that intestinal parasites may cause such disorders as salpingitis, appendicitis, pelviperitonitis, cholecystitis, abscess of the liver, diffuse peritonitis and necrosis of the pancreas. The behavior of *Ascaris*, *Trichocephalus* and *Oxyuris* makes it understandable that they may lead to such manifestations. Complications following obstetric or gynecologic operations also may be caused by helminths, particularly by *ascarides*. Nervous symptoms may be caused by helminths, and clubbed fingers, articular swellings and edemas have been observed. The author thinks it probable that some intestinal parasites produce toxins that influence the blood and the nervous system. Moreover, helminthic toxins may act on the endocrine system and thus may involve the gynecologic sphere. The diagnosis of helminthiasis can be based only on the examination of the stools. Eosinophilia cannot always be relied on. The author thinks that helminths should be searched for in refractory abdominal symptoms, for he is convinced that their detection and removal will bring relief in many such cases.

Anemias in Cirrhosis of Liver—Fellinger and Klima studied the hemograms, particularly the behavior of the erythrocytes, in forty-eight patients having cirrhosis of the liver. They found that fourteen patients had a normal or an almost normal hemogram. Anemia was present in thirty patients (twelve had a subnormal and eighteen a supernormal color index). Four patients had polglobulism. The high incidence of anemia in patients having cirrhosis of the liver becomes still more evident when incipient cirrhosis is excluded and only completely developed cirrhosis is taken into consideration, for of the fourteen patients presenting a normal hemogram eleven had incipient cirrhosis. Thus it may be said that anemia is almost typical in fully developed cirrhosis and that its appearance is practically independent of eventual hemorrhages. Anemia with increased color index predominates, particularly in completely developed cases of cirrhosis, while a normal or reduced color index is generally found in the incipient stages. Moreover, it has been observed that a slight anemia with normal or subnormal color index in the beginning of the cirrhosis became more severe during its later development and that the color index increased. The morphology and the size of the erythrocytes likewise change, and these changes frequently resemble those that occur in pernicious anemia. The leukocytic hemogram shows a slight leukopenia, particularly in uncomplicated cirrhosis. The author discusses the causal connections between cirrhosis and anemia.

Differential Diagnosis of Aneurysm of Long Saphenous Vein and of Femoral Hernia—Patel observed three patients presenting an aneurysm of the long saphenous vein in the oval fossa. In all three the condition had been diagnosed elsewhere as femoral hernia. The author points out that Gubral, who studied this problem carefully, came to the conclusion that approximately 50 per cent of the cases of aneurysm of the long saphenous vein in the region of the oval fossa are erroneously diagnosed as femoral hernia. Gubral described the following differentiating symptoms: When the tumor of the oval fossa is pressed lightly and at the same time the abdominal muscular pressure is exerted in several jerks, a humming sound is heard produced by the clashing of the fluid in the

vessel, if an aneurysmal varix exists. This phenomenon is absent in case of femoral hernia. The author resorted to this test in the three cases that came under his observation, it enabled him to diagnose all three as aneurysmal varix, and the operation corroborated the diagnosis.

Lymphangiocystofibromia of Uterus. A. Muschik—p. 2389
Historical Reporting in Gynecology. J. Stur—p. 2397

Hyperemesis and Hypochloremia—Kretzschmar points out that disorders accompanied by frequent attacks of vomiting often lead to hypochloremia and that enteral or parenteral administration of sodium chloride is often helpful in the treatment of these conditions. He reports a case in which a woman who developed hyperemesis gravidarum lost weight rapidly and developed icterus and fever, her pulse rate increased and periods of apathy alternated with periods of excitation. Treatment with insulin and dextrose was ineffective and the discovery of hypochloremia induced the author to administer sodium chloride. From 2 to 3 per cent of sodium chloride was added to the 10 per cent solution of dextrose administered by rectum and a 20 per cent solution of sodium chloride was given intravenously. This treatment was soon followed by considerable improvement and interruption of pregnancy was avoided.

Agranulocytosis-Like Disorder During Puerperium—Heim calls attention to malignant ulcerations of the neck of the uterus which are not of venereal or tuberculous origin. Hematologic studies reveal a connection with severe functional disturbances of the hemopoietic system. After reviewing several cases from the literature, the author reports a case that he observed. It is particularly noteworthy because the woman was in the puerperal stage. Following delivery there was an elevation of temperature. Four days later the patient had difficulty in swallowing. The throat was red and the tonsils were enlarged but not coated. In the left posterior portion of the edematous vagina a discolored painful ulceration was detected. Nosebleed and chills set in. Several days later an aphthous stomatitis had developed on the pharyngeal ring. The tongue was sore and a vesicular eruption appeared along its edge. The gums were swollen and presented ulcerations and partial necroses. A pemphigus-like exanthem appeared on the skin. Examination of the blood disclosed 1,290,000 erythrocytes, 25 per cent of hemoglobin, a color index of 1.2400, leukocytes and the absence of blood platelets. The granulocytes and monocytes showed signs of degeneration. A blood transfusion was given and the condition of the blood improved slightly, but a few days later she died. The author points out that a true agranulocytosis did not exist in this case, because both white and red blood pictures were greatly impaired. In hematology these forms have been referred to as symptomatic agranulocytosis, hemorrhagic aleukemia or pannyelophthisis. The latter can be excluded in the reported case, since it could be demonstrated that the hemopoietic function of the bone marrow was largely preserved. The author thinks that an anemia already existed during pregnancy, although the amniocentesis did not reveal it. He considers the prognosis of cases of this type unfavorable.

Myoma Praevium and Placenta Praevia—Ottow relates the history of a woman, aged 37, who was brought to the clinic on account of hemorrhages in the late stage of pregnancy. On examination it appeared that the pregnancy was at term with transverse presentation and placenta praevia. After a few days of rest in bed the hemorrhages ceased and the woman left the clinic but was readmitted two weeks later when the hemorrhages recurred and slight labor pains set in. On the basis of the diagnosis and because the woman desired a living child at all costs, cesarean section was resorted to and a living child was delivered. A myoma, the size of a child's head, was found on the anterior uterine wall in the region of the isthmus. The myoma was partly loosened from its bed and the placenta was

attached to the capsule of the myoma. One part of the placenta reached into the region, which on account of the interposition of the myoma appeared to be the internal orifice of the uterus. The author shows why a conservative procedure, that is, enucleation of the myoma, was not advisable in this case. A supravaginal amputation was performed, but the right ovary was preserved. Two weeks later, the woman and child were discharged from the hospital. The author describes the probable development of the myoma and the insertion of the placenta on it. He is unable to state definitely whether the hemorrhages were caused by the placenta praevia, by the myoma or by both. He explains when enucleation of the myoma is advisable and when total extirpation of the uterus is preferable.

*Spontaneous Pneumothorax in Apparently Well Persons. T. H. Larsen—p. 1130

*Significance of Secondary Infection as Cause of General Infection in Acute and Chronic Gonorrhea. E. Bruusgaard and N. Danbolt—p. 1143

Malignant Tumors in Long Bones—Of the seventeen cases of primary sarcoma treated by Roscher, seven were localized in the humerus. In one of these interscapulothoracic exarticulation was done, in six resection with transplantation of fibula. In one case with extensive periosteal sarcoma in which resection was done, followed by roentgen after treatment, the patient was able to work for thirteen years after the operation. The author concludes that resection is contraindicated when examination or operation reveals infiltration of the soft parts in which case interscapulothoracic exarticulation should be performed immediately. Roentgen after treatment should follow every resection. There were eight cases of primary sarcoma of the femur, out of seven in which amputation was done five have been free from recurrence for from five to nineteen years. There were also one case of primary sarcoma of the tibia and one of the fibula, the former was considered inoperable because of glandular metastases, and in the latter Gritti's amputation was followed by fatal metastases. The author states that radical amputation or exarticulation, at all events in primary sarcoma of the femur, saves life in a number of cases while the results of resection are rarely good. Patients preferred resection to amputation or exarticulation, but the greater risk of resection must be more clearly stressed. The material encourages active treatment of bone sarcoma at the earliest possible stage of the disease. There were five cases of metastatic bone tumors, in such cases operative treatment may occasionally be palliative.

Spontaneous Pneumothorax in Apparently Well Persons—Of Larsen's seven patients, three recovered in a short time, the fourth in six months and the fifth after more than a year. In the sixth the pneumothorax persists after two years and in the seventh there is a partial pneumothorax in the apical region after one and one-fourth years. The fourth and fifth patients were brothers. In the fifth, formation of exudate occurred after a year and led to resorption of air, there was no fever and the Pirquet reaction was negative. Aspiration of air was tried in two cases, without effect.

Secondary Infection as Cause of General Infection in Acute and Chronic Gonorrhea—In Bruusgaard and Danbolt's three cases of chronic gonorrhea with prostatitis a secondary pyemic infection leading to general infection dominated the picture. In two cases, yellow hemolytic staphylococci were demonstrated by blood cultures, in the third, hemolytic streptococci. The first case was fatal after a week from almost fulminating pyemia, in the second, amputation of the femur was indicated because of alarming arterial hemorrhages, the third patient recovered after a subfebrile period of several months. The cases are seen to illustrate the gravity of gonorrhea not only because of the grave complications due to the gonorrhea but because of the secondary infections and mixed infections which accompany it or for which it paves the way.

THE SURGICAL TREATMENT OF INTRACTABLE PAIN

LOYAL DAVIS, M.D.
CHICAGO

The suffering associated with syphilitic visceral crises, inoperable carcinomas with metastases, angina pectoris, and trigeminal neuralgia needs only to be mentioned to emphasize that there are many unsolved problems associated with the physiology of pain and the surgical procedures employed for its relief. Certain clinical and experimental observations are of interest in an attempt to learn more of the pathways for the conduction of painful impulses and the methods employed for their surgical relief. In many instances, surgical empiricism has preceded known anatomic and physiologic facts in attempts to relieve the pain of some of these diseases.

Some years ago, Ranson and his associates¹ found in the cat that, as the posterior spinal roots enter the spinal cord, there is a sharp separation of the larger myelinated from the finest myelinated and unmyelinated fibers. The latter fibers, which constitute the lateral division of the root, are so placed that they may be divided easily by making a small incision along the posterior lateral sulcus of the spinal cord. They found that, immediately before such a lesion was made stimulation of the posterior root caused struggling, a rise in blood pressure and rapid respirations. After section of this lateral division, without injuring the large medial division of the root, none of these responses existed. On the contrary, section of the large medial division of myelinated fibers produced no effect on these evidences of pain. Likewise, it was found that section of the lateral columns of the white matter of the cord prevented these somatic painful reflexes.

It became of interest to know whether or not painful impulses from the viscera traveled over the same pathways within the spinal cord. Consequently visomotor, respiratory and other evidences of pain in an animal were produced by faradic stimulation of the thoracic-sympathetic trunk.² Varying rates of stimulation of the distal end of the splanchnic nerves invariably produced painful responses in normal animals. Subsequently, various horizontal lesions were produced in the spinal cord in an effort to obliterate these responses.

Sections of the posterior, anterior and lateral columns and lateral and posterior hemisections were produced without effect. It was found that a complete transverse section of the cord was the only experimental lesion that was followed by a cessation of these painful responses to stimulation. It was concluded that painful impulses from the viscera, transmitted by the thoracic-sympathetic trunk, are conducted upward by relays of short spinal paths with synapses in the gray matter of the spinal cord and do not pass into the lateral spinothalamic fiber tracts in the white matter, which serve to transmit somatic painful impulses.

An effort was then made to perform experiments which would more closely simulate visceral pain clinically. Dilation of the cystic and common ducts and of the ureters by balloons was undertaken. In the meantime, Schrage and Ivy,³ working on the same problem from a different angle, showed that dilation of the cystic duct in the dog is accompanied by a marked inhibition of respiration, vomiting, struggling and other evidences of pain. They showed also that these responses could be abolished completely by section of the right splanchnic nerve and that they were unaffected by division of the vagi or left splanchnic nerves. In association with Hart and Crain,⁴ these experiments were repeated, and, in addition, lesions of the spinal cord were produced in a manner similar to the earlier experiments. The results obtained were identical, that is, a complete transverse section of the spinal cord, or a lateral lesion which definitely injured the gray matter was necessary to obliterate the responses to these painful impulses. The posterior spinal roots were sectioned in a series of these animals and it was found that, if a sufficiently large number were sectioned bilaterally, painful responses so produced could be abolished. Stone has recently corroborated these experiments on dilation of the gallbladder after posterior root section. He has also conducted a series of similar experiments with dilation of the gallbladder after anterior root section. Contrary to the views expressed by Lehmann,⁵ Shaw⁶ and others that there is an antidromic fiber in the anterior roots which serves as a conduction pathway for visceral painful impulses, Stone has been unable to obliterate the normal responses from dilation of the gallbladder by section of the anterior roots.

Thus far then it may be suggested that visceral afferent impulses from the gallbladder for example,

pass upward through the right splanchnic nerve, the thoracic sympathetic trunk, by way of the white rami to the spinal nerves, and then by way of the posterior roots into the cord. Within the cord these impulses pass upward by relays of short spinal paths with synapses in the gray matter.

These experimental facts have a definite and direct application in clinical surgery. For many years, surgeons have attempted to relieve the pain of the visceral crises in tabes dorsalis by posterior root sections or by

spread along the ulnar sides of both arms, but more particularly into the left, in which the pain was felt in his ring and fifth fingers. A laminectomy was performed, and the posterior roots of the first six thoracic segments were sectioned bilaterally. His relief from pain has been complete for one year following the operation without the slightest impairment of function in his upper extremities (fig 2).

As far as I am aware, this is the first recorded instance of the relief of angina pectoris by posterior root section. Such a surgical procedure for the relief of angina pectoris is based on a knowledge of the pathway of the visceral afferent impulses into the spinal cord. It should be recognized also that the cardiac accelerator mechanism is not disturbed by such an operation.

This leads to the mechanism of the reference and recognition of pain from visceral disease in the periphery. A number of theories exist for the explanation of the sensation evoked by visceral stimulation. Lennander's¹⁰ idea that all visceral pain was mediated through the parietal peritoneum was disproved by Neumann.¹¹ Ross¹² has stated that either true visceral pain may be present alone or it may occur in association with pain in the skin, muscles and connective tissue innervated by the same spinal segments. Lange¹³ thought all pain in visceral disease was purely reflex in origin. He traced the impulses through the afferent fibers of the vegetative nervous system to the spinal

Fig 1—Thoracic segment of the spinal cord. a direction of the incision anterior to the dentate ligament to include the anterolateral column for the relief of somatic pain; this incision must be carried medially (b) to include part of the gray matter in order to obtain relief from visceral pain.

anterolateral sections of the spinal cord, an operation which was first suggested by Spiller and carried out by Martin.⁸ The results of chordotomy operations performed for the relief of such visceral pains uniformly have been unsuccessful if the sections have been made to affect only the spinothalamic tracts. Whereas such a procedure invariably relieves pain of somatic origin, visceral pain has been unrelieved. However, it has been noted that when such lesions have been carried deeply, so that a portion of the gray matter has been included, relief from tabetic visceral crises has been obtained (fig 1). Recently Foerster,⁹ in an autopsy specimen, demonstrated the level of a chordotomy that had been performed with success for the relief of gastric crises. His sections showed unmistakably the extent of the lesion in the gray matter of the cord. This is exactly what one would expect from the experimental facts.

The results of posterior root sections for the relief of visceral crises have not been uniformly successful. Probably the error has been in the failure to section a sufficient number of posterior roots bilaterally. A clinical experience with such a case is to the point.

The posterior roots from the fourth dorsal to the twelfth dorsal segment inclusive were sectioned bilaterally in a patient with severe visceral crises. This procedure was carried out in two operations and inadvertently the eighth pair of spinal roots were left intact. Although the area of superficial cutaneous sensibility represented by this root was extremely small, the patient continued to have pain until this root was sectioned. It would appear that only a very small pathway into the spinal cord was sufficient to carry the painful visceral impulses in this patient.

In support of the effect of adequate posterior root sections on the relief of pain of visceral origin, another clinical experience is in point.

A man had been suffering from angina pectoris for the past four years, during which time he had been wholly unable to work. He had been under observation in the cardiac clinic and was taking large doses of glyceryl trinitrate daily for the relief of his pain, which occurred while at rest and on the slightest exertion. His pain began over the sternum and

Fig 2—Sensory loss after bilateral section of the posterior roots of the first six thoracic segments for the relief of angina pectoris.

cord, where he believed that radiation occurred along the sensory tracts to the abdominal wall. Spiegel¹⁴ states that the impulses pass to the posterior horns of the spinal cord and are there diffused to the roots of the corresponding somatic nerves. Mackenzie,¹⁵ Ross¹

and Head¹⁶ all believe that in visceral disease a form of irritation is produced in the spinal cord and that sensory impulses from other parts passing into this segment are so exaggerated as to be painful.

In corroboration of the work of Weiss and Davis¹⁷ and of Lemaire,¹⁸ we have been able to relieve the pain of gallbladder colic, angina pectoris and other intra-abdominal lesions by the subcutaneous infiltration of procaine hydrochloride solution in the peripheral area to which the pain is referred. In experimental support of these clinical observations, we¹⁹ have shown that the evidences of pain produced in an animal by dilation of the cystic duct are definitely altered by section of the intercostal nerves. The relief of the pain of angina pectoris by paravertebral injections of alcohol is corroborative of these facts. I suggest, however, that this relief is obtained by the effect of the alcohol on the intercostal peripheral nerves and not solely on the injection of the sympathetic rami communicantes. The anatomic relations of these structures make isolated injections of the rami communicantes almost impossible, and the presence of peripheral cutaneous sensory changes make this supposition highly probable. It is possible that visceral painful impulses produce efferent cutaneous reflex effects, which in turn liberate a metabolite in the skin which is painful. These somatic painful impulses are in turn carried into the cord and to consciousness over the well known somatic afferent pathways. This conception of the mechanism of referred pain from the viscera was set forth by Pollock and me²⁰ as the result of a series of experiments on stimulation of the cervical sympathetic chain before we were aware of Lemaire's work and his similar theory.

Recently, the role of the sympathetic nervous system in the production of pain has been under investigation. The results of some of these experiments have led some authors to doubt the validity of the Bell-Magendie law, which attributed motor functions alone to the anterior spinal roots. Special emphasis on the importance of this aspect of the sympathetic system has been made by the reports of the relief of other types of pain such as angina pectoris, causalgia and abdominal pains by various surgical operations on the sympathetic nervous system. Jonnesco²¹ has relieved the pain of angina pectoris by the removal of the middle, inferior cervical and first thoracic ganglions of the left sympathetic chain. Successful results have been reported from essentially similar operations by Bruning²² and others. Coffey and Brown²³ have obtained somewhat similar results by sectioning the sympathetic trunk and the superior cardiac nerve below the superior cervical ganglion or by excising this ganglion. Foerster, Alten-

burger and Kroll²⁴ reported some observations on man in which pain was produced by suitable stimuli in areas in which the somatic afferent supply had been severed. They believed that the only possible intact afferent pathway consisted of periarterial plexuses of nerve fibers which ended in the sympathetic ganglionic chain. From these observations, they concluded that sensory impulses may travel along periarterial plexuses to the sympathetic ganglionic chain and from there enter the spinal cord. On the basis of the work of Mandl²⁵ on paravertebral injections, attempts have been made to block the rami communicantes by such a method.²⁶ Abdominal pains have likewise been relieved by von Giza,²⁷ Scrimger²⁸ and Archibald²⁹ by section of the abdominal sympathetic nerves, and the sacral portion of the sympathetic trunk has been resected for the relief of pain in inoperable carcinoma of the uterus.

Although pain may be produced by stimulation of parts of the sympathetic nervous system or relieved by severance of suitable parts of the sympathetic nervous system, there is no agreement as to the physiologic mechanism involved. Painful impulses may be conducted along the sympathetic nerve fibers, or the visceromotor or other reflex activities may produce conditions which in turn are responsible for conscious pain. On the other hand, both mechanisms may be present.

Pain has been produced by faradic stimulation of the superior cervical sympathetic ganglion in man by Frazier,³⁰ Peet³¹ and Foerster.³² The head is a particularly suitable part of the body for the investigation of the role of the sympathetic nervous system in the production of pain, because it is possible to cut all the posterior roots connected with the cervical sympathetic chain without producing an analgesia of the skin overlying the parts from which painful sensation may occur. Since it is conceivable that the superior cervical ganglion and its immediate environs are supplied with sensation by nervi nervorum, it is necessary to clear this area of afferent nerves when one wishes to study the results of faradic stimulation of the ganglion.

Langley³³ presented evidence to show that there are no afferent fibers in the cervical sympathetic trunk; this has been strengthened by the work of Ranson and Billingsley.³⁴ On an anatomic basis the sympathetic supply to the structures of the head and face must be considered as consisting purely of efferent fibers.

In a series of experiments to determine the role of the sympathetic fibers in the production of pain in

the face, Pollock and I²⁰ found that (1) stimulation of the cervical sympathetic trunk does not produce pain, and (2) that stimulation of the superior cervical sympathetic ganglion produces pain. The latter fact holds true after section of a large number of anterior and posterior spinal roots, beginning with the first cervical segment. It is also true after section of the anterior spinal roots and section of the sensory root of the trigeminal nerve. Pain could not be produced, however, by stimulation of the isolated ganglion after section of the posterior spinal roots and the sensory root of the trigeminal nerve. It is probable, therefore, that stimulation of the superior cervical sympathetic ganglion produces an effect which is carried by way of post-ganglionic efferent fibers to the structures innervated by the sympathetic fibers. These efferent impulses produce an effect on the skin and other structures the exact nature of which is as yet unknown. It is quite possible that this effect is linked with the sympathetic innervation of the blood vessels and that a metabolite is liber-

observations (1) that all sensation did not disappear from an expected area following section of the posterior roots, (2) that pain was not relieved or returned after section of the posterior roots, and (3) that pain did disappear permanently after section of the anterior and posterior roots.

A clinical experience may be cited in which there was a complete loss of all sensibility after section of all the posterior roots to an upper extremity in a man.

A young man suffering from the sequelae of epidemic encephalitis in the form of a parkinsonian state applied for help. The rigidity was so great as to make life unbearable. Despite the administration of large and sustained doses of scopolamine, he was often unable to assist himself in the simplest wants. It was thought justifiable to section the posterior roots which supplied the right upper extremity, which was the more rigid in the hope that, if the rigidity disappeared subsequent muscle reeducation would make the limb serviceable.

Dec. 14, 1928, under local anesthesia, a laminectomy was performed, on the third, fourth, fifth and sixth cervical vertebrae. The fourth, fifth, six, seventh and eighth cervical posterior roots on the right side were ligated and sectioned. The sensory loss occupied chiefly the areas ordinarily attributed to the fifth, sixth and part of the seventh cervical segments (fig. 3). Therefore, Jan. 9, 1929, again under local anesthesia, a laminectomy was performed on the seventh cervical and on the first, second and third dorsal vertebrae. The first, second, third and fourth right dorsal posterior roots were sectioned. Sensory examination at this time showed complete loss of pain, touch and temperature sense over the entire right upper extremity and the upper part of the thoracic wall extending downward to the nipple line. The area of loss of touch slightly exceeded this border, and the loss of cold was slightly more extensive than the loss of touch. Passive movement of the segments about the joints of the fingers, wrist and elbow were not recognized. Vibration sense was absent over the elbow, wrist, fingers and thumb, and he was unable to describe the position passively imposed on the extremity. Deep pin prick and piercing the skin were not felt on the forearm, lower part of the arm, wrist or fingers. Pinching with artery forceps did not produce pain, and piercing the median basilic vein, scratching its intima and lacerating it produced no pain. No sensation was experienced on the prolonged application of the distended cuff of a sphygmomanometer, and its release was not accompanied by any sensation. Compressing a segment of a vein and distending it with physiologic solution of sodium chloride produced no pain. Piercing the radial artery, distending a segment of it with saline solution and lacerating it produced no sensation. The upper border of the loss of deep sensation and pressure pain was not outlined at this time.

April 7, 1930, the patient was reexamined. The upper level of pressure sensation was bounded by a line 1½ inches below the area of loss of touch. The loss of deep pressure pain sense, with a 6 Kg. stimulus, was bounded by a line about 2 inches below the area of loss of touch. It is of interest that deep pressure pain could not be elicited over the upper part of the chest because the supply to the pectoral, serratus magnus and latissimus dorsi muscles had been interrupted. The most severe twisting and pinching of the skin was not felt and transfixing the skin with a hypodermic needle did not evoke any sensation. About 1 cc. of a solution of neoarsphenamine was injected about the median cephalic vein and, although inflammatory changes were produced, no sensation was felt. The radial artery was transfixed by a needle electrode, and no sensation was felt on stimulation by a strong faradic current.

These observations have been corroborated by experimental investigations of the reflexes on animals before and after decerebration. The insensitive extremity participated in the rigidity assumed by the other legs. It reacted normally to tonic neck and labyrinthine reflexes.

FIG. 3.—Sensory loss after section of the fourth, fifth, sixth, seventh and eighth cervical posterior roots.

ated which in turn stimulates the ordinary sensory nerve endings of the fifth nerve. This impulse is then transmitted centrally and is recognized as pain. The relief of pain of visceral disease by blocking or severing the intercostal and abdominal nerves, which has been previously mentioned, is in direct relation to these observations.

Finally, the peripheral pathway for painful sensations must be considered. In other words, may pain be conducted antidromically over the anterior spinal roots into the spinal cord? This theory, in contradiction of the Bell-Magendie law, has been invoked to explain the failure of posterior root sections to relieve somatic pain.²¹ Such a conception, if correct, would have considerable bearing on the surgical relief of pain. Without reciting the details of the clinical cases reported in the literature, the assumption of the existence of antidromic sensory fibers in the anterior roots was based on the

35 Kidd, Leonard. Afferent Sensory Fibers in the Spinal Ventral Roots. *Brit. M. J.* 2: 359, 1911. Lehmann, Shawe, Wartenberg. R. Klinischen Studien zur Frage der Geltung des Bell-Magendieschen Gesetzes. *Ztschr. f. d. ges. Neurol. u. Psychiat.* 123: 518, 1928.

36 Davis, Loyal, and Pollock, L. J. The Peripheral Pathway for Painful Sensations. *Arch. Neurol. & Psychiat.* 24: 883 (Nov.) 1930.

Crossed extension was produced in it by flexor responses to painful stimuli applied to the opposite upper extremity. Not a single reflex movement on the same or opposite side could be elicited by any form of stimulation of the affected extremity. Pricking the skin, pushing against the foot pad, incising the skin or aponeurosis, fascia, muscle or nerves, stimulating the vessels and nerves with a faradic current, scraping the periosteum and crushing the bones all failed to produce the slightest motor response. I believe it is justifiable to assume that, if all of the posterior roots to an extremity are sectioned, all sensation, cutaneous and deep, will be lost.

SUMMARY

1 Visceral afferent painful impulses travel by way of the splanchnic nerves to the spinal cord and thence upward by relays of short neurones in the gray matter.

2 Chordotomy, unless the lesion is deep and injures the gray matter, will not relieve visceral pain, although it will abolish intractable somatic pain.

3 Posterior root section operations, in which a sufficiently large number of roots are severed, will abolish visceral pain.

4 The pain of angina pectoris has been abolished by posterior root section. Such an operation definitely attacks the afferent pathway for the painful impulses and does not interfere with the cardiac accelerator mechanism.

5 The stimulation of efferent sympathetic fibers produces changes in the periphery, which in turn stimulate the ordinary somatic afferent fibers that transmit pain. The relief of pain by section of sympathetic fibers is, therefore, based on the interruption of efferent pathways.

6 Section of all the posterior roots that supply the upper extremity in man and in animals interrupts all form of superficial or deep sensation.

7 There is no evidence of a sensory pathway through the anterior spinal roots.

54 East Erie Street

ABSTRACT OF DISCUSSION

DR. MAX M. PEET, Ann Arbor, Mich. A good deal of confusion has arisen as to what is meant by sympathetic fibers and as to whether they carry pain or are purely efferent or afferent. The anatomists Ransom and Hubert probably take the best view. They state that surgeons are confusing the matter when they speak of surgery of the sympathetic system instead of surgery of the autonomic system. According to them the sympathetic system is a gross anatomic term connoting a gross group of nerves and ganglions which are of mixed nature, they contain efferent autonomic fibers and posterior root sensory fibers. When as surgeons we speak of stopping pain by a sympathectomy do we mean that we are cutting posterior root fibers or that we are interrupting efferent fibers carrying impulses out from the cord? Are we stopping pain because we are stopping it or are we stopping its recognition? I have felt that the autonomic system may cause pain by causing peripheral contracture of the blood vessels or by some other unknown mechanism and that when we cut the gross anatomic structure spoken of as a sympathetic chain we may be doing one of two things either cutting autonomic fibers that are carrying out impulses or cutting sensory fibers returning that sensation in which case we are interrupting the recognition of the original stimulus. The question has been raised by Davis and others. Do the anterior roots carry pain sensation or anything that may cause pain sensation? I have had only one indication that a sensory fiber may be carried in the anterior root. This was in an elderly woman who had special intercostal neuralgia every way resembling that of intercostal neuralgia

except in its anatomic distribution. It is the only case that I have seen that I would want to call intercostal neuralgia. She had every manifestation of a tic douloureux except it was in her back. The pain was completely eliminated and no longer would any stimulus bring on pain, but at times she had pain develop without outside stimuli. Some time later I exposed the spinal cord again, and when I touched one of the anterior roots she had excruciating pain which she described as identical with the pain she had been having, and when I cut them she was free. I am convinced from a series of a little over eighty chordotomies that chordotomy performed at a deep enough level and sufficiently high in the spinal cord will relieve both somatic and visceral pain. I feel that the visceral pain enters at many levels, that it is carried up along that gross sympathetic tract and that one must go very deep into the gray matter, as Davis has shown, in order to stop the pain of visceral origin.

DR. JOHN L. GARVEY, Milwaukee. Dr. Davis has presented some very conclusive clinical experiments. It is very difficult to go into the subject of the sensation of pain in animal experimentation. I think it has been carried through in a clinical way by the neurosurgeons in a fine manner and that they have added a great deal to the knowledge of neural physiology.

THE POSTPARTUM KIDNEY

HENRY W. E. WALTHER, M.D.

AND

ROBERT M. WILLOUGHBY, M.D.

NEW ORLEANS

Renal infections complicating pregnancy are receiving an ever increasing degree of attention from both obstetricians and urologists. This unquestionably bespeaks a further reduction in the untoward situations arising out of the parturient state. Until recently, the major portion of care was devoted to the antepartum period, to the neglect of many postpartum sequelae. It can no longer be taken for granted that, following delivery, vigilance can be relaxed. Hospital records attest the fact that postpartum complications still occur and, in fair measure, the urinary tract shares in these unfortunate end results.

Because such cases have come under our observation, in private practice, it was considered that a report might be of interest. We include cases that were unrecognized prior to delivery, cases recognized before delivery but remaining untreated until after parturition, and cases recognized but presenting no complications until after childbirth.

The delay in detecting many of these conditions we believe due to the patient's feeling that such symptoms are a part of the discomfort pregnant women must endure, while others purposely conceal their distress in fear that complaint will render them subject to additional suffering by having to undergo instrumental investigation. It would appear, therefore, that the physician must encourage more assiduous urine studies and offer assurance that today cystoscopy can be performed painlessly.

Before entering into a discussion of the group of cases to be considered, it might be well to review briefly the theories that have been advanced regarding renal infection during pregnancy. Owing to the fact that about 80 per cent of all pregnant women have stasis of the upper urinary tract no matter how normal their course it is not easy to explain why some 99 per cent of them terminate labor without renal complications.

Since Folsom¹ presented his work on the compound racemose glands of the female urethra, there has been a clearer understanding of many postpartum infections traumatized. A resulting lymphangitis, in the presence of pelvic stasis, could readily serve as a nidus for bacterial growth. *Escherichia coli* is the micro organism

His studies point to a possible lymphatic extension from the deep urethra in women to the kidney pelvis. During delivery, infected urethral glands are frequently

most commonly observed in these patients and the staphylococcus group comes next in frequency. Many ascending infections from the bladder, according to Hofbauer,² originate from urinary retention in

¹ Folsom, A. I. The Female Urethra. J. A. M. A. 97: 1345-1350 (Nov. 7) 1931.

² Hofbauer, J. I. Personal communication to the authors.

atomic bladders due to traumatism that viscus sustains during labor. Prather³ observed vesical residual urine in 11 per cent of pregnant cases. He feels that trauma, bladder complications and a flare up of previous infections of the urinary tract mainly explain such complications. Of the postpartum urinary disturbances studied by him, 87.6 per cent occurred in primiparas. This coincides with the figures in our series.

In our opinion, extension from the cervix, as an aftermath of the trauma to which this structure is subjected at delivery, has not been accorded sufficient attention. Aversion on the part of obstetricians to study, microscopically, stained smears of secretion obtained from cervixes immediately after delivery (an attitude eminently sound) makes it most difficult to state with exactness the proportion of cases falling in this category. However, when it is realized that fully 75 per cent of parturient women have endocervicitis, in varying degree, and when studies of Benedict, Von Lackum and Nickel⁴ are recalled, which stress the interrelation between inflammatory diseases of the eye and foci in pelvic organs, it is rational to suppose that the cervix plays a part in the creation of the postpartum kidney.

Hunner⁵ directed attention to the possibility of ureteral stricture as a causative factor in the production of renal infection. We would have been unsuccessful in clearing up at least one of our cases had we ignored his teachings.

Whether the extension is lymphogenous more often than hematogenous is beside the question. Blood stream infections are observed by all urologists, and beyond any doubt some postpartum kidney lesions are to be attributed to this factor. It has become an axiom among cystoscopists that pyelonephritis following delivery and puerperal fever are not infrequently synonymous.

Crabtree and Prather⁶ stress the importance of hospitalization of these cases and prove, by their results, the value of a urologic consultant on the staff of every institution having a lying-in department. They emphasize conservative treatment in kidney ailments during pregnancy, such as forced fluids, rest in bed, urinary antiseptics and sedatives as needed. This plan is to be strongly recommended. When, after a fair trial, it fails to relieve, more energetic means must be employed. The series of cases here reported fall into the latter group.

We reiterate our position relative to internal urinary antiseptics. For the past seven years we have devoted a great deal of attention to this fascinating and controversial problem. Our work has been divided equally between studies in the urologic wards and experimental investigations in the pharmacologic laboratory. All the drugs presently recommended for use in urinary infections have been submitted to extensive and impartial trial. Our conclusions remain in accord with the observations⁷ that of all urinary antiseptics now in use pyridium in doses of from 0.1 to 0.2 Gm., administered orally three times a day, is superior to other drugs. These conclusions are based on having administered the dye in some 3,000 cases over a period of time suffi-

ciently adequate to judge of its merit. Not alone does pyridium retard bacterial growth in the majority of cases but it invariably has a soothing effect on the bladder mucosa not experienced in other drugs.

In the past seven years, 610 cases of pyelonephritis have been treated at the Southern Baptist Hospital, this, from a total of 42,000 admissions, gives an incidence of 1.4 per cent. Of this number of kidney infections, fifty-eight, or 2.4 per cent, occurred among the 2,400 women admitted for delivery. Postpartum kidney infection was observed in thirty-six, or 1.5 per cent. It is with the latter group that we are concerned. It should be remembered that in this postpartum series we were called in consultation because most of the patients were quite ill. Conservative measures had been tried by the attending obstetricians, in nearly every instance without relief of symptoms. Of the thirty-six cases of postpartum renal infection tabulated, twenty-one patients, or 58.3 per cent, had temperatures of 104 or above when first seen. Twenty-four patients, or 66.7 per cent, had pelvic stasis, eleven, or 30.5 per cent, in the right side, five, or 13.8 per cent, in the left, and eight, or 22.2 per cent, in both sides. This stasis varied from 10 to 85 cc. Seven, or 19.4 per cent, left the hospital with from 5 to 20 cc of stasis, twenty-seven, or 75 per cent, were dismissed with no stasis. All but three cases showed marked pyuria and bacteriuria or both. Twenty-eight, or 77.7 per cent, showed *Escherichia coli*, while only three, or 8.3 per cent, showed staphylococci. Seventeen patients, or 47.1 per cent, left the hospital with some evidences of infection still present, these were out-of-town patients and could not be followed to the point of renal sterilization. Seventeen patients, or 47.1 per cent, were discharged with normal urines. One case disappeared early from observation, and in the other cystoscopy was refused.

All these patients were confined to bed in the hospital, as the symptoms were recognized within a few days following delivery. Attempting to keep the lower colon empty with high flushes is routine with us in dealing with infected kidney cases. Seven days on restricted fluids plus pyridium by mouth is alternated with three days of forced fluids plus alkalis. When difficulty is experienced in getting the patient to swallow sufficient water (from six to ten glasses daily), fluids are administered by means of the duodenal tube, by proctoclysis, by hypodermoclysis or by the intravenous Matas drip (physiologic solution of sodium chloride or dextrose being used).

Two types of local treatment were employed to combat the pyrexia and lumbar pain. In thirty-two, or 88.8 per cent, lavage with 0.5 per cent silver nitrate solution through a 7 F ureteral catheter was instilled after the stagnant urine had been aspirated from the pelvis of the kidney. From one to five such treatments at intervals of four days proved most effective. Fourteen, or 41.6 per cent, of the cases were treated with indwelling catheters, usually of sizes from 7 to 9 F, the time allowed for the catheter to remain in place ranging from eighteen hours to two days, the time factor being determined by the amount of stasis and the tolerance of the individual. In thirteen patients, or 36.1 per cent, subjected to indwelling catheter drainage including some of our most refractory cases, this procedure aided materially in shortening the convalescence. By one or the other of these methods, or by combining the two the temperature was reduced to normal in from one to eighteen days. The average time required to relieve patients from fever was five

days. The patient who refused cystoscopic therapy had a continuous high fever for eighteen days, it then dropped to normal but the urine, at the time of discharge from the hospital, still showed pus 4 and *Escherichia coli* 4.

The two fatalities in the series resulted from general sepsis. Whole blood transfusions, by the method of Head, have proved most valuable to us in treating septicemia. However, both of these patients came under observation too late for this procedure to be of assistance.

An analysis of this series reaffirms our previous contention that indwelling ureteral catheters, when used judiciously, cause no ill effects and, in many instances, unquestionably shortened the period of treatment. By adopting catheters coated with gold leaf, introduced by one of us,⁸ the hazards of having urinary salts attack the gum coating on ordinary catheters is obviated thereby doing away with the possibility of traumatizing the ureteral mucosa on withdrawal.

During the past year we have been experimenting with soft rubber ureteral catheters made rigid for introduction by whalebone stylets, and favor them for indwelling purposes when it is found possible to introduce them. Certainly they cause less discomfort than the gum-silk ureteral catheters. Regarding lavage of the renal pelvis with antiseptic solutions, no argument is required to extol further its established place in the treatment of pyelonephritis.

URINARY TRACT INFECTIONS ASSOCIATED WITH PREGNANCY

THEIR FATE IN SUCCEEDING PREGNANCIES

E. GRANVILLE CRABTREE, M.D.

AND

GEORGE C. PRATHER, M.D.

BOSTON

This study is based on a group of more than 400 cases of disease of the urinary tract associated with pregnancy, which have been treated by one or both of us over a period of years, extending from 1919 to the present time. Many of these patients were seen in but a single pregnancy, others have been regular customers at our clinic, and we have been able to compile data covering the complete child-bearing period in a considerable group. Unfortunately, owing to various handicaps that existed in former years, the earlier observations are less complete than those made in later years. Careful selections have been made from these cases, and we have used only proved facts suffering the necessary shrinkage in numbers in the interest of greater accuracy.

A conception of the importance of urinary tract infection in relation to the whole child-bearing period in women is obviously of more importance than observations of one or two isolated pregnancies from the series.

From such an opportunity as had been provided for us between the years 1919 and 1933 to collect material

along these lines we now endeavor to provide answers for the following questions:

1. What types of infection (exclusive of tuberculosis) are associated with pregnancy?
2. Does preexisting infection predispose to pyelitis in pregnancy?
3. What is the probability of cure of preexisting infections during pregnancy?
4. If infections from preceding pregnancies persist uncured into pregnancy, what is the chance of cure in pregnancy?
5. If infection has cleared between pregnancies, is the cure a guaranty of immunity from infection in subsequent pregnancies?
6. What is the relation of infected pregnancies in a series of pregnancies?
7. What influence does the type of infection have on the type of recurrence in a series of pregnancies?
8. What is the relation of gross pathologic changes of the kidney to infections in pregnancy?

TYPES OF INFECTION (EXCLUSIVE OF TUBERCULOSIS)

1. The bacillary infections: pyelitic type, pyelonephritic type.
 - (a) Those cases which either after delivery or cystoscopic treatment show sudden subsidence of symptoms (pyelitic type).
 - (b) Those which under the same conditions subside slowly over a period of days (pyelonephritic type).
2. The coccal infections which behave similarly to the bacillary infections except that there have been noted a few instances of profound sepsis due to various staphylococci and streptococci.
3. Cortical infections due to staphylococci (small abscesses).
4. Carbuncle of the kidney due to staphylococci.

In relation to the stage of the pregnancy, a second classification should be made:

1. Preexisting infection (before marriage).
2. Pyelitis in pregnancy.
3. Postpartum pyelitis.
4. Postpartum cystitis (catheter and constant drainage cases).
5. Intercurrent infection.

Two of the latter classification deserve some comment because they are not usually included in recognized classifications.

The first of these is cystitis. Since the year 1927 it has been our custom to use constant drainage in many of these cases of atonic bladders that follow delivery. These cases and certain of the intermittent catheterization cases show a pure cystitis.

There have also been recorded instances of infections that have occurred between pregnancies, often remote from the preceding pregnancies (in one instance eleven years before the pregnancy with which an infection occurred), which are clearly not to be looked on as persistent infections from preceding pregnancies.

The cases so recorded are:

Intercurrent infection between the second and third pregnancies. The third pregnancy was uninfected but there was a pyelitis with the fourth.

Diagnosis of a strictured ureter with infected urine was made between pregnancies which were widely separated. The stricture was treated but the infection was not cured. Pyelitis occurred with the succeeding pregnancy.

After a normal third pregnancy with no urinary complications a pyelitis developed seven months after delivery. Pyelitis occurred with the succeeding pregnancy (fourth).

Intercurrent infection after the fourth pregnancy, no infection with fifth, sixth, seventh and eighth, but pyelitis with the ninth.

⁸ Walther, H. W. E. Gold Leaf Coated Ureteral Catheters. J. Urol. 23: 287-288 (Feb.) 1930.
From the Urological Clinic of the Boston Lying In Hospital.
Read before the Section on Urology at the Eighty-Fourth Annual Session of the American Medical Association, Milwaukee, June 16, 1933.

Intercurrent infection between the sixth and seventh pregnancies which was not cured. A mild pyelitis occurred with the seventh.

These cases seem to be on a par with other preexisting infections. They tend to recur when not cured before the beginning of the next pregnancy. If cured, the succeeding pregnancy may remain free from infection.

PREEXISTING INFECTIONS

These data are limited to patients in their first pregnancy in order to eliminate the possible effects of pregnancy on the urinary tract. Thirty-three cases were found in which the patients appeared in the clinic well advanced in pregnancy, giving a history of urinary tract infection dated at any period from early childhood on to the beginning of pregnancy.

Histories of past infections are given in the order of frequency, exclusive of tuberculosis.

Pyelonephritis and cystitis, adult
Pyelitis in childhood
Postmarital cystitis, often with pyelitis
Cystitis symptoms alone
Stone associated with infection

Twenty-seven cases presenting such histories were negative throughout the pregnancy. Six patients were infected when first seen but may not have been free from infection at the beginning of pregnancy.

TABLE 1—Type of Infection

Partly	Infection	Cured in
1	Postmarital infection	3d month
2	Mild postpartum in primipara	2d month
1	Cystitis and right pyelitis of 9 years standing, thought to be cured but appeared in third month of pregnancy	4th month
1	Pyelitis of pregnancy in second month	8th month
1	Cystitis only early in pregnancy	2d month
5	Cystitis only with cystocele	9th month

In addition to the thirty-three cases, seven patients were seen who were known to have had a preexisting infection present at the beginning of the pregnancy. The type of disease was as follows: pyelonephritis (adult), four cases; postmarital infection, two cases; cystitis symptoms with pyuria, one case.

Of these seven cases one postmarital infection was cured in pregnancy. The other six patients all developed fever and had symptoms of pyelitis.

From these data it seems probable that the history of cured preexisting infection is not important in prognosis. The majority of infected patients entering on their first pregnancy will have febrile symptoms. From other data, cure in the course of pregnancy is probably not to be expected to occur as frequently as once in seven cases.

CURE IN PREGNANCY

Most observers have agreed that, when infection is present in the urinary tract at the beginning of pregnancy, cure in pregnancy is an extremely rare occurrence. In our clinic we have considered cured patients whose urines are negative for pus cells and bacteria when examined by wet preparation and stained sediment made from centrifuged concentrated urine specimens on at least three successive occasions at intervals of two weeks.

In all types of cases encountered cure of infection has been proved in only six cases. These are classed in regard to type of infection in table 1.

It is to be noted that cure in pregnancy is most apt to occur in the early months of pregnancy before pelvic

and ureteral dilatation take place. One cystitis in a multipara was cured late in pregnancy. One severe pyelitis of pregnancy was cured late in pregnancy.

PERSISTENT INFECTIONS FROM PREVIOUS PREGNANCIES

Fifty-three patients carried infection over between pregnancies into eighty-six pregnancies. Other pathologic conditions in addition to infection were present five times. Two were cortical abscesses in which operation was eventually done during pregnancy. Two cases showed stone, in both of which operation was eventually done between pregnancies; these patients were cured of infection and have had uninfected pregnancies since. One was a cystocele with residual bladder urine. One patient was thought at one stage to be cured in pregnancy but did not prove to be so. All eighty-six pregnancies were infected and renal infection was confirmed by typical symptoms, cystoscopy or both. The majority had intravenous or retrograde pyelography in one or all of the pregnancies.

From these data it seems almost certain that a patient who carries over an infection from a previous pregnancy into the next gestation will have an infected pregnancy.

RELATION OF CURE AND ABSENCE OF INFECTION IN SUBSEQUENT PREGNANCIES

For this study there are twenty-six cases available in which there has been infection of the urinary tract associated with pregnancy, which has been followed immediately by other pregnancies that have been free from infection. Sixteen cases were pyelitis of pregnancy, two of which recurred in the succeeding pregnancy before cure was effected, five were postpartum infections, three were only cystitis, due to constant drainage placed for atonic bladder conditions, and two were associated with other pathologic conditions (stricture) which was treated, and the infection cleared between pregnancies. In one of these the infection was afebrile, in the other severe.

Two of these cases belong to the group in which cure of the infection took place in the course of the first pregnancy. One was a preexisting infection, which disappeared during the first two months of the first pregnancy and remained absent through the second pregnancy; the other was an infection that had been present for two and a half years preceding the first pregnancy, gave rise to a pyelitis in pregnancy which was quite severe, yet disappeared in the eighth month and was followed by one uninfected pregnancy. In one case a cure in pregnancy was questionable but since a postpartum infection appeared on slight provocation the cure is not established.

Of the pyelitis cases, one was severe and was cured during pregnancy; another, associated with stricture, was severe in its onset but subsided, and the patient finished the pregnancy comfortably. The remainder were average cases of the disease.

Two of the postpartum cases were severe, one occurred seven weeks after delivery but was probably not an intercurrent infection. Three cases were mild.

In the three cystitis cases there was no fever.

One of the patients who had two infections in succeeding pregnancies had a severe condition with the first infected (seventh) pregnancy and an afebrile infection with the eighth, but remained uninfected with the ninth.

Seven cases occurred in a group of sixty-three patients in which there was cure of infection between

pregnancies but in which a pyelitis in pregnancy followed. This rate of recurrence is far above the normal incidence of infection in pregnancy, which is now accepted as somewhere about 1 per cent. Either the

cure was only apparent or there are other factors that should enter into the picture to explain recurrence of infection. We believe that the latter point of view represents the facts. Economic factors affecting both diet and work in care of the family, water drinking and general hygiene, and the anemias of pregnancy are suggested causal factors.

One patient with very serious pyelitis, with extreme dilatation of the right kidney, became pregnant within three months of the end of the preceding pregnancy.

but after cure had been effected. There was no infection in the pregnancy.

From these data it appears that cure during the course of pregnancy may occur after a severe infection with pelvic dilatation of considerable degree. Afebrile pyelitis may occur in association with stricture. A severe pyelitis in pregnancy may be followed by an afebrile infection in succeeding pregnancies. Close approximation in pregnancies may occur without infection in the succeeding pregnancies, if cure has been accomplished.

The important deduction to be drawn from such conflicting data is that the cure of the infection before the beginning of the succeeding pregnancies, even though special treatments or surgery are indicated to produce that result, is the essential consideration.

However, there are scattered cases encountered either when uninfected pregnancies intervene between infected pregnancies or when an infected pregnancy occurs in a series after cure between pregnancies has taken place.

* An intercurrent pyelitis.

Yet such far greater numbers of cured patients have uninfected pregnancies follow, and infected pregnancies follow when uncured, that this relation is to be considered the logical sequence and the sporadic cases exceptions to the rule.

RELATION OF INFECTED PREGNANCIES IN A
SERIES OF PREGNANCIES

There are available sixty-three cases in which there have occurred 299 pregnancies, an average of 4.7 pregnancies per patient. The smallest number of pregnancies is two each, both infected, which occurred in seventeen cases. The largest number of pregnancies was twelve. Of these, 133 pregnancies were infected. Two of the patients had stone and one had cortical abscess. Stone appeared with the fifth pregnancy in one case and with the tenth in another. The cortical abscess appeared in the second pregnancy in a previously uninfected patient. In all cases the following pregnancy was infected also. One case was an intercurrent pyelitis between the second and third pregnancies which was probably not cured, because symptoms persisted although the third pregnancy was afebrile but the fourth was febrile.

Table 3 shows the time in the series at which the first infection appeared. No attempt is made here to indicate either the type of infection, its severity or whether cured between pregnancies, since only the relation of infected pregnancies to other pregnancies is the information desired. In four cases only one infection occurred in a series of ten or more pregnancies.

Of these multiple infections, primiparity marked the onset of the highest number of cases of any gestation. The complete list is given in table 3.

Table 4 shows graphically the location of the infected pregnancies in the series.

From table 4 it is apparent that there is a serial relation between infected pregnancies. There are only three assured cases in which intervening pregnancies were infected. In five cases there were other pregnancies that were uninfected following a series of infected pregnancies. In one of these there were four such pregnancies.

Whatever the factors concerned in producing infection, they appear to persist beyond the single pregnancy, since infected pregnancies appear to occur in series, even though the urine is clear of infection in the interval between pregnancies in some instances.

AFEBRILE INFECTIONS

In a series of multiple infections, some remain febrile while others produce pronounced symptoms. It is generally recognized that severe pyelitis symptoms may and usually do usher in initial infections, yet such symptoms usually subside, the urine remains purulent throughout the pregnancy, and dilatation of the ureters and pelvis persists. Tolerance for infection seems to have been required. It is logical to assume that such tolerance for infection extends beyond a single pregnancy for the following reasons. Of 109 infected pregnancies occurring in fifty-two patients, the initial infection was a severe febrile reaction either as a pyelitis in pregnancy or a postpartum infection in forty-eight cases. In three the first infection was afebrile and in one, mild in character. In the four mild and afebrile cases infection was present for some time before the onset of pregnancy—nine years in the longest standing case and six months in the shortest.

Second infected pregnancies occurred forty-nine times, febrile fifteen times, afebrile twenty-six times and mild eight times.

Third infected pregnancies occurred nine times, two were febrile and seven afebrile.

There seems to be abundant evidence here to support the view that acquired tolerance for infection persists into subsequent pregnancies.

ASSOCIATION OF GROSS RENAL PATHOLOGIC
CHANGES WITH INFECTIONS OF THE
URINARY TRACT IN
PREGNANCY

Gross pathologic changes of the urinary tract is not common in the child-bearing period. Since universal pyelography was not done, no doubt many uninfected lesions were missed. Fifty-five cases of urologic conditions are recorded. The incomplete list in table 5 may serve at least to indicate the variety of lesions encountered.

Cystocele was a very uncertain quantity to estimate but was frequently encountered.

Of this group of "other lesions," all the stone cases except one, all the hydronephroses, strictures and the polycystic kidney were infected during pregnancy.

The malformed ureters and unrotated kidneys were uninfected.

TABLE 5—Variety of Lesions Encountered in Series

Condition	No of Cases
Calculus (renal 7 ureteral 5)	12
Tuberculosis (chronic 5, acute in pregnancy 1)	1
Hydronephrosis (unilateral 1 bilateral 2)	3
Congenital malformation* (unrotated kidney 2 congenital ureter 1 double ureter 1)	4
Strictured ureter	3
Hematuria (unexplained)	3
Endocervicitis (gonorrheal)	4
Cortical abscess	2
Cirrhosis of kidney	1
Incontinence	3
Papilloma	1
Polycystic kidney	1
Retroversion of pregnant uterus with acute retention	1
Uolds standing (retroversion)	1
Frequency (trigonitis)	4
Ovarian cyst with bladder symptoms	1
Back strain with bladder symptoms	1
Renal pain before during and after pregnancy probably explained by ptosis	6

While hematuria has been the initial symptom of pyelitis of pregnancy, on nine occasions hemorrhage from the kidney occurred three times in cases in which there was no other cause assignable except pelvic and ureteral dilatation of the normal type found in pregnancy.

When infection occurred in association with gross pathologic changes it persisted through succeeding pregnancies (with one exception, cystocele) until the underlying condition was remedied and was not always cured then, as in some stone cases. The polycystic kidney remained infected over a period of five years but eventually cleared. The patient had been sterilized soon after the condition was discovered.

It is our practice to correct underlying gross pathologic changes immediately in the course of the pregnancy when conditions demand, but preferably in the intervals between pregnancies. In patients in poor condition it seems wiser to interrupt the pregnancy and make the surgical correction between pregnancies.

It is to be noted that not all gross pathologic conditions become infected during pregnancy.

ABSTRACT OF DISCUSSION

ON PAPERS OF DRs WALTHER AND WILLOUGHBY AND
DRs CRABTREE AND PRATHER

DR A I FOLSOM, Dallas, Texas. These two interesting papers give accurate analyses of the sources of urinary infections in pregnant women. Less is known about urinary infections in pregnancy than about anything else in urology. Certain factors seem to indicate that the question of pressure, so far as obstruction is concerned, does not play as great a part as has been thought. I am particularly interested in the part played in these conditions by the posterior portion of the urethra. Drs Crabtree and Prather recite a number of cases of cystitis. As a rule they are instances of a long-standing urethritis and not pyelitis. The extension into the bladder is a secondary process. Professor Lichtenstein called attention to the close association between lower urinary tract infection and upper urinary tract infection in men. This is well recognized, but little attention has been paid to the same condition in women. In autopsy specimens in the female bladder I found a large number of papillary masses. This is not a passive thing but a real papillary obstruction, an active inflammatory condition. In the base of the mass there is an active inflammatory area. In some cases the picture is almost identical with a collaret prostate. In some there is a compound structure with many branches, but the long-standing infection produces the collaret appearance just as it is found in the prostate. The long-standing latent infection in these cases is understandable. These infections in the female urethra are aggravated during pregnancy. It does not take much imagination to see that the passage of the head through the birth canal will traumatize tissues and produce trouble. These tissues are composed not of cysts but of definite gland structures, and this focus of inflammatory tissue at the neck of the bladder in pregnant women becomes activated, produces a large amount of irritation and in many instances leads to an infection which ascends through the lymphatics to the kidney.

DR G C PRATHER, Boston. This idea of secondary infection being due to traumatism of an infected cervix or of a urethral obstruction, according to Dr Folsom, offers a possible explanation concerning etiology. Many women have an elevation of temperature post partum. The obstetrician reports that there is some infection with pus cells present in the urine, and he wishes to know whether this comes from urinary tract infection or not. These cases offer an interesting problem and, when the fever continues, cystoscopic examination gives extremely valuable information. I do not hesitate to obtain a pyelographic diagnosis in these patients, believing that a continued elevation of temperature from the upper urinary tract, in the absence of an enlarged uterus, indicates a condition that can be improved by cystoscopic or surgical procedures. While our limited experience with pyridium in ambulatory cases was not encouraging, I feel inclined to regard the favorable report of Dr Walther seriously, for it seems to me that 3,000 cases observed for a sufficient period of time offer adequate data for conclusions. An incidence of postpartum kidney infection of 14 per cent during the period 1925-1929 was mentioned. In our first series the incidence of that condition at the Boston Lying-In Hospital was 0.4 per cent of pyelitis in the entire hospital. During the last four years, with more vigorous care, the proportion of postpartum pyelitis has been reduced to 0.25 per cent. The average of only five days of fever after the beginning of cystoscopic treatment in these patients, either by kidney lavage or by constant ureteral drainage, I believe is very creditable as well as having nearly 50 per cent of the patients with urine normal before leaving the hospital. We do not repeat the cystoscopic procedure in our postpartum series, after the temperature has become normal, until from three to four months has passed, believing that a definite number will clear the urine of bacteria and leukocytes in that time on a forced fluid regimen. If they are not normal by the end of that time they are investigated urologically and treated more actively. In regard to the fact that these ureters and kidneys shrink down quickly after delivery, one observation is interesting, and that is that they do not regain their sensory qualities very quickly as can be shown by injecting

from 15 to 25 cc through a No 9 catheter without pain into the postpartum kidney pelvis, which has a normal pyelographic appearance. In other words, these kidneys have shrunk down but have not regained full sensation.

DR ANSON L CLARK, Rochester, Minn. The authors of these papers have focused attention on a condition that should be treated with much closer cooperation between obstetrician and urologist than it has been in the past. Drs Crabtree and Prather have brought out clearly that cases of infection of the urinary tract which do not recur in subsequent pregnancies are those which have been entirely cleared up following termination of the previous pregnancy. From a urologic standpoint it would seem that, when a patient has had a history of pyelitis in pregnancy, careful bacteriologic study of the condition during the postpartum period should be made. Frequently, considerable attention is paid to the condition and position of the uterus during this time, but often careful bacteriologic examination of the urine is neglected. Six or eight weeks following delivery, sufficient general physiologic recovery of the urinary tract would have taken place to warrant microscopic examination of a stained smear of the catheterized urine and a culture of urine. At this time, should the infection still be present it would seem to indicate a more concentrated attack entirely to dislodge the infection, which in many cases is practically asymptomatic after such an interval has elapsed. In confirming the belief of Drs Walther and Willoughby that the possibility of extension from the cervix has been neglected, the work of Richards, reported in THE JOURNAL Oct 29, 1932, is of interest. He has proved that transient bacteremia is much more common than it usually is considered to be. Immediately following trauma to possible foci of infection the organism was yielded by cultures of the blood in from 10 to 20 per cent of the cases. One hour later blood cultures in practically all the cases, excepting those involving the tonsil as a focus, were negative. If one is to believe that the hematogenous route of infection is to be considered in infections of the urinary tract, this work is extremely interesting. I cannot agree with Walther and Willoughby in their recommendations as to the use of pyridium. Gillespie, in his work with Helmholtz, has conclusively proved that pyridium in aqueous solution is bactericidal but that pyridium in a solution of urine at stronger concentration than it is possible to pass through the urinary tract is not bactericidal. This was confirmed by Edwin Davis one year ago. I would urge that, in the majority of cases of postpartum infection, inhibition of the growth of the offending organism be effected before investigation by ureteral catheterization, which might cause trauma, is instituted. Marked acidification of the urine by either ammonium nitrate or ammonium chloride given orally would seem advisable before deciding that drainage by catheter of the upper part of the urinary tract is necessary. My experience has shown numerous cases in which too early catheterization of the upper part of the urinary tract, in the presence of a virulent infection, has led to complications rather than to amelioration of the condition.

DR J I HOFBAUER, Baltimore. More emphasis should be placed on atony of the ureter during pregnancy, rather than dilatation. I cannot understand how the ureter may be supposed to dilate during early pregnancy by reason of uterine pressure, as the ureter does not come in contact with the uterine wall to any extent in the early months of pregnancy. Lowering of the surface tension of the blood primarily accounts for ureteral atony in pregnant women. An excellent piece of work, recently published by the Mayo Clinic, in corroboration demonstrates decrease of tone of the biliary ducts during pregnancy. During the sixth and seventh months of pregnancy, when the ureter comes in close contact with the uterus, the atonic ureter is displaced outward. The juxtavesical portion of the ureter does not dilate in normal pregnancy but it may dilate in cases of pyelitis of pregnancy. Infection adds another element for the occurrence of atony, and this is demonstrable on the screen. Why does the right ureter more often show dilatation during pregnancy than the left? In my opinion this is due to the fact that the uterus, as a rule, lies in definite torsion to the right. Realizing that in the later months of pregnancy, owing to the formation of the lower uterine seg-

ment, the bladder is pushed forward and to the right, I feel that the left ureter is put on a stretch while the right ureter angulates at the point where it traverses the parametrium. Why is it that pyelitis does not occur in every case of ureteral dilatation, in the presence of bacteria? The third determining factor is the lowering of the resistance of the organism. My studies have shown that in pregnant women there occurs a lowering of resistance to *B. coli* in about nine out of a hundred cases. The same phenomenon occurs in women following labor when there is excessive loss of blood. With the idea of possibly preventing the occurrence of pyelitis by stimulating the peristaltic activity of the ureter, I now give pregnant women from the fifth month of pregnancy on calcium and potassium citrate in large doses and twice a week ephedrine orally and have reduced the occurrence of pyelitis to about $\frac{1}{3}$ per cent.

DR E. G. CRABTREE, Boston. There was no doubt that the cases to which Dr. Folsom referred were cases of cystitis without involvement of the upper urinary tract. Absence of upper urinary tract infection while not proved in every case, was demonstrated in some. Residual urine during the course of pregnancy has been mentioned. After several years of following our cases in this regard we do not find residual urine except in rather unusual conditions and when there is a cystocele. Dr. Hofbauer has brought up many interesting questions. I assign a double cause for the dilatation of the ureter and pelvis in pregnancy. This is atony of the ureter and pelvis as a result of endocrine changes due to pregnancy and pressure applied by the uterus at the brim of the pelvis. It may be recalled that Jacoby a number of years ago contended that the whole body of the pregnant woman undergoes loss of tone. This loss of tone in the ureter and pelvis undoubtedly takes place throughout its course, yet only that portion of the ureter dilates which is situated above the point of pressure at the brim of the pelvis. Hypertrophic conditions which Dr. Hofbauer has accurately reported, at the ureterovesical junction and lower part of the ureter do occur but I do not believe that they play much part in the production of the dilatation because as indicated by Kretschmer, the lower portion of the ureter does not as a rule, take part in the ureteral dilatation. I explain lateral displacement of the ureter by recalling that the ureter is more adherent to the peritoneum than to the postretroperitoneal tissue, therefore peritoneal stretching will carry the ureter beyond its normal position.

DR H. W. E. WALTHER, New Orleans. The trail blazers in the field of postpartum urinary sepsis have been Hofbauer, Crabtree and Prather, and I wish to pay them respectful tribute. It has been the stimulating tenor of their work that has encouraged us to carry on with our study. We shall continue our work with pyridium in order to report later whether we feel the same as some do or whether we shall retain our present high regard for this dye antiseptic. Certainly no convincing evidence has yet been advanced to show that pyridium, when administered in proper dosage and over a sufficient period of time, is not therapeutically effective. Davis attempted to solve this problem by showing that bacteria would grow in the voided urine of normal medical students who had taken various dyes by mouth. Helmholtz substitutes rabbits for test tubes. Neither of these studies proves anything of clinical value. Physicians are not called on to treat test tubes or rabbits. Admitting the intricacy of investigations in dye therapy we do not feel that the final evaluation of pyridium will be settled in the laboratory.

Observational Ability.—Diagnostic success at the bedside may be held to depend first upon the historical analysis and secondly upon our personal powers of observation both of which are subject to the continual leaven of experience. Nothing is so variable as observational ability. Some have it well developed from childhood, men of the naturalist type. Some never acquire any facility for it and repeatedly miss the clue. The majority cultivate their aptitudes by degrees and attain a middle level. Most of us improve with time and practice but many take but little pains to refine and to register experience and for this reason retard their progress in the clinical arts.—*Rule 1 A. The Training and Use of the Senses in Clinical Work. Guy's Hosp. Gaz.* 47:421 (Oct. 23) 1933.

PATHOLOGIC PHYSIOLOGY OF TERATOMA TESTIS

RUSSELL S. FERGUSON, M.D.

NEW YORK

Observations pointing to the direct relation of specific tumors to certain ductless glands are increasing. To this number the relation of teratoma testis to the anterior lobe of the pituitary may now be added.

Since December, 1930, there have been observed at the Memorial Hospital 117 consecutive cases of tera-

Fig. 1—Teratoma of the testis. Embryonal adenocarcinoma.

toma testis in which the quantitative excretion of prolan A (the follicle-ripening hormone of the anterior pituitary body) has been determined by multiple observations. The technic of the quantitative modification

Fig. 2—Teratoma of the testis. Embryonal carcinoma with lymphoid stroma.

of the Aschheim-Zondek test¹ has been published elsewhere and need not be repeated at this time.

From the Memorial Hospital.
Read before the Section on Pathology and Physiology at the Eighty-fourth Annual Session of the American Medical Association, Milwaukee, June 14, 1933.
¹ Aschheim, S. and Zondek, B. *Klin. Wchnschr.* 1:94, 1928.

Am. J. Cancer 15:55 (April) 1931. Ferguson, R. S. *ibid.* 18:269-9, 1933.

In all the cases in this series in which the tumor had been unaffected by treatment, prolan A was found in the urine in varying amounts. The factors which determine the urinary excretion of prolan A are as follows: (1) the embryonal character of the tumor, (2) the extent of the disease and (3) the effect of treatment.

OBSERVATIONS

No cases of chorionepithelioma of the testis appear in this series. On the basis of the published observations of Heidrich, Fels and Mathias - and comparable observations in cases of chorionepithelioma of the

uterus (fig 2). Ten cases of seminoma were observed. The excretion of prolan A varied from 400 to 2,000 units per liter (fig 3). In five cases with adult types of teratoma the output of prolan A varied from 50 to 500 mouse units per liter (fig 4).

Fig 3—Teratoma of the testis seminoma type

Fig 4—Teratoma of the testis, adult type.

uterus, it is safe to assume that this tumor will cause the excretion of prolan A in the urine in excess of 50,000 mouse units per liter. In this series there were seven cases of embryonal adenocarcinoma of the testis which were uninfluenced

by treatment. It will be seen therefore, that the quantitative excretion of prolan A is a definite indication of the structural type of the tumor. In fact, the limits reached by each type overlap so little that it is possible to make the diagnosis on the basis of this determination alone. It has been observed repeatedly in this series that tumors of like structure vary with the extent or mass of the disease. For example, in a case of embryonal carcinoma with lymphoid stroma, without metastases, the excretion of prolan A may be only 2,000 units per liter. In a second case with widespread metastases the

Fig 5—Patient F S. Embryonal carcinoma with lymphoid stroma. The solid line indicates excretion of prolane A in mouse units per liter. The dotted line indicates irradiation in roentgens. The Roman numerals indicate treatment directed to recurrence of the same number as in the diagram.

by treatment at the time of the first assay of the urine. The excretion of prolane A ranged from 10,000 to 40,000 mouse units per liter in each case (fig 1). In fifteen cases of embryonal carcinoma with lymphoid stroma, uninfluenced by treatment, the output of hormone varied from 2,000 to 10,000 mouse units per

liter (fig 2). Likewise, wide fluctuations have been observed in the same case. With a small mass of tumor the output in case 49 was only 2,000 units per liter, later, when widespread metastases were present, the output reached 10,000 units of prolane A per liter of urine (fig 5).

THE EFFECT OF TREATMENT

Observations on the effect of treatment on the excretion of prolan A in teratoma testis are practically confined to the effect of irradiation. The 117 patients in this series were treated by means of high voltage roentgen therapy or radium element pack. In 5 cases the excretion of prolan A was unaffected by maximum doses of radiation. In such instances the prognosis is bad and these patients are either dead or dying (fig 6)

Fig 6—Patient I A Excretion of prolan A unaffected by high voltage x rays Prognosis bad

In the majority, however, irradiation of the primary tumor or its metastases caused a drop in the excretion of prolan A in the urine, the rapidity and extent of which are good indexes of the radiosensitivity of the tumor, and reliable factors on which to base the prognosis. In case 71 the rapidity of the drop in excretion of hormone and the effect of the irradiation on the tumor are shown in figures 7 and 8

With respect to the surgical removal of the primary tumor in cases without metastasis, if the presence of a measurable output of prolan A before operation may be assumed, the prolan is known to be absent as soon as seven days after operation

As already observed, irradiation of the primary tumor and its metastases causes a decrease in the excretion of prolan A in most instances. In these cases there is a coincident decrease in the size of the tumor and its metastases and in favorable cases a total disappearance of the same. In three instances the pituitary gland has been irradiated, and while there was an easily demonstrable reduction in the excretion of prolan A in the urine there was no measurable reduction in the size of the tumor or its metastases. At the same time it could not be said that the tumors increased in size

RECURRENCE AND METASTASIS

The effect of recurrence and metastases on the excretion of prolan A has been observed repeatedly. The metastatic lesions of teratoma distribute themselves in the abdominal and mediastinal lymph nodes and through the venous circulation into the lungs. In these locations it is difficult to detect their presence early by clinical methods. In all of the recurrent cases in this series an increase in the excretion of prolan A in the urine was observed anywhere from two weeks to three months before the metastatic lesions became clinically demonstrable (fig 5)

PHYSIOLOGIC EFFECT OF PROLAN A ON GENITAL EPITHELIUM

The increased secretion of prolan A occasioned by the presence of a teratoid tumor in the host produces profound changes in the genital epithelium of young subjects. Ten cases in this series came to autopsy. In each there was an easily demonstrable hyperplasia of the epithelium in the prostate and seminal vesicles. This reached such proportions, in cases succumbing with a high output of prolan A, that the prostate was indistinguishable from that of the benign hypertrophy of old age, except for the fact that the muscle and stroma took little part in the hyperplasia (figs 9 and 10). In the opposite testis of such cases there is a constant hyperplasia of the interstitial cells with atrophy of the seminal epithelium (fig 11). The pituitary body constantly shows the basophilic hyperplasia typical of pregnancy (fig 12)

Prolan A has been demonstrated in the tumor tissue in all the cases in which autopsies have been made. The amount is usually comparable with that found in the urine just before death

Fig 7—Patient H S Prompt appearance of prolan A from the urine in a radiosensitive teratoma of the testis Prognosis good

COMMENT

The cause of the appearance of prolan A in the urine of patients with teratoma testis is a subject for speculation. The most likely possibility presumes that the origin and growth of the embryonal tumor produce a hormone, not yet identified, that stimulates the anterior lobe of the pituitary body to secrete an increased amount of prolan A. In support of this contention, the identical structural changes observed in the anterior

4 Ferguson R S Am J Roentgenol 29 444 (1935)

lobe of the pituitary body in cases of normal pregnancy, chorionepithelioma in the female, teratoid tumors in the male and certain other neoplastic diseases accompanied by high outputs of prolan A in the urine may be cited. The hyperplasia of the basophilic cells of the anterior lobe is a characteristic feature in all of these cases. Zondek,⁵ in a recent paper, has produced exact evidence tending to prove that the basophilic cell of the anterior lobe is responsible for the secretion of prolan A. Further, roentgen irradiation of the pituitary body in

Fig 8—The tumor from case 71 (fig 7) removed six weeks after completion of irradiation. Note entire destruction of this radiosensitive teratoma.

cases of teratoid tumor of the testis causes a temporary decrease in the excretion of prolan A in the urine. The beneficial results of preliminary irradiation of the pituitary body in cases of corpus carcinoma, as reported

Fig 9—Hypertrophy of the seminal vesicles with the true epithelial hyperplasia due to the sex hormone of the anterior hypophysis (Autopsy Patient N. D.).

by Voltz to the League of Nations Committee would appear to be predicated on the fact that, in many of these cases excessive amounts of prolan A are secreted in the urine (Zondek⁶).

This theory also agrees with a corollary which has many ramifications, namely that prolan A is essential to the growth of embryonal tumors of the testis. It

has been shown by Zondek with direct tumor transplants, and by me with tumor extracts, that these tissues contain more prolan A than can be found in an equal volume of blood. It is here shown that irradiation of the primary tumor or its metastases causes a decrease in the excretion of prolan A in the urine. Irradiation of the hormone *ex vivo* is without effect. The total disappearance of the hormone from the urine coincides with the clinical disappearance of the tumor and its metastases, without any treatment having been directed at the pituitary body. The hormone reappears in the urine whenever the tumor recurs. This would seem to prove that the tumor requires prolan A as an essential to growth, and that the tumor actually produces a precursor which stimulates the anterior lobe of the pituitary body to secrete prolan A. In further support of the main theory and its corollary is the evidence herein deduced that the quantitative production and excretion of prolan A are in direct proportion to the growth rate of the tumor, since the more rapidly growing embryonal tumors cause the production of larger amounts than the more adult types.

Fig 10—Hypertrophy and epithelial hyperplasia of the prostate (Autopsy patient N. D.).

To one directly engaged in such studies the conclusion is inescapable that the biologic approach to the study of the disturbed endocrine physiology of the tumor host is a fertile and until recently untilled field of cancer research. That this conclusion is not unwarranted in fact is shown by the present study and by the work of Jaffe and others on the relation of the parathyroid to osteitis fibrosa and by unpublished studies from this laboratory which show a direct relation between the middle lobe of the pituitary body and melanoma. The practical applications of such studies to diagnostic methods and the control of therapy are suggested in the results herein reported.

SUMMARY

1 The factors determining the quantitative excretion of prolan A in the urine in 117 cases of teratoma testis are briefly enumerated.

2 It is shown that the excretion of prolan A is determined by the embryonal character of the tumor, the extent of the disease and the effect of treatment.

3 The effect of recurrence and metastasis on the excretion of prolan A in cases of teratoma testis is described.

4 The structural and physiologic changes in the prostate, vesicles, testes and pituitary body of the tumor host are enumerated

5 The significance of the foregoing findings is discussed

ABSTRACT OF DISCUSSION

DR FRANK W. HARTMAN, Detroit The constant application and refinement of these tests are more important than the original application and discovery I should like to ask

Fig. 11—Hyperplasia of Leydig's cells in the remaining testis (Autopsy patient N. D.)

Dr. Ferguson the details of his test what animals he uses whether he has to concentrate the urine and a few practical points that would be of great interest to all

DR R. S. FERGUSON, New York The details of the quantitative technique are rather lengthy They appear in the

Fig. 12—Anterior lobe of the pituitary showing basophilic hyperplasia (Autopsy patient N. D.)

June issue of the American Journal of Cancer The whole procedure is totally useless and will come into immediate disrepute if observers insist on doing qualitative tests for prolan A and on finding nothing state that the whole procedure is useless No qualitative Aschheim Zondek test on rabbits rats mice or any other animal is sufficient to demonstrate less than 2,000 units per liter as a gross reaction Therefore more than 99 per cent of the value of the work will be immediately lost because one third of the tumors do not secrete 2,000 units per liter yet that is not to say that they do not secrete prolan A

it is to say that it has not been found I would emphasize that the quantitative method, making an extract of the urine and assaying the extract down to quantities as low as 100 units per liter is essential to results Likewise, in studying teratoma, it is essential to make repeated examinations, week after week as the cases are under treatment

CUTANEOUS ULCERS TREATED BY THE SULPHYDRYL CONTAINING AMINO-ACID CYSTEINE

LOUIS A. BRUNSTING, M.D.
AND
DAISY G. SIMONSEN, Ph.D.
ROCHESTER, MINN.

The treatment of cutaneous ulcers by sulphhydryl compounds is a clinical application of the investigations of Hammett¹ and of Hammett and Reimann² who found, in a long series of experiments on plants, lower animals and man, that there is a positive correlation between the sulphhydryl (SH-) group and cellular activity. Reimann³ reported favorably on the treatment of obstinate cutaneous ulcers by means of thiocresol, which contains sulphhydryl attached to the benzene nucleus. Dressings were saturated with a solution of thiocresol, diluted 1:10,000, and applied to the wounds for periods of a few days, alternating with bland treatment for a similar period. There were distinct spurts of healing during the time the thiocresol was applied, as shown by epithelial growth and a change in the character and amount of granulation tissue.

Following the separation of glutathione in crystalline form, Kendall⁴ suggested to us the use, in a similar practical fashion, of this naturally occurring substance which contains sulphhydryl. Reduced glutathione contains the sulphhydryl group in the form of the amino-acid cysteine, together with glutamic acid and glycine. Glutathione is found in all living tissues and probably plays an important part in cellular metabolism in regard to the activation of enzymes.⁵

We applied reduced glutathione to certain types of cutaneous ulcers and noted a definite stimulation of growth in the treated portions. On account of the expense involved, it was considered impracticable to carry on the extensive use of glutathione, once the academic question of its usefulness had been settled, and for that reason the amino-acid cysteine was substituted. This report deals with the experience gained in a period of three years of the practical use of cysteine in the treatment of selected cases of cutaneous ulcer in the Mayo Clinic, both in ambulatory and in hospital practice.

Read before the Section on Dermatology and Syphilology at the Eighty-Fourth Annual Session of the American Medical Association, Milwaukee, June 14, 1933.

PREPARATION OF CYSTEINE AND METHOD
OF APPLICATION

Cysteine was prepared by the method of Gortner and Hoffman⁶ from the hair of man. Such keratin-containing structures as hair, nails, hoofs, horns and sheep wool are particularly rich in sulphur, most of which is present in the form of the disulphide cystine.⁷ By hydrolysis, hair is converted to cystine, when it is reduced by tin and hydrochloric acid to cysteine hydrochloride. Cysteine (SH⁻) is readily oxidized to cystine (S-S) by exposure to air but can be kept indefinitely in the form of the hydrochloride.⁸

Cysteine was made up in a concentration of 0.5 per cent, the solution containing equal parts of physiologic solution of sodium chloride and distilled water. The hydrochloric acid of the cysteine hydrochloride was neutralized with sodium hydroxide to a pH of 7.0. One gram of cysteine hydrochloride requires 6.35 cc of normal sodium hydroxide or its equivalent. The neutralized solution should be used within twenty-four hours, however, in well filled bottles we were able to keep it in refrigeration for several days without much loss. Dressings were changed twice daily, or more often if there was much drainage.

In our experience, cysteine is not only fully as efficient as thiocresol in stimulating qualities, but it possesses two decided advantages from a practical standpoint. It is without the unpleasant, penetrating odor resembling burnt rubber, common to all volatile sulphhydryl compounds. Furthermore cysteine is less irritating than thiocresol to the surface of skin adjoining the ulcers. The wet dressings, of course contribute to a certain degree of soggy in either case unless care is taken to alternate the treatment with periods of drying.

OBSERVATIONS

More than 200 patients were subjected to treatment by cysteine, a varied assortment of ulcerative lesions were represented. The most common were varicose ulcers usually associated with varicose veins. Most of these had resisted routine measures of treatment and were of a chronic, indolent type. Treatment with cysteine was used alone or in conjunction with measures concerned with relieving the static edema, such as supportive bandages, or obliterating injections into the varicose veins. In dressings of cysteine, when applied to ulcers about the lower parts of the legs, firm pressure was usually exerted by means of a soft rubber sponge incorporated in the elastic bandage that was wound from foot to knee. In a number of cases of bilateral involvement the following procedure was employed. The basic treatment of the ulcers of both legs was the same throughout, but for a time cysteine would be added for treatment of the ulcers on one leg, then the cysteine would be omitted in treatment of that leg and applied in treatment of the other. Whenever cysteine was employed, the ulcers to which it was applied advanced toward healing more rapidly than

those on the other leg. Thus, a system of alternate control allowed adequate evaluation of the effect of cysteine.

Certain traumatic ulcers, variously situated, were treated with cysteine. The following case is illustrative.

CASE 1—A girl, aged 18, sustained a deep laceration of the posterior aspect of the upper part of the right arm, the result of an automobile accident, July 4, 1930. After preliminary debridement, the fascia and skin were approximated by silk and dermal sutures. About half of the incision failed to heal, and a raw necrotic wound remained. When treatment by cysteine was begun, August 4, there was a large ulcer, fairly clean representing a denuded area measuring about 5 by 15 cm. Within twenty-four hours there was evident a striking degree of stimulation of the hitherto dormant granulation tissue and of the epithelial margins of the wound. Cysteine was used intermittently for three or four days at a time, alternating with ointments of weak balsam of Peru for a similar time. Within twenty-one days epithelization was complete (figs 1, 2 and 3). The epithelium was rather thin probably because of its rapid growth, after six weeks a small vesicle appeared, and a slight break of the covering of the surface. Cysteine was applied for four or five days and healing was complete. There was no further trouble.

In postoperative wounds, the stimulating properties of cysteine were valuable. One such case is illustrated by the following report.

CASE 2—A man, aged 45, was seen thirty-seven days after posterior gastro-enterostomy for chronic duodenal ulcer. The abdominal wound had healed except for a residual sinus 2 cm.

Fig 1 (case 1)—Traumatic ulcer of the upper part of the right arm before treatment

long 1 cm wide and 2 cm deep. There was considerable seropurulent exudate and the granulation tissues were pale. A probe revealed the cutaneous margins to be undermined about 2 cm in all directions. Routine measures, including treatment by stimulants and by ultraviolet rays from the mercury vapor arc in quartz for three weeks, had brought about little change in the size or appearance of the wound. Within forty-eight hours after application of dressings of cysteine were begun, drainage practically ceased, granulations became red and exuberant, and within fourteen days healing was complete.

In the care of decubital and trophic ulcers we found cysteine to be useful, although of limited application. In these types of intractable ulcerations, treatment by local measures is usually handicapped by disturbances of the general health. However, there was a certain amount of stimulation of granulation tissue following application of cysteine, and secondary bacterial overgrowth was inhibited. In several cases of decubital

ulcers, cysteine applied at intervals apparently shortened the period of hospitalization

In carbuncles, after suppuration, cysteine is efficient in promoting the growth of granulation tissue. There is usually more prompt sloughing of the necrotic sphacelus and a cleaner base when cysteine is used. In three instances of extensive carbuncle of the neck and back, such treatment contributed to the earlier and successful use of skin grafts, and to healing of the wounds with a minimum of deformity.

Fig. 2 (case 1)—Appearance of ulcer treated by cysteine after four teen days

In extensively denuded surfaces, such as occur in burns from gasoline, the securing of satisfactory epithelization without disabling deformity presents a problem. If multiple pinch skin grafts are applied to the denuded surface, there is a higher percentage of successful "takes" when cysteine is used. The dressings are applied to the granulating surface before grafting and to the grafted regions at intervals following, using perforated protective strips to prevent mechanical displacement of the grafts. Case 3 is an example.

CASE 3—A man aged 24 was severely burned by an explosion of gasoline, Aug. 30, 1929. He was admitted to the Mayo Clinic in the spring of 1930 critically ill with legs and hands covered with old burns of second degree. Treatment was carried out by prolonged immersion in warm baths and other supportive measures. The patient was in poor condition and frequent transfusions of blood were given. Progress was slow, and was interrupted by febrile periods which probably were due to the secondary infection in the extensively denuded regions. By the middle of July there was sufficient general improvement to warrant application of stimulating measures to the ulcers of the legs. Cysteine was applied to the left thigh as a trial with prompt stimulation of the granulation tissues resulting. Within from ten to fourteen days a few islands of epithelium had appeared and drainage from the treated surface was at a minimum. Cysteine was used in various portions of the wounds as the patient's condition permitted the use of wet dressings. In December seventy-five pinch grafts were applied with unsuccessful results. This procedure was repeated and cysteine was applied over half of the grafts. There was decided improvement in the region to which cysteine had been applied. Granulations were richer and the grafts were more successful than in the untreated portions. In this fashion the right leg became completely healed by January, 1931. In March 120 grafts were made to the left leg posteriorly and anteriorly. Cysteine was applied over perforated strips smeared with petrolatum placed over the fresh grafts. Treatment by stimulation was continued intermittently until May 11, at which time healing was almost complete. The patient was dismissed in August, 1931. Examination one year later revealed

an excellent epithelial covering with little deformity. This case is a good example of the usefulness of cysteine in clearing secondary infection to permit of skin grafting in extensive wounds.

In such conditions as roentgen ulcers, one would expect little benefit from stimulating preparations. However, we have observed that in such wounds if residua of epitheliomatous degeneration have been removed by cautery, healing is perhaps accelerated when cysteine is used at intervals, especially when skin grafts are a part of the reconstructive procedure.

Several scrofulous sinuses, Bazin ulcers and nodulo-ulcerative syphilids were somewhat cleared of secondary infection by dressings of cysteine, without, of course, any effect on the underlying constitutional disturbance.

Cysteine was used without appreciable effect, in a few cases of miscellaneous cutaneous lesions, psoriasis, pustular psoriasis, lichen simplex chronicus and lichen planus.

COMMENT

Two decided changes were brought about in ulcers following the use of cysteine: first, stimulation of granulation tissue and epithelial proliferation, and second, diminution of drainage, with clearing of secondary infection. In the entire group of 200 cases of ulcer treated with cysteine, there was decided stimulation to healing in 50 per cent, in 25 per cent, the beneficial effect was promising, in the remainder, the results were desultory. In only three or four instances was it necessary to discontinue the treatment because of the discomfort and irritation provoked at the periphery of the ulcers under treatment. Best results were obtained when cysteine was used in alternation with periods of dry, bland treatment, each of two or three days' duration. It was observed that the stimulating properties

Fig. 3 (case 1)—Appearance of ulcer after twenty-one days complete epithelization

of cysteine were less pronounced when healing was near completion. Many of the lesions progressed rapidly until about from 80 to 90 per cent of the area was covered with epithelium at which point stimulation by cysteine ceased.

The inhibition of bacterial growth by cysteine is difficult to explain. Hammett and Reinman found in wounds treated by thioglucose that there was decided bacterial overgrowth. In fact Welsh² in unpublished

² Welsh, A. L. Personal communication to the authors.

experiments on cysteine *in vitro*, found that in concentration of sulphur of 1:20,000 there was a decided stimulus to growth of certain organisms, the cocci in particular. The cleanness of wounds under treatment by cysteine may possibly be attributed to the wet dressings or perhaps to the elaboration of unknown products by cells of the epithelium or of the granulation tissue in the process of rapid healing.

The use of this compound, in conjunction with multiple pinch grafts in extensive ulceration, gave satisfactory results. There was a larger number of successful "takes" in areas where cysteine was used than in areas treated for purposes of control by routine methods. In certain instances where grafting had been unsuccessful on previous attempts, there was a better average of "takes" following the use of cysteine. It was essential, of course, preliminary to the laying of grafts by various methods that the bed of granulation tissue should be vascular and slightly exuberant, to which end the use of cysteine was particularly applicable.

From the practical standpoint, in the treatment of ulcers in general the use of cysteine is advocated, not as a substitute for the well established procedures in common use, but as an adjunct to the treatment of more resistant cases.

Cysteine is active only in its reduced, sulphhydryl form (SH-). After oxidation to the disulphide cystine (S-S), the compound is inert. For this reason it is necessary to emphasize the need for freshly prepared material applied at frequent intervals. We were unable to demonstrate in the examination of old dressings whether there was oxidation of the compound beyond the disulphide stage. Quantitative studies as to the amount of cysteine absorbed in various stages of healing are as yet incomplete.

SUMMARY AND CONCLUSIONS

The observation of Hammett and Reimann of the stimulating properties of certain sulphhydryl-containing compounds is confirmed.

Cysteine, a naturally occurring sulphhydryl containing amino-acid, obtained by the reduction of the disulphide cystine, a product of the hydrolysis of wool or of the hair of man, is capable of stimulating granulation tissue and epithelium. When applied to cutaneous wounds and ulcers bacterial growth is inhibited.

This report brings out the practical value of cysteine as used in the Mayo Clinic in the last three years in more than 200 cases of a variety of types of cutaneous ulcer.

ABSTRACT OF DISCUSSION

DR. JOSEPH V. KLAUDER, Philadelphia. The story of sulphur, one of the oldest remedies known to man, is of particular interest to the dermatologist. As an antiparasitic and employed in the bath, sulphur was one of the earliest drugs used in the treatment of skin diseases and is today one of the most important agents employed by the dermatologist. The dermatologist is much concerned with keratin, which is the chief constituent of epidermal tissue. Keratin is peculiar in that it has a high sulphur content, the sulphur being present almost entirely in the form of the amino-acid cystine. No other protein is so high in cystine as the keratin of human hair. It would appear, therefore, that the metabolism of sulphur probably plays an important role in the development and growth of epidermal tissue. Attention is now being directed to a new sulphur preparation, one containing the sulphhydryl group. Hammett, Reimann and their co-workers of the Research Institute of theankenau Hospital, Philadelphia, conducted studies to determine the chemical difference between the nucleus of a cell in mitosis and the nucleus of a cell in the resting condition.

It was determined that whatever other chemical differences there are, the most essential is a rearrangement of the sulphur in the molecules, so that this element appears in the chemical group sulphhydryl and that this group is a stimulant to cell multiplication and that the partially oxidized derivatives thereof are retardative. Among several sulphhydryl preparations studied by Reimann to stimulate wound healing, parathiocresol was selected. He observed that thioglucose favored bacterial growth and that thiophenol was too irritating. Drs. Brunsting and Simonsen have shown that cysteine may advantageously be employed. The advantage of this preparation is that it is less irritating than parathiocresol. Its disadvantages are that it is somewhat more expensive and it is more rapidly oxidized forming cystine, which is inert. However, all sulphhydryl containing preparations probably undergo slow oxidation and must therefore be employed fresh. Caution should be exercised in not applying sulphhydryl-containing preparations to malignant ulcerations and probably not to so-called premalignant lesions since they may be stimulated to malignant change. In this category I would include ulcers, part of an x-ray dermatitis. For the same reason, prolonged application of sulphhydryl containing preparations to benign epithelial tumors, such as warts, papillomas and molluscum contagiosum, and chronic ulcers, particularly in a person of the cancer age is theoretically at least contraindicated. Another use of sulphhydryl preparations is to cause thickening of the skin over healed ulcers, burns and wounds. Reimann employed parathiocresol at over 0.25 per cent in an anhydrous wool fat base. He advised its application three times a week until the desired result is obtained. Cysteine is probably too unstable for this purpose.

DR. JOHN H. STOKES, Philadelphia. I did not hear the entire paper but I wish to commend the sulphhydryl preparations in the treatment of bed sores. They are capable of transforming the misery to which these patients are subjected into comparative comfort. I have in mind particularly the spinal paralytic bed sores. A patient who had almost sloughed away his entire sacral area was relieved of pain and obtained a marvelous effect from it on the bed sores. The cheaper preparations in spite of their bad odor in the mass, can be so handled by skillful packing and attention as to avoid this objection and the tendency to skin irritation likewise.

DR. M. F. ENGMAN, JR., St. Louis. Cysteine in small quantities is used in culture material. I have been attempting to grow a typical form of the bottle bacillus which is very difficult, and after a great deal of trouble we obtained a few cultures in which I thought I had the bottle bacillus. There was never a pure culture but cysteine added to the medium improved the growth slightly in what way I do not know. There is a definite metabolic action involved. Perhaps the primitive types of cells in general will improve when cysteine is in their vicinity and assists in their nourishment.

DR. LOUIS A. BRUNSTING, Rochester, Minn. Dr. Klauder brought up the point of the possible stimulating effect of these preparations on new growths. In our series of over 200 cases biopsies were made in all suspicious cases and all evidences of neoplasms were excised and in some of these cysteine was used to promote the healing of the cauterized base. I will endorse the remarks of Dr. Stokes in regard to the value of these preparations in the treatment of decubitus, aside from the disadvantage of the use of wet dressings in the usually affected sites. The rate of healing was about the same under thiocresol or cysteine, although there was more apt to be irritation of the skin surrounding the ulcers under treatment by thiocresol than by cysteine.

The Basal Ganglia.—The basal ganglia comprise the following masses of gray matter: (1) optic thalamus, (2) lenticular nucleus, (3) caudate nucleus, (4) red nucleus. The lenticular nucleus and the caudate nucleus together form the corpus striatum. The first three are grouped around the internal capsule. The red nucleus is situated below the optic thalamus in the upper part of the midbrain. The lenticular nucleus is divided into an outer portion (the putamen) and an inner portion (the globus pallidus).—Steen, R. E. A New View of the Function of the Corpus Striatum, *Irish J. M. Soc.* June 1931, p. 258.

FACIAL DIPLEGIA IN LYMPHATIC
LEUKEMIA

PAUL H. GARVEY, MD

AND

JOHN S. LAWRENCE, MD

ROCHESTER, N. Y.

Bilateral paralysis of the facial nerves is rather uncommon. It is usually associated with infections of the nervous system, such as polyneuritis and gummatous basal meningitis. A leukemic origin of the disorder is extraordinary. In view of the infrequency of leukemia as a cause of facial diplegia, we have thought it worth while to report the clinical and pathologic observations in a patient who presented this picture. We have included in this report the clinical data in two other cases of acute leukemia in which a unilateral facial paralysis occurred.

REPORT OF CASES

CASE 1—Clinical History.—L. M., a housewife, aged 46, was admitted to the Rochester Municipal Hospital, Feb. 3, 1932. She complained of paralysis of both sides of the face, loss of the sense of taste, headache, dizziness and nausea. Her present illness began on Jan. 6, 1932, with an attack of dizziness which was followed by nausea and vomiting. The following day she complained of weakness and dizziness and was confined to bed for one week. During this time, she had a fever which ranged between 101 and 103 F. The paralysis of the right side of the face developed ten days before admission to the hospital and that of the left side two days before entry. Additional symptoms at the onset of the facial paralysis were severe throbbing headache, sore throat and tinnitus in the left ear. The past history was irrelevant.

Physical Examination.—She was well nourished and did not appear acutely ill. The temperature (rectal) was 38 C (100.4 F) and the pulse rate 100. Respirations were 20. The blood pressure was 150 systolic and 90 diastolic. The skin and mucous membranes showed no evidence of anemia. The tonsils were enlarged and covered with a grayish-white exudate. Numerous small purpuric spots could be seen over the surface of the tonsils. The cervical glands were slightly enlarged and tender to palpation. Examination of the heart and lungs yielded negative results. The spleen and liver were not palpable.

Neurologic Examination.—The face was expressionless, owing to a bilateral facial paralysis of the peripheral type (fig. 1). The patient could not wrinkle the forehead, retract the corners of the mouth or completely close the eyes. The inability to move the lips resulted in some impairment of speech. The sense of taste was lost over the anterior two thirds of the tongue but was well preserved over the posterior portion. The facial muscles on both sides failed to react to faradic current. There was some nystagmus on looking to the left. Hearing was slightly impaired on the left side. The cranial nerves were otherwise normal. Ophthalmoscopic examination gave negative results. A neurologic survey of the extremities revealed no abnormalities.

On admission the hemoglobin was 85 per cent (Sahli), the red blood cell count was 5,050,000 and the white blood cell count was 14,750 per cubic millimeter. The differential count showed polymorphonuclear neutrophils 70 per cent, lymphocytes 25 per cent, monocytes 3 per cent, eosinophils 1 per cent and basophils 1 per cent. Platelets appeared in normal abundance. A lumbar puncture yielded a clear colorless spinal fluid under pressure of 190 mm. of water. The spinal fluid contained 5 cells per cubic millimeter and the Pandy test was negative. The Wassermann tests of the blood and spinal fluid were negative. Culture of the throat for Klebs-Loeffler bacilli was negative. The urine was normal.

Clinical Course.—On February 12, or nine days after admission, the patient developed a slight fever. At the same time purpuric spots were noticed over the forearms. The white blood cell count on this date was 52,100 per cubic millimeter. A differential count at this time was polymorphonuclear neutrophils, 19 per cent and small lymphocytes, 73 per cent. The bleeding time was three and a half minutes. On February 16 the cervical glands were considerably larger and a few glands could be felt in the left axilla and right inguinal region. Purpuric spots were widely distributed over the body. The spleen and the liver were not palpably enlarged. The facial paralysis remained unchanged. The hemoglobin and red blood cell count fell to 80 per cent and 4,670,000 respectively. The leukocyte count rose to 144,400 per cubic millimeter. A differential count with supravital neutral red technique showed neutrophils, 10 per cent, myelocytes B, 0.5 per cent, basophils 1 per cent, eosinophils 0.5 per cent, small lymphocytes 81 per cent, intermediate lymphocytes, 4 per cent, monocytes, 1 per cent, degenerated forms, 2 per cent. Examination of two fixed stained smears revealed only 5 platelets. An oxydase differential count on 200 cells showed 7.5 per cent positive and 92.5 per cent negative. Bleeding time was eight and a half minutes. Two days later the patient began to bleed profusely from the nose. The glandular enlargement had increased. Albumin and red blood cells appeared in the urine. The neurologic signs remained unchanged. On February 25, a blood count showed 35 per cent hemoglobin, 2,080,000 red blood cells and 61,600 white blood cells per cubic millimeter. Death occurred on the following day, approximately seven weeks after the onset of the illness. Necropsy was obtained.

Gross Anatomy.—There were numerous purpuric spots in the skin of the trunk and extremities. The mucous membranes and serous surfaces of the thoracic and abdominal cavities also showed small hemorrhages. The right pleural and pericardial cavities each contained about 200 cc. of bloody fluid. There was generalized enlargement of the superficial and deep lymph glands. The spleen and the liver were not enlarged.

The meninges appeared normal except for many petechial hemorrhages in the pia-arachnoid over the convexity of the brain. The cranial nerves showed no macroscopic changes. The seventh and eighth nerves were traced through the petrous portion of the temporal bones, and no gross abnormality was found. On section the brain and spinal cord were normal.

Microscopic Anatomy.—Sections taken from representative areas of both hemispheres and stained with thionine and hematoxylin-eosin showed no structural alteration except for an occasional vessel with a small collection of lymphocytes in the perivascular space. In some areas infiltration with lymphoid cells occurred in both the cerebral meninges and the walls of the meningeal vessels. As a result of the accumulation of these cells in the walls of the vessels, there was weakening with consequent hemorrhage. Sections of the brain stem showed no evidence of infiltration or hemorrhages. The cells forming the nuclei of the seventh nerves showed marked structural alteration of the type which occurs following injury to a peripheral nerve. Many of the cells were smaller and stained poorly. The nucleus and Nissl granules had disappeared from many of the cells, and in others the nucleus was eccentrically placed (fig. 2). The third and seventh pairs of cranial nerves were unfortunately the only ones available for microscopic study. Sections taken from the seventh nerves showed diffuse infiltration with lymphoid elements (fig. 3). The cells were found between individual fibers especially in the peripheral portion. The perineural tissues were also heavily infiltrated with lymphoid cells and red blood cells. The cellular infiltration of the right facial nerve was more extensive than that of the left. Sections of the facial nerves stained by the Marchi method showed degeneration of the nerve fibers. This was likewise more pronounced in the right facial nerve. Leukemic infiltrations were also found in both oculomotor nerves. The spinal cord was normal except for a few minute hemorrhages. Marchi preparations showed no evidence of degeneration of the fiber tracts. The spinal meninges were also infiltrated with lymphocytes. A few of the spinal nerves showed small collections of lymphocytes in the perineural spaces. The walls of some of the meningeal vessels were infiltrated with lymphocytes.

From the Department of Medicine, University of Rochester School of Medicine, and the Medical Clinic of the Strong Memorial and Rochester Municipal Hospitals.

Read before the Section on Nervous and Mental Diseases at the Eighty-first Annual Session of the American Medical Association, Milwaukee, June 14, 1939.

Comment—The clinical picture on admission suggested strongly follicular tonsillitis complicated by cranial nerve neuritis. The appearance of the tonsils at this time, however, was atypical, since numerous small purpuric areas were present. This should always suggest the possibility of a leukemic process. The fact that the blood picture at this time revealed nothing other

Fig 1 (case 1)—Bilateral facial palsy showing the expressionless face

than a neutrophilic leukocytosis made the diagnosis more difficult. Later when the blood took on the characteristics of lymphatic leukemia the diagnosis was readily established. It is of distinct interest that infiltration of the cranial nerves occurred at a period when there was no increase in the number of lymphocytes in the peripheral blood. This demonstrates that it is possible to have marked increases in the number of cells in local-

ized areas of the body without having their numbers augmented in the peripheral blood.

CASE 2—Clinical History—J. B., a 65 year old, married farmer was first seen in the medical outpatient department, Dec 8, 1932. He complained of pain in the right arm, double vision, dizziness and night sweats. The onset was in September, 1932, and was characterized by severe shooting pains in the left shoulder which radiated down the arm. These pains persisted for several weeks and were followed by pain of a similar type in the right arm. About two and a half months after the onset, he complained of double vision and a "staggering spell" during which he noticed a tendency to fall toward the right. The following day his wife noticed an internal strabismus in his left eye. There was no history of tinnitus or headache. Since the onset of his illness he has had frequent night sweats, weakness and loss of weight. The past history was irrelevant.

Examination—The patient was well nourished and did not appear acutely ill. The temperature, pulse and respirations were normal. The general physical examination showed evidence of cardiac enlargement. The blood pressure was 160 systolic and 85 diastolic. There was no enlargement of the superficial lymph glands, liver or spleen. A large ecchymotic area was present in the skin of the right flank. The neurologic examination gave negative results except for paralysis of the left abducens nerve, which was unaccompanied by paralysis of conjugate deviation of the eyes. The blood count was as follows: hemoglobin 82 per cent (Sahli), red blood cells, 4,350,000 per cubic millimeter, leukocytes 15,300 per cubic millimeter, differential count 37 per cent polymorphonuclear neutrophils, 2 per cent eosinophils, 57 per cent lymphocytes and 4 per cent monocytes. The smear showed definite diminution in the number of platelets. The urine contained a small amount of albumin. The Wassermann test of the blood was negative.

Course—On December 13 he was again examined in the outpatient department. He complained of the same symptoms which were recorded at the time of his initial visit. During the intervening five days he developed some difficulty in eating. Examination on this date revealed a complete right facial paralysis of the peripheral type, left abducens paralysis and slight evidence of weakness of the right abducens nerve (fig 4). He was admitted to the hospital for further study with a tentative diagnosis of lymphatic leukemia.

On admission, December 15, his physical status was unchanged, except for slight enlargement of the cervical and axillary gland. A few petechiae were observed on the soft palate. The white blood cell count rose from 20,000 on the day of admission to 48,000 on the day of discharge, nine days later. Supravital and fixed preparations (including oxydase stain) showed 92 per cent lymphocytes of the small and intermediate types. The spinal fluid contained 23 lymphocytes per cubic millimeter. The Wassermann test of the spinal fluid was negative. The blood sugar was 71 mg per hundred cubic centimeters, the nonprotein nitrogen, 50 mg, and the blood uric acid, 66 mg. The basal metabolic rate was plus 74.

The diagnosis of lymphatic leukemia was established on the basis of the clinical and laboratory data. The patient received three high voltage roentgen treatments across the base of the skull and one over the spleen. On December 21 slight ptosis and limitation of inward movement of the left eye were present. The paralysis of the left sixth nerve and weakness of the right sixth nerve remained unchanged. The right facial paralysis showed no evidence of clearing. The patient was discharged from the hospital December 24, unimproved, and died at home ten days later. A communication from his wife stated that he did not develop paralysis of the left side of the face before death.

Comment—The onset of the disease in this case was likewise characterized by a predominance of symptoms and signs referable to the nervous system. The cranial nerve palsies developed when the leukocyte count was relatively low and few symptoms of a constitutional disease were present. Studies of the blood in this case were helpful in arriving at an early diagnosis. It is impossible from the clinical observations in this patient to determine whether the cranial nerve palsies were the result of nuclear or peripheral nerve involvement. The absence of weakness or paralysis of conjugate deviation of the eyes suggests a peripheral location of the lesion.

Fig 2 (case 1)—Structural alteration of the cells of the left facial nucleus

CASE 3—Clinical History—J. V., a 21 year old truck driver was admitted to the Rochester Municipal Hospital in a critical condition. He complained of bleeding and weakness. His present illness began ten weeks prior to admission with a severe nosebleed. The following day there was a large bluish purple discoloration over the right side of the face with marked edema and partial closure of the right eyelids. He was admitted to another hospital in the city on May 31, where he remained

six weeks. A diagnosis of lymphatic leukemia was made, and he received two blood transfusions and high voltage roentgen treatments over the neck and spleen. On his admission to that institution examination of the blood showed a marked secondary anemia, and the leukocytes numbered 109,000 per cubic millimeter. On July 5 he developed a paralysis of the right side of the face. The past history was irrelevant.

Fig 3 (case 1)—Infiltration of the right facial nerve with lymphoid cells

Physical Examination—He was pale and emaciated. The temperature was 40 C (104 F) and the pulse rate 120 respirations were 30. He was mentally clear. The mucous membranes of the mouth showed many small hemorrhages and there was marked inflammation of the gums. The cervical, axillary and inguinal glands were enlarged. The spleen was palpable. Examination of the heart and lungs gave negative results. The blood pressure was 110 systolic and 0 diastolic. The neurologic examination gave negative results except for a right facial paralysis of the peripheral type.

The blood count on admission showed a pronounced secondary anemia with 1,440,000 white blood cells per cubic millimeter. The predominant cells in the smear were lymphoblasts and lymphocytes. Platelets were decreased in number. Urinalysis and the Wassermann test of the blood gave negative results.

Course—The patient's condition became progressively worse and the white blood cell count fell to 4,500 per cubic millimeter on the day of his death, six days after admission. Autopsy was not obtained.

Comment—This case differs somewhat from the two previously described in that the facial paralysis appeared six weeks after the clinical picture of leukemia was well established. Hemorrhagic phenomena in the skin and mucous membranes were prominent symptoms before the paralysis occurred. The nature of the lesion involving the seventh nerve was undetermined but nevertheless it seems justifiable to attribute it to the changes found in the cranial nerves in cases of leukemia.

COMMENT

In 1926 Fried¹ reported the pathologic changes in the brain in a case of lymphatic leukemia and reviewed from the literature the neuropathologic observations in thirty cases. In seven of these cases there was

involvement of the cranial nerves, and in four a bilateral facial paralysis occurred. In addition to those cases quoted by Fried similar cases have been reported by Moore,² Laroche and Chatelin,³ Trommer and Wohlwill,⁴ Spangenberg⁵ and Howell and Gough.⁶ In the majority of these cases, in which pathologic examination was done, the leukemic changes were found in the nerves or their sheaths. The paralysis and ultimate degeneration of the nerves were ascribed to infiltration with lymphoid cells and hemorrhages. Howell and Gough have furnished an excellent example of cranial nerve paralysis due to nuclear involvement. Although they found slight leukemic infiltration of the nerve sheaths the chief pathologic changes were found in the nuclear regions and consisted of lymphomas, capillary thrombosis and perivascular accumulation of lymphocytes.

It is interesting to note that the cases in which facial diplegia occurred were all of the lymphatic type and, with one exception, were cases of acute leukemia. Cranial nerve palsies are much less frequent in the course of myelogenous leukemia. Trommer and Wohlwill reported the case of a 46 year old laborer with severe trigeminal neuralgia, which was not relieved by the extraction of teeth. It was later discovered that he had myelogenous leukemia.

The frequency of involvement of the facial nerves is not surprising when one considers the anatomic circumstances which make the facial nerves particularly vulnerable. Slight edema of the facial nerve in its intracranial portion may result in considerable functional disturbance. In our first case the infiltration of the oculomotor nerves was almost as extensive as that found in the facial nerves, yet there was no evidence of dysfunction during life. Although the facial nerve is given special mention in individual case reports, it must be recognized that other cranial nerves may show the same histologic changes. It is a well established clinical fact that leukemia is a relatively common cause of that group of symptoms which is designated as Meme's symptom complex. This syndrome is usually ascribed to hemorrhages in the labyrinth but may be due to infiltration of the eighth nerves with lymphoid

clements similar to that in the case described by Trommer and Wohlwill

While the number of clinical and pathologic observations on cranial nerve involvement in leukemia is small, we believe that if the cranial nerves were examined pathologically in all cases of leukemia the incidence of involvement would be much higher than is generally supposed. It is important, therefore, to consider the possibility of leukemia in all cases of unexplained cranial nerve paralysis, particularly in those cases in which there is clinical evidence of unilateral or bilateral paralysis of the seventh or eighth nerves.

If one bears in mind the possibility of leukemia as a cause of cranial nerve paralysis, it will be only the exceptional case that may offer difficulty in diagnosis. A facial diplegia of leukemic origin with perhaps some paresthesia in the extremities, owing to infiltration of the spinal nerve roots, may be confused with that form of infectious polyneuritis in which a bilateral facial paralysis is a special feature. The presence of glandular enlargement, hemorrhagic phenomena in the skin and mucous membranes and leukemic blood changes should lead to the correct diagnosis. The same criteria are necessary in differentiating the condition from facial diplegia due to syphilis. In Howell and Gough's case the patient had a positive Wassermann test but necropsy disclosed the leukemic nature of the paralysis.

SUMMARY

Patients suffering from leukemia, especially the acute type, may have paralysis of the cranial nerves owing to leukemic infiltrations and hemorrhages in the nerves or their nuclei. The facial nerves are frequently affected. In three cases of acute lymphatic leukemia reported, bilateral facial paralysis occurred in case 1 and unilateral facial paralysis in cases 2 and 3.

ABSTRACT OF DISCUSSION

DR. GEORGE B. HASSIN, Chicago: Drs. Garvey and Lawrence gave an excellent description of the peripheral nerve changes. They show infiltrative phenomena of perineuritis and endoneuritis combined with degenerative nerve changes ordinarily seen in peripheral neuritis. The infiltrations and the changes in the axons and myelin have no relationship; that is, the degenerative nerve changes are not caused by the infiltrations. The two are independent phenomena due to the same cause, an infection or, more probably, an intoxication. The ganglion cell changes of the seventh nerve demonstrated by the authors are secondary (axonal reaction).

DR. R. H. JAFFE, Chicago: In the modern literature on leukemia there is the tendency to consider it as belonging to the malignant tumors. I do not think, however, that this assumption is warranted since fundamental differences exist between leukemia and malignant tumors. While in malignant tumors metastases develop from the primary tumor by the implantation of cells derived from the primary tumor, the leukemic infiltrations develop locally from the undifferentiated mesenchyma, which is widely distributed in the body and is found especially about the smaller blood vessels. Normally when irritated this undifferentiated mesenchyma gives rise to free histiocytes and probably also to lymphocytes and plasma cells. In leukemia there is a fundamental change in the reactivity of the mesenchyma in that even a slight physiologic stimulation induces an abundant proliferation of the perivascular cells, which may differentiate into lymphoid or myeloid tissue. Thus the leukemic tissue develops locally and not by implantation from a primary focus. The organs most commonly affected by the leukemic cell proliferation are the bone marrow, spleen, lymph nodes, liver, lymphatic tissue of the digestive tract, and the kidneys. In some instances the proliferations are more generalized, involving also the heart, suprarenals, thyroid

lungs, skin and other structures. It is interesting to see how the mesenchyma of the nervous system reacts in cases of leukemia and it seems to me that it does not differ from the mesenchyma of the other regions of the body. The presence of toxic changes in the brain in cases of acute leukemia supports my conception that there exist intimate relations between infection and leukemia. There is, perhaps, an inherited or acquired abnormal irritability of the mesenchyma, the leukemic tendency of which becomes manifest under the influence of a variety of toxic or infectious causes.

DR. TOM B. THROCKMORTON, Des Moines, Iowa: I should like to know how long there may be evidence of peripheral cranial nerve involvement before leukemic changes in the blood become manifest, or do the blood changes always precede the paralytic symptoms? I have in mind an instance of an isolated third nerve paralysis occurring in a middle aged man who otherwise seems to be perfectly healthy. No explanation so far, has satisfactorily accounted for the cause of the paralysis. The presentation of this paper opens up a new possibility and I wonder whether it may be possible that my patient is manifesting the early evidence of leukemic paralysis before blood changes of the disease are evident, just as one often sees patients with a combined cord lesion due to pernicious anemia, in whom the blood changes are slight or entirely absent.

DR. JOHN L. GARVEY, Milwaukee: In answer to the last question the first patient had a white count of 14,000 and there was no disturbance of the differential formula. One of the other cases I recall a case of double abducens and double facial paralysis described by Spangenberg presented a white count of 9,000. The differential count in this case revealed a lymphocytosis.

UNUSUAL EXPERIENCE WITH AMEBIC DYSENTERY

IN AN AVERAGE HOSPITAL OF A NORTHERN STATE,
WITH REPORT OF NINE CASES ORIGINATING IN CHICAGO

KANO IKEDA, M.D.

ST. PAUL

The news of a serious outbreak of amebic dysentery in Chicago during the summer contained in the press dispatch of Nov. 10, 1933, immediately confirmed the belief that all the five cases then presenting the disease which had been recognized in this hospital during the preceding three weeks, had probably been contracted while the patients were visiting in that city. Not until the publication of the articles¹ on amebiasis dealing specifically with this outbreak, in the November 18 issue of THE JOURNAL, was the seriousness of the situation with its widespread danger affecting the whole nation fully appreciated. While my associates and I did not, from the onset of our experience, minimize the far reaching epidemiologic significance of amebiasis as a result of the suspected outbreak in Chicago, we were more impressed with the comparatively large number of cases we had been able to recognize during this short period, when apparently no other cases of amebic dysentery had been reported from this locality.

Indeed, so much interest had already been aroused that on November 7 we devoted the entire evening to the subject of amebiasis with autopsy report at our monthly staff meeting. It became clearly pertinent to

Read in part before the Ramsey County Medical Society Nov. 29, 1933.

question whether some of the cases showing intestinal disorders, at least among those who had visited in Chicago during the summer, may not in reality have been cases of amebic dysentery which physicians failed to suspect or recognize. That such would seem to have been the fact has since been amply substantiated by reports from various parts of the country, notably the report by Lund and Ingham² in a recent issue of *THE JOURNAL*.

The Chicago epidemic, resulting in a nation-wide fresh dissemination of this infection, has awakened unusual interest among practicing physicians. The present report of nine cases that came under observation in the past six weeks with some of the features unique in my experience, is deemed timely.

INCIDENCE IN MINNESOTA

While a number of articles have been written calling the attention of the profession to the relative frequency of this infection in the Northern states, only sixty-seven cases were reported to the Minnesota State Board of Health in the sixteen-year period ended Dec 31, 1932, from civil practice, with thirty-two deaths, an incidence of four cases a year with a 50 per cent mortality, 476 other cases were recorded during the same period from the United States veterans' hospitals and 120 cases at the Mayo Clinic, among the out of state patients from 1926 to 1932, inclusive. Only seven cases were reported from St. Paul from 1917 to 1927, all of which were fatal. No cases were reported from this city from 1928 to 1932 inclusive. Only ten cases were reported from Minneapolis from 1917 to 1932, inclusive. This would seem to indicate that physicians either fail to recognize this condition in many instances or neglect to report the occurrence to the health authorities when diagnosed. That the endemic occurrence of this infection has been rare in Minnesota may be partly inferred from my own limited experience of the past fifteen years, representing however, a fair cross section of hospital laboratory practice in the Twin Cities, in which only two or three cases (or less than 1 per cent of the stools examined for ova and parasites) of intestinal amebiasis, usually of the chronic or recurrent type, have been seen annually. This may be said to conform roughly to the experience of the Chicago Board of Health, with only eighteen cases of amebiasis a year since 1930.

It was therefore quite unusual to discover rather unexpectedly two cases of amebic dysentery within a period of a few days. As the source of infection in the first case had already been fairly definitely traced to Chicago our suspicion in the second case was soon confirmed when the patient was found to have been a frequent visitor to Chicago during the summer. Chicago as a common source of amebic infection was now more than a probability and it was freely predicted that more cases of dysentery would be found among those who had visited the world's fair. Our prediction was soon substantiated by finding three additional cases all traceable to that city within another ten days, making a total of five cases of amebic dysentery in less than twenty days, a unique experience in ordinary times in a private hospital of an average capacity in this part of the country. We have since diagnosed four more cases making a total of nine cases in a period of approximately six weeks.

In the face of a serious outbreak such as has occurred during the past four months, it may be estimated that out of those who actually become exposed to this infection, that is, out of those who ingested cysts of *Endamoeba histolytica*, a small number may entirely escape transmission, another equally small number may develop the symptoms of acute dysentery requiring immediate medical attention and the remainder, representing fully more than 50 per cent, though infected may probably show little or no clinical symptoms of dysentery or serious abdominal distress. It is this last group, constituting many thousands of Chicago visitors from all over the country during the summer months, that may become a great menace to public health, along with the clinical cases that are never diagnosed.

REPORT OF CASES

An analysis of these nine cases brings out several unique and atypical features, which may easily be confused with other intestinal disorders and may prove

Fig 1—Appearance of colon in case 1 showing narrowing of the lumen irregular outline (filling defect) induration of the wall involving the cecum and part of the ascending colon there is apparent shortening or contraction of the involved area also a wide open ileocecal valve

not only interesting but instructive in the differential diagnosis of this unfamiliar disease. The possibility of intestinal amebiasis among those who may consult the physician with vague abdominal distress or gastrointestinal upsets as well as with acute abdominal symptoms is once more emphasized, in the light of our experience with these nine cases. None of the patients, it should be noted, had ever experienced similar attacks before.

CASE 1 (Drs H E Hullsiek and C N Hensel)—C B a man aged 59 a surgeon on his way home from an extended vacation trip through the Pacific West was forced to stop off at St. Paul on account of rectal discomfort. He was admitted to the hospital October 13 as an outpatient for proctoscopic examination and biopsy from a rectal lesion which had been observed at the office of the attending physician. The patient gave a six weeks history of rectal discomfort associated with periods of diarrhea. The first attack of diarrhea was experienced a day after his arrival at Yellowstone National Park from

1. I. C. C. and Ingham, T. R. For Fatal Cases of U. S. 10. J. Am. Med. Assoc. 101: 1000 (Nov. 2, 1933).

Chicago, September 1, and was thought to be due to water and foods at the park. This lasted three days. The stools were clay colored and there was a trace of gross blood and mucus. This he attributed to straining at stool. September 8, he took a laxative, which made him feel much better. The stools appeared normal. There was a recurrence of diarrhea, September 11. This was associated with vague pains in the rectal

Fig 2—Appearance of colon in case 5, showing a similar appearance of the cecum, ascending portion and the terminal ileum, also small areas of filling defect in the transverse colon and sigmoid.

region and some shooting pains in the anal area, as of hemorrhoids. September 30, a rectal tube was passed for a high enema. This apparently traumatized the rectum. From this time on, the symptoms had become intensified. The stools were loose and contained blood and mucus. Although he experienced abdominal and rectal discomfort, had some fever from time to time and did not feel well at times, he continued on his scheduled trip, visiting California and the Pacific Northwest. He was on his way home to Philadelphia when he sought medical advice in St. Paul.

On admission, physical examination was essentially negative except for tenderness in the left lower quadrant to deep palpation. There was also a palpable mass—probably a distended cecum—in the right lower quadrant.

Proctoscopic examination revealed a small ulcer with a soft elevated edge in the rectosigmoid junction, which was apparently due to the trauma caused by the self-introduced rectal tube, two weeks before. Biopsy from the ulcer revealed an acute inflammatory lesion. Because of the vague palpable mass in the right lower quadrant, a roentgen examination of the colon was done. There was a diffuse irregular filling defect with induration of the wall, as though by an infiltrating growth, with a narrowing of the lumen and an apparent shortening or shrinking involving the cecum and ascending colon, without evident spasticity, fluoroscopically. This was interpreted to be a diffuse, chronic, nontuberculous inflammatory lesion or possibly an infiltrating tumor (fig 1).

The patient was discharged on the same day. He was requested to bring in a specimen of feces, in view of the roentgen examination of the colon. This he did on the following day. The stool was soft, partly liquid and contained much mucus and some gross blood. Microscopically, sluggishly motile amebas in large numbers and a few cysts characteristic of *Endamoeba histolytica* were found. The following morning a sample of fresh stool was obtained which revealed many actively motile endamebas morphologically characteristic of the

histolytica type. Bacteriologic examination of the feces was negative for the organisms of the typhoid and dysentery groups. The Widal and other agglutination reactions were negative.

The patient was hospitalized, October 18. His temperature rose to 100 F on the second day. Urinalysis was negative. The blood showed hemoglobin, 71, erythrocytes, 4,110,000, leukocytes, 6,200 with 69 per cent neutrophils. A course of emetine injections was given and the patient was discharged, October 30, considerably improved. The boggy mass in the right lower quadrant gradually disappeared. The stools showed a few cysts from time to time but otherwise became normal in consistency and appearance.

While the patient himself was, at first, strongly of the opinion that the condition was due to water and foods at Yellowstone National Park, the fact that he spent eight days in Chicago before he proceeded toward the west pointed strongly to that city as a probable source of infection. While in Chicago, he stopped at Hotel C but ate most of his meals at Restaurant H on M Avenue. He ate one breakfast and a dinner at the hotel and a sandwich at the fair. The incubation period in this case is estimated to be from seven to fifteen days.

This case is of particular interest because of the rectal ulcer, which prompted a biopsy, and of the peculiar infiltrating type of a lesion in the cecum and ascending colon, which doubtless was due to the amebic infection. We were not prepared to make a diagnosis of amebic colitis from the roentgenograms, although in the light of our subsequent experience we believe that the roentgen finding of this disease is fairly typical and may be of aid in diagnosis.

CASE 2 (Dr A. R. Hall)—T. A. P., a man, aged 52, an insurance executive, was admitted to the hospital, October 19, complaining of diarrhea, tenderness and gas in the intestine, with a temperature of 101. The onset came with sore throat, soreness and stiffness of the neck, general malaise and weakness about a week before admission. The patient believed that he had not been feeling well since about the middle of July, when, while in his summer cottage, he had a first attack of

Fig 3—Low power view of the lesion in the rectum obtained by biopsy showing a deep mucosal creta with submucosal space filled with mucus exudate containing only a few scattered inflammatory cells.

diarrhea and "stomach symptoms" in light form. During a visit to Chicago, September 16-18, he suffered a terrific abdominal cramp with diarrhea which lasted two or three days. On admission there was a diffuse abdominal tenderness. The liver was enlarged and palpable. He was nauseated and vomited several times. He appeared acutely ill. The leukocyte count was 22,000 and the temperature rose to 103. The first stool

was semihliquid and contained mucus, some gross blood and pus. There were many motile amebas morphologically characteristic of *Endamoeba histolytica*.

The patient had a stormy course for a few days with the temperature remaining up around 103°. Roentgenologically, the liver was definitely enlarged but the diaphragm was not fixed. The temperature came down to the normal on the fifth day.

Fig. 4—High power view taken from the same section as figure 3 of an area in the mucous mass in the submucosa showing nests of amebic bodies and few inflammatory cells. Note apparent division of ameba.

after the institution of the emetine therapy. The stools became normal in consistency and appearance within a few days. The amebas disappeared on the third day. The liver decreased in size gradually to normal, with improvement. The patient was discharged after two weeks of hospitalization.

The patient had been a frequent visitor in Chicago since March, 1933. In all he visited eight times between March 23 and October 18, staying at various hotels, including Hotels P, E, M and C. He stopped at Hotel C, September 16-18, with his family. His meals were eaten at these hotels usually but also at the fair and at several restaurants, including Restaurant H. The patient traced his present trouble definitely back to his first attack in July, which was mild compared with the attack in September while a guest at Hotel C. The probable source of infection in this case is difficult to determine, since he had the first attack presumably in July. Whether the earlier attacks may have been due to dietary indiscretion is a justifiable conjecture, since the patient had a gastro-enterostomy for a duodenal ulcer in 1925, followed by a gastric resection because of a gastrojejunal ulcer the following year. If this proves correct, the source may be traced to Hotel C, in which event the incubation period for this case may be estimated to be between twenty-four and twenty-six days.

The case is of interest when considered in connection with case 6, the patient being one of his daughters. The case is of further interest since the clinical symptoms were so intense in the beginning as to arouse in the mind of the clinician a doubt as to whether this was a simple uncomplicated case of acute amebic dysentery. The cultural studies of the stools were negative.

CASE 3 (Dr. E. T. Herrmann)—P. B., a man aged 45, an attorney, was admitted to the hospital November 2 complaining of general pain and discomfort in the abdomen with explosive movements and diarrhea, mucus and blood in the stools. There was a rise in temperature. The abdomen was distended and tender over the lower portion. The liver and spleen were

not palpable. The present complaints began a day before admission. The first sample of feces contained much mucus and gross blood and showed many actively motile amebas, morphologically considered *Endamoeba histolytica*. On admission, the temperature was 102°, the leukocyte count 22,500. The temperature was normal on the fourth day and the leukocyte count 9,400 a week after admission.

Under the specific therapy, he has been progressing satisfactorily. No amebas or cysts have been found since his stools returned to normal on the fourth day.

The patient was in Chicago September 14-16, remaining at Club C. He returned there on the following week, September 21-22, and stayed at Hotel S. He took most of his meals at the club and the hotel but ate once at Restaurant H and once on the fair grounds. He remembered eating a sandwich with a glass of beer at Hotel C. The incubation period is estimated to be between fifteen and seventeen days.

CASE 4 (Dr. E. T. F. Richards)—M. O., a woman aged 41, a housewife, was admitted to the hospital, November 7, complaining of severe abdominal cramps and marked diarrhea. The present illness began about October 20, when she had cramps in the abdomen and bearing down and pulling pains with much gas in the intestine and frequent movements but no diarrhea at first. There was a general discomfort and malaise and a rise in temperature. About a week after the onset she developed a marked diarrhea which continued and became very severe. She lost her desire or taste for food. The stools were liquid, expelled explosively and contained blood and mucus grossly. *Endamoeba histolytica* was found in large numbers. There were seven and nine stools in the first two days following her admission. The patient was acutely ill and appeared very toxic. The temperature was from 100.6 to 102.4, with a pulse rate of from 120 to 144 per minute during

Fig. 5—Appearance of colon in case 7 portraying more advanced changes in the cecum, ascending colon and involvement of the transverse portion. The ileocecal valve is widely patent.

the first few days. The leukocyte count on admission was 19,450 with 88 per cent polymorphonuclears. The temperature came down to normal on the eighth day after the institution of the specific therapy. Her improvement was slow at first but she is now well on the way to recovery. The stools have been normal since the fifth day and no amebas or cysts have been found since the third day.

The patient visited Chicago, September 24, and remained until the 27th. She stopped at Hotel C and ate her meals there mostly. She visited the city two months before. No data are obtainable regarding this visit. The incubation period is calculated to be between twenty-three and twenty-six days.

It was noted that her stools, unlike those from other patients, were watery, mixed with streaks of thin mucus and dark brownish red. The mucus was not thick, glairy and semitransparent as in the typical case. Microscopically there were many pus cells and macrophages as well as fresh red blood cells. While no dysentery bacilli were isolated and the Widal test was negative, it is assumed that there was a mixed bacterial infection to cause this type of stools, which might also account for her extreme toxic state.

CASE 5 (Dr H. E. Hullsiek).—H. J. C., a man, aged 51, an industrial director, was first admitted to the hospital October 13, for the purpose of proctoscopic examination and biopsy.

Fig. 6.—Sigmoid from a case of systemic amebiasis showing a small infected diverticulum—the only primary lesion in the colon.

He first noticed abdominal cramps, gas, tenderness and diarrhea, August, 15. He complained of a poor appetite and had a general feeling of malaise. Though not acutely ill, he was feeling "rotten" and suffered from a vague abdominal distress most of the time with occasional recurrence of cramps and diarrhea. He had much tenesmus and a frequent desire to evacuate, without results. He consulted a physician, September 10, and underwent a general physical examination and a roentgen examination of the colon. These examinations were essentially negative except for a fissure of the anus, for which he was given suppositories. A month later, October 10, he consulted the present physician, who on proctoscopic examination found an area of peculiar diffuse induration involving the wall of the rectum, quite suggestive of a malignant growth, and a marked fibrous stricture of the anus. On admission two small pieces were removed through the proctoscope for rapid diagnosis. A frozen section of the specimen merely showed a chronic inflammation of the rectal mucosa. The surgeon was not satisfied with the diagnosis and arranged for a second biopsy later and discharged the patient. He returned

to his work, but the abdominal cramps were so severe that morphine was often required to relieve the pain. For several days following the biopsy, he had watery diarrhea as many as fourteen times in one day. (The history was obtained later.)

The patient was readmitted eighteen days later, October 31, for a second proctoscopic examination and biopsy. This again proved negative for a malignant growth. Eight days later, and only a few hours before he was to be discharged, a stool specimen was submitted for examination. It was soft, partly formed and partly liquid and contained much free mucus and gross blood. *Endamoeba histolytica* was at once demonstrated in large numbers and actively motile. His discharge was canceled and he was immediately put on the specific therapy.

The patient had no elevation of temperature and there was no increase in leukocytes, and apparently he was not acutely ill while in the hospital. He steadily improved and was discharged, November 16, after a course of treatment. The stools became mushy and bulky but were never free of cysts and occasionally showed sluggishly motile amebas in small numbers up to the day of discharge. A roentgen study of the colon at this time revealed changes in the cecum and ascending colon not unlike those found in other cases. The transverse colon and the rectosigmoid area also showed small, irregular filling defects due probably to superficial ulceration as well as to local spasm (fig. 2).

The patient visited most of the larger cities of the East and Middle West during the past year. He was in Chicago three times, from June 19 to June 23, September 15 and 16 and October 3 and 4. Since his abdominal symptoms began in the middle of August, the infection probably occurred during his first visit, which makes the incubation period from fifty-three to fifty-seven days. He stayed at Hotel A during all these visits, except one night at Hotel E. He ate his meals at the hotel as a rule but also ate at various restaurants, including Hotel C, Club I and Restaurant T, but never at the fair.

Serial sections of the second biopsy tissue from the rectal mucosa revealed an early typical amebic lesion, filled with a nonpurulent mucous exudate containing nests of amebic bodies. This was recognized following a discovery of *Endamoeba histolytica* in the stools (figs. 3 and 4).

CASE 6 (Dr W. R. Shannon).—R. P., a girl, aged 10 years, student, a daughter of patient 2, was admitted to the hospital, November 13, following a telephone conversation between her mother and the school nurse, who reported that the child was crying, with severe abdominal cramps. The mother at the time was with her husband, patient 2, who came up to the laboratory for examination of the stool. The mother was advised of the possibility of her daughter's condition being due to amebic dysentery and requested to submit the stools for examination. The parents brought the child to the hospital directly from the school and the stool was examined at once. The stool was copious in amount, soft, mushy and partly liquid. It contained much mucus but no gross blood. Microscopically there were many vegetative and precystic forms and a few cystic typical of *Endamoeba histolytica*. The child showed a distended abdomen with much gas and complained of pain and distress diffusely over the lower portion, causing her to double up. The temperature was normal. The leukocyte count was 15,400, with 87 per cent polymorphonuclears.

The child had a terrific reaction to a first dose of one eighth grain (0.008 Gm.) of emetine hydrochloride subcutaneously, but has since tolerated a regular course of injections and is now on her way to recovery. The stools became soft and mushy and at times formed and no longer show either the vegetative or the encysted form of *Endamoeba histolytica*.

The child with the rest of the family visited the fair at Chicago, stopping at Hotel C from September 16 to September 18. Most of the meals were taken at the

fair, but all the breakfasts and one or two other meals were eaten at the hotel

The question as to when and how this child became infected is of interest. If her father, patient 2, had already been infected when the family registered at Hotel C, September 16, it would be practically impossible to determine the origin of her infection, since there is every possibility of her father transmitting the disease to her. On the other hand, if her father had not become infected until his stop at Hotel C, it would be easy to trace the origin of her infection to the same hotel. Transmission of this disease from one member of the family to another is easily conceivable. Assuming that her infection was contracted at Hotel C, the incubation period is estimated to be from fifty-six to fifty-eight days.

CASE 7 (Dr J E Holt)—M M F, a woman aged 53, a housewife, was admitted to the hospital November 21 complaining of vague abdominal distress with diarrhea, which had been present, more or less during the past four months. July 18 while staying at Hotel P in Chicago the patient was seized with severe pain in the abdomen. She was seen by the hotel physician, who treated her symptomatically. There was much gas in the bowels but little diarrhea. She had a slight rise in temperature and some anorexia. She returned home, July 22. Her condition had not improved. Three days after her return, she consulted a physician. She had a temperature of 102° F. A diagnosis of "colitis" was made and she was admitted to a local hospital in the first part of August. Her complaints remained the same. She had spells of diarrhea, gas in the bowels and abdominal pains and distress. The temperature ranged from 99 to 101°. The stools were examined and reported negative for amebas as were the various agglutination tests on the blood. She was given a course of treatment, including medicated enemas. Since discharge from the hospital, her condition had remained essentially the same.

When admitted to this hospital, she was quite weak and complained of abdominal distress. The temperature was 101° and the leukocyte count 9000. A specimen of feces was obtained two days after admission. It was semiliquid and mixed with mucus but showed no gross blood. After a long search, two or three actively motile amebas, morphologically characteristic of *Endamoeba histolytica* were found. None of them, however, showed any ingested red blood cells. In view of the history which elicited her earlier visit to Chicago from July 4 to July 9, when she was registered at Hotel C, and of the subsequent course of her illness, it was felt justifiable to make a tentative diagnosis of amebic dysentery in order to institute a proper measure of therapy. The roentgenograms of the colon, too, revealed a characteristic deformity of the cecum and ascending colon which had been demonstrated in other cases of this series (fig 5). Three days later the leukocyte count was 6250 with 64 per cent neutrophils, including 14 per cent band forms.

The patient visited Chicago, July 4, and stopped at Hotel C until July 9. She ate at the hotel and at the fair and at various restaurants including Restaurant H. Her subsequent visit to Chicago occurred on July 15. She stopped at Hotel P and became ill while there. This gives an incubation period from nine to fourteen days.

Emphasis may be made of the extreme difficulty in examining the stools for *Endamoeba histolytica* from patients chronically ill with this disease in whom other therapy, including local treatment has already been given. A long and painstaking search is imperative. Yet there is every likelihood of missing the diagnosis.

CASE 8 (Dr J A Gehlen)—F B, a woman aged 30, housewife was referred to the laboratory for examination of the stools. She was not particularly ill at this time but had noticed an increase in the number of stools from once to four or five times a day. The stools were loose as a rule but never

at any time diarrheal. They contained a small amount of mucus and gross blood at each passage. This was first noted November 3. She noticed acute abdominal cramps, in mild form, previous to movements once or twice, shortly after the onset. The specimen was represented by a few well formed, hard, small masses coated partly with a thick glairy mucus and gross blood and several chunks of thick, clear, gelatinous mucus streaked with fresh blood. *Endamoeba histolytica* was present in typical form and large numbers, actively motile and ingesting red blood cells.

The patient was in Chicago, stopping at Hotel A from October 1 to October 5. She ate most of her meals at Hotel C. Her present symptoms began, November 3. The incubation period was therefore between twenty-nine and thirty-three days.

This patient represents the majority of ameba-infested individuals, in whom the symptoms are so negligible that under ordinary circumstances no medical advice may be sought by the victim.

CASE 9 (Dr Max Hoffman)—E H, a woman, aged 38, housewife was admitted to the hospital November 30, because of a slight diarrhea of a week's standing. There was no appreciable abdominal distress and no rise in temperature. A few days before admission, her attention was called to a radio talk on amebic dysentery in Chicago and also to an instance in which death presumably occurred from this condition. The stools were semiliquid and contained much mucus and a small amount of gross blood. There were many dead, vacuolated amebas, few sluggishly motile and one or two containing fresh red cells. Amebic dysentery was tentatively diagnosed and saline catharsis was ordered to obtain specimens from the cecum and high up. Many actively motile amebas characteristic of *Endamoeba histolytica* were demonstrated in the subsequent specimens.

The patient was in Chicago from September 8 to September 11. She and her husband stayed at a private home while visiting the fair. They ate two breakfasts at the home, one at the M F Restaurant and the remaining meals at the fair. She had been perfectly well until the onset of the present illness, which occurred, November 24, while on a hunting trip in the Northern woods. She had moderate diarrhea. This she attributed to the strenuous walk and chilling incident to hunting. There were no abdominal cramps or distress. The incubation period was from seventy-four to seventy-seven days in this case.

This is the only case of the series in which the hotels in the loop district of Chicago are not involved as the source of infection, which may be traced to the concessions on the fair grounds, the private home or a downtown restaurant. This is an example of an early case in which the lesion was apparently limited to the cecum, in which typical motile amebas were demonstrable only in stools obtained by catharsis. The roentgen examination of the colon in this case revealed only a slight degree of spasticity at the cecum and along the sigmoid and no appreciable amount of induration, shortening or filling defect such as observed in other cases of this series, indicating apparently an early stage of the disease.

SUMMARY AND COMMENT

1. Case 1 was diagnosed and the source of infection fairly definitely traced to Chicago one month before the public announcement of the outbreak in that city by the Associated Press November 10. Within twenty days five cases of amebic dysentery were diagnosed, and within a space of forty-seven days a total of nine cases all traceable to Chicago were recognized through this laboratory, a unique experience for one hospital of an average capacity in this part of the United States.

2 Clinically, cases 1 and 5 are of unusual interest because of their presenting symptoms and of the manner in which they were treated and diagnosed. Amebic proctitis may be confused with an infiltrating type of a growth, while amebic colitis of the cecum and ascending portion of the colon may be mistaken for a tumor or inflammatory mass requiring surgical intervention.

3 Case 6 illustrates the fact that the onset of the disease may be of dramatic suddenness without any apparent prodromal signs. An acute surgical condition of the abdomen may easily be considered, especially in children.

4 Case 7 represents a large group of neglected and mistreated patients in which the diagnosis is missed and the condition treated as "colitis" without specific therapy. Cases such as this may furnish many a difficult and embarrassing moment to the pathologist on whom the final diagnosis must rest, probably because of the altered intestinal flora occasioned by local medication.

5 Cases 8 and 9 are examples from another large group, representing those innocent carriers who show no appreciable signs or symptoms of intestinal disorders and therefore ordinarily do not consult a physician. They constitute a dangerous group in which lies a continued danger to public health.

6 Cases 2, 3 and 4 illustrate a typical clinical picture of acute amebic dysentery in different degrees of severity. Case 2 may be properly considered as a recurrent acute type from the history and manner of onset. The patient was quite toxic and showed a definite enlargement of the liver. Patient 4 was extremely toxic and showed a fulminating clinical picture. Her stools suggested a mixed infection in the colon. Case 3 presented a typical case of less severe type in which the condition was recognized and the treatment instituted immediately.

7 The approximate incubation period varied from seven to fifteen days to from seventy-four to seventy-seven days. More interesting was the number of days between the probable day of onset and the day of diagnosis. This varied from one day and two days to 125 days. In cases 1, 5 and 7 the diagnosis was not made when first seen by the physician. It was three days in case 1, sixty days in case 5, and 119 days in case 7 after the first visit to the physician that the diagnosis was definitely established. In cases 5 and 7, the original physician was no longer in attendance when the diagnosis was made. In cases 1, 2, 5 and 6 the discovery of *Endamoeba histolytica* by the laboratory was a distinct surprise to the attending physician, in others the condition was more or less suspected clinically, owing probably to the wide discussion of the cases already discovered in the hospital (and not due to the newspaper publicity). Patient 9 sought medical advice through a radio talk.

8 The physical appearance of the first stool was more or less characteristic, mucus and gross blood were prominently visible in six instances. In case 6 it was mushy and bulky and contained much mucus but no gross blood. In case 7 it was semiliquid and mixed with mucus but showed no gross blood. The variation in the character of the stools may be accounted for by the chronicity of the infection and the type of local treatment, which may change the physical and chemical nature of the fecal flora.

9 Laboratory diagnosis in each instance was made on the first specimen of stool with little difficulty. In case 7 it was necessary to make a prolonged search before the few organisms were partly identified. They might well have been missed under ordinary circumstances. The cysts of *Endamoeba histolytica* were found in three cases, in the first stool in cases 1 and 6, and after the institution of treatment in case 5. The disappearance in every case of motile amebas is sudden and dramatic within the first few days after emetine treatment is begun.

10 The origin of this infection, traced to Chicago, may not be confined to one or two hotels and restaurants, as generally believed. It is probable that a few other hotels and eating establishments and perhaps some central meat, vegetable and fruit supply houses may also be involved. It is not probable that eating concessions at the fair were a source, since all fair employees were given an examination before they were hired.

11 Another interesting feature of this series is the observation that nearly all the victims are the members of the higher social circle, whose hygienic habits are of the best.

12 During this period of six weeks, we have examined a large number of stools from twelve or more patients who had diarrhea of from a mild to severe degree with negative results. In at least one or two of them we may have missed the amebas or their cysts. Two members of the family of patient 3 showed the stools infested with *Endamoeba coli*.

SYMPTOMATOLOGY

The individual resistance and the character of the intestinal flora probably play an important part in the duration of the incubation period and the manner of onset in amebic infection in man. The incubation period in man is variously estimated at from five to 100 days. The usual prodromal signs of infection may often be so insignificant as to escape notice or may be entirely absent. The onset may be sudden, as in acute "surgical abdomen," for which operative measures have been considered. It may be insidious and indefinite. The presenting symptoms usually consist of abdominal discomfort in the form of severe cramps or gaseous distention and general soreness or a localized tenderness over the cecal area with or without diarrhea or frequent desire to evacuate. Diarrhea with the passage of mucus and blood, may be the most prominent initial feature, or it may be secondary or absent. Pains and tenesmus in the rectum may often be troublesome. The symptoms may soon disappear and be forgotten. One or several recurrences of the symptoms, often in more severe form may induce the patient to seek medical advice. There are doubtless many who consider the incident as an instance of "indigestion" or temporary bowel trouble attributable to dietary indiscretion and who fail to consult the physician. A few of the acute cases may develop severe, toxic symptoms with a high fever and an increased leukocyte count and a high percentage of young neutrophils ("band" form). Practically all cases, regardless of the degree of severity of the symptoms, readily respond to the specific therapy, as is shown by the rapid clinical improvement and disappearance of gross blood and amebas from the stools, as shown in the accompanying table.

LABORATORY DIAGNOSIS

The identification of *Endamoeba histolytica* is not always as simple as is generally believed. The character

of the stools in amebic dysentery may vary considerably. They may be liquid, soft and mushy or formed. Liquid, semiliquid or soft stools are the rule. A single amount is usually small. The most prominent feature is the conspicuous presence of mucus and gross, fresh blood. Often a sample of stool may be represented entirely by a small quantity of mucus and blood. The mucus is thick, glairy, transparent and usually unmixed with pus. It is not dull and membranous as in mucous colitis. The presence of pus usually indicates secondary infection or other coexisting acute inflammation and is not a cardinal feature.

Endamoeba histolytica is searched for in a small drop of the mucus mixed thoroughly in warm saline solu-

tion for demonstration in the majority of cases. The amebas ingesting fresh red blood cells are practically always demonstrated in acute cases, but in chronic or mistreated cases it may be practically impossible to find them. On standing, the amebas may undergo changes which may allow the formation of vacuoles or, occasionally, the invasion of bacteria and may cause the nucleus to appear more distinctly. All these possibilities must be borne in mind, since the specimens of feces submitted are not always typical or as desired, nor are the typical specimens obtainable.

While, therefore, I follow the teaching of the authorities that the finding of red blood cells within the vegetative form of amebas and the demonstration of

tion first under the lower power objective. The following criteria are considered essential in the identification of *Endamoeba histolytica* under the high power lens: 1. The motility is active and progressive, extremely so under favorable conditions. 2. The pseudopodia are clear, transparent, tongue-like or finger-like and often well demarcated from the endoplasm. 3. The endoplasm (cytoplasm) is finely granular, ground glass like and when fresh contains no bacteria, food particles, vacuoles, and the like and usually shows no clear outline of the nucleus. 4. The amebas ingest fresh red blood cells. 5. The typical four nucleated cysts should be demonstrated. The cysts are not observed as a rule during the acute stage and therefore the diagnosis may have to be made without

the four nucleated cysts should constitute the final diagnostic criteria of *Endamoeba histolytica*, I feel that, in experienced hands, a positive diagnosis, without either of the two, may be justified, at least in the face of an outbreak such as has been witnessed. Thus, when the lesion is confined in the cecum alone as is often the case during an early stage of the disease, the amebas may undergo changes during the passage through the remaining colon and not be found alive on reaching the rectum. One with experience may recognize them and order immediate catharsis to confirm the diagnosis.

In the absence of diarrhea or of gross blood and mucus the stools should be examined particularly for the encysted form. A saline purgative should then be

given to obtain a liquid passage. No final negative report should be given until at least three samples have been carefully examined.

A danger of a false positive report by the inexperienced is increasingly evident, especially in a sudden outbreak such as this, when technicians and clinical pathologists of limited experience on medical protozoology are called on to examine the stools from suspected individuals. Their negative report may be equally dangerous. It is evident that those who engage in the practice of laboratory medicine must be fully prepared to meet the situation, in the future. The present outbreak has afforded some of us the opportunity of further study on this particular type of intestinal protozoa.

An attempt to cultivate the amebas on artificial mediums has not been as successful as anticipated. The best that could be accomplished was the apparent prolongation of the life and active motility of the amebas for a period of forty-eight hours, Locke-egg-serum medium and liver infusion agar medium being used. Transplants were only partially successful.

A possibility of the routine use of the complement fixation test in amebiasis strongly suggests itself at this time. Such an attempt should be made in these as well as in other cases. The experimental work has already been successfully carried out by Craig,³ Sherwood,⁴ and others and has introduced a promising field in laboratory diagnosis of this disease.

According to Craig,⁵ Dobell claims that a single examination of the stools should develop about one third of the actual infection, while three examinations should show between one half and two thirds of the actual number of cases. Lynch⁶ emphasizes that "only a few are considered competent to identify anything but the cyst." Definite identification of *Endamoeba histolytica*, therefore, is not only a difficult task but, at times, a time-consuming procedure which should be fully appreciated by the medical profession.

ROENTGEN OBSERVATIONS

Roentgen study of the colon was carried out in six of these cases. In four, cases 1, 6, 7 and 9, the roentgenograms were made before the specific therapy was started, and in two, cases 2 and 5, they were taken after a course of treatment had been completed. In case 5 a previous roentgen examination of the colon had been made elsewhere, two months before the diagnosis of amebic dysentery was made but several weeks after the onset of the illness. There are, therefore, the roentgenograms in five cases, 1, 5, 6, 7 and 9, before treatment and in cases 2 and 5 after the first course of treatment. Patient 6 is a child and was examined on the day of onset, and the roentgenogram failed to show any particular changes on the films except possibly a slight spasm of the descending colon. In case 2, a treated case, and case 9, an early case, the observations were doubtful but suggestive in the light of those in the roentgenograms of the remaining cases, 1, 5 and 7.

The roentgen observations in amebic dysentery confirm the presence of the characteristic pathologic lesions, which are confined at first to the cecum, ascending colon and rectum. Not only the mere presence of the lesion but the character of the lesion is portrayed, particularly as it affects the proximal segment of the colon.

In none of the cases is spasm a prominent feature, in fact, very little spasticity is noted during fluoroscopy. No appreciable abnormality is noted until the barium mixture reaches the proximal portion of the colon, which fills readily and shows no suggestion of spasm during the period of fluoroscopic observation. The cecum appears elevated and the lumen diffusely narrowed and contracted and its outline irregular. There is no usual soft flexibility on manipulation but, on the contrary, a distinct induration and resistance. The ileocecal valve is widely patent, allowing the mixture to flow freely into the terminal ileum. The terminal ileum, too, presents an appearance somewhat similar to that of the adjoining portion of the colon. The appearance of the colon, fluoroscopically as well as roentgenographically, is easily interpreted as being due to a diffuse, irregular infiltration or induration similar in character to chronic hyperplastic tuberculosis or possibly diffuse infiltration of a tumor such as leukemia or Hodgkin's disease. In the absence of active spasm, tuberculosis may be ruled out but not definitely. Our diagnosis in case 1 rested between a chronic nontuberculous inflammation and an infiltrating growth, involving the cecum and ascending colon. In the light of the subsequent development, it is now easy to interpret the manifestations as being due to amebic colitis. The filling defects are caused by multiple, deep irregular ulcers with an overhanging edge and a diffuse edema and exudation involving all the layers of the wall but particularly the submucosa. The narrowing of the lumen is doubtless caused by a great inflammatory thickening of the wall. The shortening of the cecum is probably due to the semipermanent, spastic contraction in the presence of diffuse inflammation and fibrosis. This also results in the induration of the ileocecal ring, which causes a constant backflow of the colonic contents and consequent involvement of the terminal ileum. A somewhat similar appearance is obtained in the transverse colon of patient 7, who had been ill with "colitis" for many weeks before the diagnosis was finally established. This merely indicates the extension of the process into this portion of the colon. The roentgenograms in case 2, obtained after the patient had been discharged, reveal little of the changes here described. This may be explained by the fact that too much repair had already taken place in the wall of the colon to show the changes that may be present during the active stage of the disease.

The roentgenograms in these cases represent a picture depicting a well established pathologic lesion in the cecum and the ascending colon. Roentgenograms in an earlier stage of the disease, if obtainable, may show active spasticity and less pronounced deformity, filling defect and induration, as are suggested by the observations in cases 6 and 9. In case 5, in which the presence of motile amebas in small numbers was noted at the time of discharge from the hospital, when the roentgenograms were made, small irregular defects along the transverse portion as well as along the sigmoid and the rectum were observed, indicating the presence of active pathologic changes in these areas.

It should be emphasized that these roentgen observations are not specific for this disease but are merely an exact silhouette of the well established pathologic processes in the colon, occasioned by the invasion of *Endamoeba histolytica*, and may be of aid in determining the extent of involvement and in the differential diagnosis

PATHOLOGY

No death occurred in this series of nine cases. No material was therefore available for histopathologic study, for which the standard textbooks on pathology and a large number of publications on this disease are available. A monograph on amebic dysentery by Councilman and Lafleur¹ is considered a classic on the pathology of amebiasis.

Fortunately, a small piece of tissue from the rectum in case 5 furnishes an example of a characteristic initial lesion of this infection and may be described in detail.

It illustrates clearly the mode of invasion of these protozoa through the mucosa, which shows a slit or creta-like ulcer. This communicates with a large space in the submucosa caused by the cytolytic action of the invaders and filled with thick masses of mucus, containing only a few monocytes, neutrophils and eosinophils. One is impressed with a marked secretory activity of the epithelial cells and the type of exudate, which is nonpurulent and largely consists of mucus-like material. This may be considered an early, uncomplicated lesion due to the invasion of *Endamoeba histolytica*. A diligent search, in the serial sections, reveals a nest of amebas in the thick mucous secretion, which is adherent to the deep layer of the mucosa, constituting the inner lining of the space. With the advance of the process, coupled with the secondary infection that is bound to take place, this lesion will undoubtedly develop into a deep, irregular, undermining ulcer with an overhanging edge (figs 3 and 4).

Amebic lesions elsewhere in the body as a complication of intestinal amebiasis are not uncommon in the tropics though extremely rare in the Northern climate. Amebic liver abscess is occasionally encountered in Minnesota as a complication of a chronic amebic infection. I encountered in May, 1933 a case of amebic liver abscess rupturing into the pleural cavity, with metastatic pulmonary and cerebral abscesses and terminal embolic abscesses in the spleen and the wall of the small intestine in which the only demonstrable primary amebic lesion in the colon was represented by a small infected diverticulum located in the sigmoid (fig 6), though the stools contained, at times *Endamoeba histolytica* in large numbers and actively motile. This case is an example of a chronic amebic carrier who had never experienced any intestinal disorders but succumbed to a widespread systemic complication.

CONCLUSIONS

1. Nine cases of amebic dysentery were recognized within a period of forty-seven days in a general hospital of an average size in a Northern city of 250,000 population, in the United States. This is a unique experience. Infection in all nine cases was definitely traced to Chicago which demonstrates probably a widespread dissemination of this disease throughout the country as a direct result of the Chicago epidemic.
2. The presenting symptoms show a wide variation, depending on the character of the attack and on the stage of the disease.

3. The initial symptoms, when elicited, are not always identical. There are atypical cases in which the first symptoms may be misleading or so insignificant and commonplace that no medical relief is considered necessary by the patient.

4. There is danger of a false positive report in the laboratory diagnosis of this disease by the inexperienced. Careful and painstaking search for the organism should be undertaken in suspected and neglected cases.

5. Roentgen examination may be of value as an aid in differential diagnosis.

6. Amebas were demonstrated in a section of a piece of tissue from the rectum, in a case suggesting a malignant growth. The histologic appearance of the lesion presents the characteristic initial changes due to the invasion of *Endamoeba histolytica*.

DOUBLE PULLEY TRACTION IN
FRACTURES OF THE SHAFT
OF THE HUMERUS

REPORT OF CASE

LESTER BLUM, MD

NEW YORK

It has been the custom in the surgical service of the Beekman Street Hospital to treat the majority of fractures of the shaft of the humerus with skin traction, using the Blake board, the forearm being suspended at right angles to the arm. This method, while it has produced good functional results, has definite disadvantages. The anatomic result is often only fair and may occasionally be termed poor. It is not feasible in compound fractures. There is a constant tendency for the adhesive to slip, and in some cases the irritation of the skin constitutes a real problem. When the patient is an unusually muscular individual or the fracture is compounded, pin traction through the olecranon or the lower end of the humerus is employed. This is an operative procedure of some technical nicety, of use only in adults, and the end-result may be no better than with the use of skin traction.

Some years ago, Russell¹ introduced his well known method of traction for use in the treatment of fractures of the femur. He described certain technical specifications at which he had arrived on an empirical basis that, on mathematical analysis, have been shown to subserve the main purpose of attaining more accurate axis traction. By observing these principles I have been able successfully to adapt a similar type of traction for use in humerus fractures.

The apparatus (fig 1) consists of a broad, well padded cuff which partially encircles the elbow, with its pressure broadly distributed over the skin of the cubital fossa. There is a continuous length of rope leading from the cuff around single pulley A through part of double pulley B, to pulley C which is incorporated in the hand spreader, and back to the other part of double pulley B to suspend the weight. The spreader is attached to the forearm by moleskin strips. The entire system is carried by a right angle frame, which is so constructed as to allow movement of pulleys A and B without releasing the traction. The frame is attached to the Gatch portion of the bed so that the

¹ Councilman, W. T. and Lafleur, H. A. Amebic Dysentery. J. R. H. Inc. Ill. Ch. 2. 1931.

From the surgical service of the Beekman Street Hospital.
¹ Russell, P. H. Fracture of the Femur. A Clinical Study. Phila. J. Surg. 11: 491-502 (Jan.) 1924.

entire apparatus moves as the patient is raised up in bed without the essential angles being altered. The arm rests on a soft pillow and is held at 90 degrees abduction from the body. This side of the bed is raised on shock blocks about 3 inches. A Balkan frame is used merely to offer greater security to the traction frame and to help the patient adjust himself in bed. It is not a necessary part of the apparatus.

Fig 1—The patient as he actually appeared in the double pulley traction apparatus. He is shown with the head of the bed elevated to about 45 degrees. The lowest pulley is marked *A*, the one farthest from the patient is double pulley *B*, and the pulley on the hand spreader is marked *C*. The felt protecting the skin of the cubital fossa is completely hidden by the cuff. The shock blocks elevating this side of the bed are not visible.

We believe that there are definite advantages in the treatment of fractures of the shaft of the humerus with this system. It offers an easily adjustable method of attaining mathematically accurate axis traction (fig 2). There are two directions of pull, as shown in figure 2. One is somewhat downward (*OA*), transmitted through the cubital cuff, and is equal in force to the suspended weight. The other (*OB*) is upward, transmitted through the hand spreader, and is equal in pull to twice the suspended weight, since it is a double pulley system. The resultant (*OC'*) of these forces, lies one third of the distance nearer the greater force (*OB*). By simple adjustment of the pulleys on the frame, these angles can be so arranged in any given case as to throw the resultant in accurate alignment with the proximal fragment. The arrangement can be made by gross estimate and can be accurately checked by measuring the angles on the roentgen film with a protractor. The resultant pull is usually equal to a little more than twice the suspended weight.

In the second place, the entire arm is free. This is of importance in compound fractures and is of readily apparent value in the administration of physical therapy. In other types of traction, any attempt at elevating the head of the bed inevitably results in some alteration of the line of traction, with the false point motion at the site of fracture. In this system the essential angles are not altered by raising the patient in bed. This has been checked by the fluoroscope. The advantage of being so able to elevate the head of the bed, especially in elderly patients, is quite obvious.

REPORT OF CASE

N A, a Negro youth, aged 13, admitted to the Beckman Street Hospital, May 7, 1933, had just injured his right arm in the subway. Clinical and fluoroscopic examinations of the arm, to which emergency traction had been applied, revealed an oblique fracture at the junction of the middle and lower thirds of the shaft of the humerus. There was about half an inch overriding and definite anterior angulation. He was immediately put up in double pulley traction with 3 pounds weight. After seven hours, it was noted that the anterior angulation was still clinically obvious, and so a half pound was added. A roentgenogram after twenty-four hours revealed excellent alignment with no angulation nor overriding. By measuring the angles with the protractor and calculating the resultant, we discovered that we had empirically attained what was mathematically the correct line of pull. The weight was reduced to 3 pounds to avoid overpull and the roentgen check-up, twenty-four hours later, showed no change. The patient during this time was perfectly comfortable, the only sedatives used being phenobarbital and codeine, which were given for the first three nights. There was no complaint of antecubital pressure, or of tingling or numbness of the finger and the patient was raised up for meals and lowered to the supine position in the evening. He was able to pronate and supinate his forearm. On the fifth day, a sling balanced by a weight was substituted for the pillow as support for the arm. A check-up film, after twenty-four hours, revealed that the addition had so disturbed the equilibrium of forces by its anterior pull as to result in an anterior angulation with a deviation of 22 degrees of the lower fragment. To remedy this the original pillow was restored, the sling was discarded and the angles of the apparatus were adjusted, without a change being made in the weight, so that the resultant was again in alignment with the proximal fragment. We were successful in correcting the position so that on the lateral roentgen view there was only 10 degrees anterior bowing, and on the anteroposterior view the alignment was almost exact. A roentgenogram on the seventeenth day revealed the presence of callus, which was even more evident on the twenty-sixth day.

On the thirty-seventh day, it was felt that the patient could with safety be removed from the apparatus. This was done, and he was allowed up with the extremity in a sling, and bass

Fig 2—*OC* represents the line of the shaft of the humerus. *OA* is the line of force pulling through the cubital cuff; its length is equal to three units (or pounds). *OB* is the line of force pulling through the hand spreader; its length is equal to six units (or pounds). *OC'* represents the resultant pull both in direction and in force; it can be arithmetically calculated or can be worked out trigonometrically as here shown by taking it as the diagonal of the parallelogram of forces.

wood coaptation splints to the arm. There was no evidence of any impairment of function of the elbow joint. Active motion was immediately instituted.

COMMENT

I believe that this is a simple, easily applied type of traction, which involves neither operative procedure nor anesthesia and offers certain definite advantages in the treatment of fractures of the shaft of the humerus.

TRACING THE TRANSMISSION OF SYPHILIS

DUDLEY C SMITH, M.D.

AND

WILLIAM A BRUMFIELD, Jr, M.D.
CHARLOTTESVILLE, VA

There is an attitude of aloofness shown by physicians in all branches of medicine toward the prevention of syphilis. This is due partly to the absence of proper example and leadership by the syphilologists, syphilis clinics and epidemiologists. Sexual transmission with its moral aspects has seemed to be an insurmountable hazard but is actually only a mental handicap. In fact, this type of close contact makes a source of infection easier to determine.

The average physician and specialist does not often look beyond the syphilitic patient. He shies away from seeming to seek patients and becoming embroiled in domestic affairs. Some of this attitude is due to false professional ethics and part is due to lack of energy and patience. The problem is such an enormous one

Chart 1—Group in which all follow up measures were used

when tackled in a wholesale way that most epidemiologists have not had the daring to assail it.

All of the facts necessary for an effective epidemiologic attack against syphilis are known, at least to the point of practical application. Several lines of approach to the problem are frequently mentioned. These are education (lay and professional), medical prophylaxis, isolation of infectious cases, modern treatment, determination of sources of infections and follow-up of contacts. Prophylaxis, treatment and isolation have received the greatest attention in parts of Europe, and it is estimated that the incidence of syphilis has decreased 50 per cent. Education, particularly as related to sex hygiene and morality, has had the major role in the United States and apparently it has been of little value in preventing the spread of the disease. The horrible ocre of immorality has caused the living aside of valuable prevention tools. The American epidemiologists and syphilologists have joined hands with the societies for the suppression of vice instead of

setting to work against this communicable disease. It is true that the public, syphilitic persons and others, has traditional feelings about this malady and its relation to vice. The medical man should consider this as a fact but should not be forced off the main track by it. Thought has been centered too much on removing the sin rather than reducing the penalty.

The determination of the sources of infection and the follow-up of contacts have not received either abroad or in this country the emphasis they merit. These phases, analogous to the carrier problems of other communicable diseases, have all but been completely ignored both in practice and in the literature. Sources of infection may be easily determined since only a few persons would be suspected. Elaborate investigation is unnecessary. The patient in the office or clinic may be depended on to give the desired information.

It has been assumed that the follow-up of contacts and the follow-back to the origin of the contagion is idealistic but impracticable, because patients will not divulge the names of sexual partners. It can be stated emphatically that such is not the case. This method of approach has been carried out as a routine measure for the past several years in the University of Virginia Hospital and Clinic, and the results are quite requiring. In some instances the patients are unable to name their consorts, but in only two occasions have we had patients deliberately refuse to name them. In one of these episodes a second patient was the means of clearing up the focus.

This investigation requires a considerable amount of patience and tact. The subject is approached slowly, every effort being made to gain the confidence of the patient. The nature of the disease is explained in detail. After the various phases of the disease relating to the patient himself are discussed, the facts of the infection in regard to others are enumerated. When it is felt that the person's cooperation is attained, maneuvers toward securing possible sources of infection and contacts since infection are made. If the first attempt is unsuccessful, other attempts may break the barrier. Usually several efforts at different visits are necessary before all the relevant information

is obtained. The names and addresses of all contacts and consorts are determined. These are not recorded in writing in the presence of the patient.

The contact without a complaint who comes in for consultation offers a slightly different type of problem. It is explained why he was advised to come for examination. Emphasis is placed on this attempt to look after his safety and the welfare of others. The importance of syphilis as a disease

is stressed. He is also questioned about other contacts. He is asked for the names of other persons who have been associated with any of his consorts. When the patient or contact hesitates to reveal names, he is urged to advise personally those who he knows or thinks might have been exposed to seek medical advice. A number of patients and exposed contacts are thus developed into effective sanitary officers.

Occasionally a contact or patient denies sex episodes at first, but when confronted with the fact that another patient has already named him or her, they begin to talk. As an example, a girl with condylomata lata, who flatly denied sexual relations at first when interviewed tactfully, admitted one exposure. She was told that some one else had named her as a contact. Before she left the clinic she had revealed the names of seven sexual companions and had not named the person already known. In another instance, a young married woman with secondary lesions denied extramarital exposures in the beginning. During the interview she named six extramarital contacts and revealed the names of four women associated with her in clandestine prostitution.

The follow-up of contacts and tracing sources of infection in order to be most effective should be started immediately. Infectious patients should be started on sterilizing therapy as quickly as possible so as to reduce the period of contagiousness and all suspects gotten under observation to make it possible to begin treatment at the first diagnostic evidence of infection. The patient is instructed to try to get his or her contacts to be examined and advised. Letters are sent to the contacts requesting them to report for examination. A nurse may visit the contacts and urge them to see the physician. When all other measures fail, the suspects are reported to the health officer.

To have contacts come for examination through the advice of their friends or associates is ideal. Each new patient informs his friends in turn until all contacts are brought under observation. A small group which was cleared up entirely in this way is shown in chart 3.

Chart 3—Illustrative group showing contacts of a syphilitic patient

he also may have acquired it. No mention of syphilis is made, although it is written on the stationery of the department. If no response is had, a second letter is mailed strongly advising examination. Copies of all letters are put with the suspect's hospital chart, if he has one, and then if he should report to the hospital for any purpose he will be properly referred. Occasionally the patient is unable to give the addresses of contacts and a few letters are returned unclaimed, but on the whole the results have been very satisfactory.

An intelligent nurse can persuade contacts to report when other methods have been unsuccessful. The aid of the health department is solicited only as a last resort. Persuasion is better than enforcement procedures.

Indexed punch-cards were made in our clinic and private practice covering a period of about twenty months and from these the following data were tabu-

Chart 4—Illustrative group showing contacts of a syphilitic patient

lated. Exclusive of family surveys in heredosyphilis, cases in which sources of infection were not known or could not be reached and late or tertiary cases, there were 119 patients questioned. There were 242 names of contacts given. There were 196 individual names, exclusive of duplicates. There were 93 cases of syphilis discovered and treated by us. The number of persons stimulated to seek examination and treatment elsewhere is not known.

Tables 1 to 5 summarize promiscuity rate, contact rate, infection rate, stage of infection of source cases and results of case investigations.

Chart 1 shows a group in which all follow-up measures were used. Nineteen (thirteen men and six women) in this group of twenty-five persons were investigated in the clinic. All of these were found to be infected. Seven had secondary lesions at the time of admission. Nine men had primary lesions at their first visit. The diagnosis was made in three women by positive serologic tests. All of the men and five of the women were handled by letters or messages and the visiting nurse. The aid of the health department was necessary in one instance. Undoubtedly some of these persons would have eventually obtained proper medical attention had a follow-up study not been attempted, but they were brought under treatment earlier than would have been the case otherwise. The period of infectiousness was shortened and the possibility of cure increased. The diagnosis was made at the earliest possible moment in those persons seen dur-

SUMMARY

It is practical to trace sources of infection and exposures in syphilis. By these measures a larger proportion of cases are brought under observation the period of infectiousness reduced and the secondarily infected ratio thereby decreased.

ABSTRACT OF DISCUSSION

DR THOMAS PARRAN, JR., Albany, N. Y. The authors have presented a new method in the control of syphilis, which to my mind is as important as the discovery of a new drug. It is up to the medical profession of this country to decide whether or not it will avail itself of this new weapon. The work of Drs. Smith and Brumfield is quite conclusive in showing that it is practical both in white and in Negro patients to trace the source of infection and to bring the sources under treatment. A physician would not consider treating a case of smallpox without investigating fully the source of infection. He would either undertake this himself or report to the health department and expect the health department to make the investigation. On the other hand, one does not feel any such responsibility in cases of early syphilis. Yet the tracing of the source of syphilis is no more difficult than tracing the source of smallpox and is just as important. As a matter of fact, it is much easier, for the person knows more definitely the source from which he may have acquired the disease. Two years ago, Dr. Munson of my staff described seventeen epidemics of syphilis that had been traced to their source. About 100 patients were located in this series of outbreaks and most of them were brought under treatment. He has since reported an additional series of syphilis epidemics. It requires patience, ingenuity and tact, but the difficulties are not insurmountable. It is up to physicians to do one of two things—either accept this as their own responsibility or report to the health department in order that it may undertake the job. We have excellent cooperation from the medical profession in New York State in our program of venereal disease control. We have found that it is practical to use not only medical officers but trained public health nurses to make these epidemiologic investigations. Dr. Smith and his associates are to be congratulated on their work. They have shown clearly that they can get 50 per cent of these cases under treatment. I am convinced that syphilis is kept alive by a series of local epidemics, which can be traced and controlled. The authors say that syphilis is on the increase. My own investigations lead me to the same conclusion. In New York State we have found that there were 3000 more cases under treatment in 1930 than in 1927. Similar studies by the U. S. Public Health Service show an increase also.

DR DUDLEY C. SMITH, University, Va. All of the 119 cases shown on the chart were in the first year of the disease. This shows that most syphilis is transmitted in the early stages. It is, of course, well known that in the later years of the disease there may be mucocutaneous relapses, which serve as sources of infection although it is not of major epidemiologic importance. It is true, as Dr. Parran states, that new cases of syphilis occur in series of more or less segregated epidemics. It should be emphasized that in this entire group the aid of the public health department was not required except in one instance. The physician is undoubtedly best equipped to handle the sociological and diplomatic phase of syphilis. Tactful persuasion after acquiring the patient's confidence prepares the ground for the epidemiologic survey as well as laying the foundation so that the patient will continue to follow directions through a minimal standard of treatment. All types of patients—intelligent, ignorant, careless, neurotic, honest and criminal—can be led a long way by a skillful and persuasive physician.

HYPERINSULINISM, A DEFINITE DISEASE ENTITY

ETIOLOGY, PATHOLOGY, SYMPTOMS, DIAGNOSIS, PROGNOSIS AND TREATMENT OF SPONTANEOUS INSULOGENIC HYPOLYCEMIA (HYPERINSULINISM)

SEALE HARRIS, M.D.

BIRMINGHAM, ALA

Hyperinsulinism, also called the "hunger" disease because hunger, associated with weakness, nervousness and other manifestations of hypoglycemia is the most constant symptom has been known to exist for ten years¹. At least a hundred cases have been reported by American and European clinicians, surgeons and pathologists who have made thorough studies of all phases of hypoglycemia due to the hypersecretion of the islet cells of the pancreas. Sufficient data have accumulated in medical literature to warrant the discussion of hyperinsulinism as a definite disease entity. In this paper the effort will be made to outline the etiology, pathology, symptoms, diagnosis and treatment of hyperinsulinism as derived from published reports of many cases and from ten years' study of the disease.

DEFINITION

Hyperinsulinism, the antithesis of diabetes mellitus (hypoinsulinism), may be defined as a disease of the pancreas resulting from the spontaneous excessive secretion of insulin by the islands of Langerhans and characterized clinically by hypoglycemia with its concomitant symptoms, i.e., hunger, weakness, nervousness, tremors, sweating, trembling and mental lapses. Unconsciousness and convulsions may occur in the severe cases.

Dysinsulinism is a condition, or disease, associated with the uncontrolled secretion of the islet cells of the pancreas resulting in hyperglycemia alternating with or followed by hypoglycemia, and characterized clinically by symptoms of hypo-insulinism (diabetes mellitus), and at times by the syndrome of hyperinsulinism.

Hypo-insulinism (diabetes mellitus) is essentially a disease of the pancreas resulting from the deficient secretion of insulin by the islands of Langerhans and is characterized clinically by hyperglycemia, polyuria, polyphagia, polydipsia, emaciation and weakness. Gangrene of the lower extremities, carbuncles and acidosis with and without coma, may occur in the neglected cases of hypo-insulinism.

FREQUENCY

No doubt hyperinsulinism has existed as long as has diabetes and was not recognized, just as hyperthyroidism, now known to be a frequent disease, for a long time was considered a nervous disorder and was not recognized as a disease of the thyroid. Physicians now practicing medicine can remember when the first cases of appendicitis were recognized and operations performed, and it may be predicted that in the near future hyperinsulinism will become recognized as a compara-

tively frequent disease which in most cases is amenable to treatment, either by dieting or by surgery.

A chronological review² of the cases of hyperinsulinism reported in the United States and Canada up to 1931 indicates that hyperinsulinism not only is a frequent condition but that it may cause a wide range of symptoms which heretofore have been diagnosed as being due to other causes but which in reality are manifestations of insulogenic hypoglycemia. Marsh³ in 1930 reported nine cases of hyperinsulinism, which occurred in his private practice. Jean Sigwald⁴ and Rather, report a number of cases of hyperinsulinism ("hypoglycémie par hyper-pancréatique"). Sigwald also reviews a number of reported European cases and presents a large series of experiments on animals in which he describes the manifestations of hypoglycemia induced by varying doses of insulin. Sippe and Bostock, in Sidney, Australia, in a review of the general subject of hypoglycemia, report twenty-five cases as having occurred in their private practice and in the Brisbane General Hospital. In discussing the frequency of chronic hypoglycemia they say "In a large series of cases met with in general medical practice, the percentage of cases of hypoglycemia was 0.47 and that of diabetes 0.51. Thus it will be seen that hypoglycemia is practically as common as hyperglycemia."

Cambridge in 1930 reported 200 cases of "chronic hypoglycemia." He is of the opinion that the condition is of hepatogenous origin, though he considers that the pancreas may be a contributing factor in producing the hypoglycemia.

Judging from the number of cases of hyperinsulinism now being reported by many clinicians and from blood sugar studies in 3,076 cases, in my series of 6,641 adult patients largely ambulatory with gastro-intestinal and nutritional disorders, it seems probable that hyperinsulinism is almost as frequent as the opposite secretory disorder of the insulin-forming cells of the pancreas, hypo-insulinism (diabetes mellitus). Of the recorded fasting blood sugars on 3,076 patients, 535 were diabetic. Of the remaining 2,541 nondiabetic patients, 242 had hyperglycemia, i.e., fasting blood sugars above 0.120 per cent. No doubt many of these were cases of true diabetes, but most of the patients were under observation for only two or three days and the opportunity was not given for further study in their cases. Of the 2,541 nondiabetic cases, 218 showed hypoglycemia of varying degrees. Of these, 86 showed unmistakable symptoms of hyperinsulinism and dextrose tolerance tests or repeated fasting blood sugars confirmed the diagnosis. Fifty-eight of the cases of hypoglycemia presented symptoms of hyperinsulinism but were considered borderline cases, while seventy-four patients found to have hypoglycemia in the routine fasting blood sugar examinations had no symptoms of hyperinsulinism. It is probable that some of the latter two groups, if thoroughly studied, would prove to be hyperinsulinism.

Careful history taking, fasting blood sugars, dextrose tolerance tests, and blood sugar studies at the time of many heretofore unexplained nervous attacks, and in periods of unconsciousness with and without convulsions will prove that many of them are due to hyper-

Owing to lack of space this article is abbreviated in THE JOURNAL. The complete article appears in the author's reprints.

insulinism. The physician with laboratory facilities who keeps up with medical literature will find many cases of hyperinsulinism in his regular practice.

Since a number of cases of epilepsy and epileptiform attacks have been found to be associated with hyperinsulinism, every patient having petit mal and grand mal attacks should have thorough blood sugar studies made before he is stigmatized with the diagnosis of epilepsy. It is believed that many cases now diagnosed as idiopathic epilepsy soon will be classified as belonging to the severe type of hyperinsulinism, in which recurring attacks of unconsciousness and convulsions are symptoms.

ETIOLOGY

Since hyperinsulinism and diabetes (hypo-insulinism) are secretory disorders of the pancreas, it seems probable that the same causes may produce the two, and of these a previous, usually unrecognized, pancreatitis is perhaps the most important factor. The fact that several patients have been observed who have diabetes and hyperinsulinism (dysinsulinism) indicates that the two have a common origin. In one of my cases of subacute pancreatitis there was disturbed carbohydrate metabolism with symptoms of hyperinsulinism.

Probably the most important underlying or predisposing cause of the pancreatitis that precedes hyperinsulinism and diabetes is a diet deficient in vitamins. About twenty years ago, McCollum, Simmonds⁶ and Parsons expressed the opinion that the role of food in the etiology of many diseases "involves increased susceptibility to infection, due to lowered resistance caused by faulty diet." McCarrison's⁷ classic experiments seem to have proved that foods of low vitamin content predispose to all abdominal infections. Other nutritionists, Barnett Sure⁸ in particular, stress the role of diets deficient in vitamins A and B in the etiology of abdominal infections. The anatomic and circulatory relations of the pancreas would seem to make it particularly vulnerable to secondary involvement from gallbladder, intestinal and other abdominal infections.⁹ If it is accepted as a fact that faulty diets predispose to the infections that play a part in the etiology of pancreatitis, sugar-saturated, vitamin-starved Americans, i.e., those who live largely on white flour bread, white potatoes, white rice, lean meats, sugar saturated coffee, and sugar-laden desserts, with candy and soft drinks between meals, would seem to be prone to become victims of pancreatic disorders, including hyperinsulinism and diabetes.¹⁰ With a damaged pancreas as a factor, and since the ingestion of carbohydrates stimulates insulinogenesis,¹¹ it seems probable that the excessive use of sugars and starches in the American diet may play another important part as an exciting cause in the incidence of hyperinsulinism.

Focal infections from the mouth, tonsils, colon, rectum, prostate and the uterus and its adnexa may be the primary causes of the pancreatitis that precedes hyperinsulinism. Likewise the general infections such as typhoid, influenza and the diseases of childhood

particularly mumps, may involve the pancreas as a complication, and the pancreatitis may be unrecognized.

In one of my cases of epilepsy associated with hyperinsulinism the first attack occurred about four weeks after an abdominal injury from which the patient was in bed three weeks suffering from abdominal pain and tenderness, nausea and vomiting, symptoms that suggest injury to the pancreas. It therefore seems that trauma may be a factor in the etiology of hyperinsulinism.

Three diabetic patients with hyperglycemia have given clear histories of previous hypoglycemic symptoms, indicating that the first manifestation of dysfunction of the pancreas was hyperinsulinism, and diabetes was a sequence. One of these patients, with a history of hyperinsulinism before she became obese and developed diabetes, has a son who has typical symptoms of mild hyperinsulinism.¹² This suggests that the familial tendency exists in hyperinsulinism as in diabetes (hypo-insulinism). Sippe and Bostock express the opinion that "the hypoglycemic entity possesses a definite hereditary tendency."

Worry and other emotional disturbances, and overwork—particularly prolonged physical exertion, thus exhausting the suprarenals, which seem to act conjointly with the islet cells of the pancreas—may play a part in producing excessive and uncontrolled insulinogenesis.

A number of the severe cases of hyperinsulinism have been proved to be due to adenomas of the pancreas (insulomas). In other cases, carcinoma of the islands of Langerhans has been found at operation or at necropsy. It seems probable that neoplasms of the pancreas may be as important factors in the etiology of hyperinsulinism as adenomas and other tumors of the thyroid are in the pathogenesis of hyperthyroidism.

PATHOLOGY

In several cases of hyperinsulinism in which operation has been done, normal appearing pancreases have been found. Histologic studies have not revealed any pathologic changes in those cases. It therefore seems that, as in diabetes, hyperinsulinism may occur without any demonstrable lesion of the pancreas.

Hyperplastic islet cells were found by Phillips¹³ at necropsy on a Negro who died in a hypoglycemic attack. Phillips cited the case of Dubreuil and Anderodias¹⁴ of giant islands of Langerhans in a child born of a diabetic mother. Phillips also cited a case reported by Gray and Feemster¹⁵ of "compensatory hypertrophy and hyperplasia of the islands of Langerhans in the pancreas of a child born of a diabetic mother." The blood sugar of the child on the day it died was 0.067 per cent. It seems probable that at least in the severe cases of hyperinsulinism that have existed for some time there may be hyperplasia of the islet cells, though as in other glandular organs the insulinogenic cells may function excessively without any evident change in the cell structure.

The first pathologically proved case of hyperinsulinism was reported by Wilder, Allan and Robertson.¹⁶ A

physician, aged 40, had recurring attacks of unconsciousness and convulsions (blood sugar, 0.030 per cent). Exploratory laparotomy revealed an inoperable carcinoma of the pancreas. The patient died a month later. Necropsy showed a carcinoma of the islands of Langerhans with metastatic nodules in the liver, which showed a distinct resemblance to the islet cells of the pancreas. An extract from the metastatic nodules in the liver injected into rabbits showed insulin activity. The report of this case presents one of the most thorough studies of hyperinsulinism that is recorded in medical literature.

Neoplasms of the islet cells of the pancreas associated with hyperinsulinism have also been studied and reported by Thalheimer and Murphy,¹⁷ McClenahan and Norris,¹⁸ Warren,¹⁹ Howland and Campbell and their associates,²⁰ Graham and Womack,²¹ Smith and Seibel,²² and Bast, Schmidt and Sevringhaus.²³ Smith and Seibel's study of five adenomas found by operations and by autopsy on hypoglycemic patients probably present the most comprehensive report that has been made on the pathology of adenomas found associated with hyperinsulinism.

SYMPTOMS

The Mild Type—In the mild cases of hyperinsulinism the patient complains most frequently of excessive hunger, weakness, nervousness, anxiety or irritability, one or two hours before meals. All these subjective symptoms are relieved by eating, only to recur three or four hours after meals and often during the night. In addition, there may be trembling, flushed face, or pallor, particularly around the lips, profuse perspiration and tachycardia. These symptoms may be exaggerated by exercise, overwork, either mental or physical, worry and other emotional disturbances. Recurring headaches and inability to concentrate the mind on work late in the afternoon have been observed. Fatigability and insomnia are frequent complaints. Vertigo, dyspnea, "smothering spells," cardiac palpitation and precordial

Chart 1 (case 1)—Hyperinsulinism. Complaint hunger and weak spells. A blood sugar curve May 25 1931 eight years after the diagnosis of hyperinsulinism had been made. B average normal blood sugar curve. The blood sugar levels (hypoglycemia) were almost constant during ten years' observation. In the charts the sugar is given in milligrams per hundred cubic centimeters of blood.

pain have been noted and have been relieved by dieting, with frequent feedings between meals.

CASE 1—H J R, a man, aged 52, a mechanic who was 5 feet 10½ inches (180 cm) tall and weighed 139 pounds (63 Kg) minimum, 186 pounds (84.4 Kg) maximum, was

seen, Oct 5, 1923, with the following symptoms: extreme hunger, weakness, nervousness, trembling and profuse perspiration just before the noon and evening meals and at night. The "hunger spells" were relieved by eating. The symptoms were controlled by a low carbohydrate diet and frequent feedings. With lapses in diet the "hunger spells" come on, which are relieved by eating.

In the mild cases the fasting blood sugar usually ranges between 0.075 and 0.060 per cent, and the dextrose tolerance curve is of the low flat type that even in one hour does not go higher than 0.110 per cent and in two or three hours has fallen to 0.060 per cent and in some cases lower. Normal fasting blood sugars have been noted at times with patients who have hypoglycemic symptoms, but at other times the level in the same patients is abnormally low. Therefore, repeated

Chart 2 (case 2)—Moderately severe hyperinsulinism following unregulated reduction regimen, psychasthenia or actual psychosis. A low flat blood sugar levels, particularly one and two hours after 100 Gm. of dextrose was given. B average normal blood sugar level.

fasting blood sugar tests should be made before the diagnosis of hyperinsulinism is made or is abandoned. In some cases, not all, the patient's hypoglycemic symptoms are reproduced when his blood sugar falls to its lowest level after a dextrose tolerance test.

Mild cases of hyperinsulinism have also been reported by Gibson and Larimer,²⁴ John,²⁵ Liu Shih-Hao and Chang Hsiao-Chien,²⁶ Pribram,²⁷ Hovie and Lisherness,²⁸ Winans,²⁹ Waters,³⁰ Sexton,³¹ Marsh,³ Sippe and Bostock,⁶ and others. The authors mentioned, in their published reports of their cases, have described many of the symptoms outlined as occurring in the mild types of hyperinsulinism.

Moderately Severe Type—In the moderately severe cases of hyperinsulinism the symptoms outlined as occurring in the mild type may be present in an exaggerated form. The hunger, weakness, nervousness, trembling and sweating are more pronounced, and eating gives relief for only one or two hours when more food is demanded in order that the victim can continue to perform his regular duties. This type appears more frequently in women who complain that they are so weak before breakfast that they cannot do anything. They feel better after breakfast for an hour or two and then become so weak that they have to go to bed, or they learn that they can eat and in a few minutes feel strong enough to go back to work. The vicious circle of getting hungry and weak and eating keeps up until the victim becomes obese. Many of the moder-

ately severe cases reported have shown overweight, the effort to reduce has exaggerated the symptoms of hyperinsulinism to such an extent that some of the patients had attacks of what has been diagnosed as hysteria of the grave type, and some have been thought to be psychotic

CASE 2—Mrs A E W, aged 43, 5 feet 2 inches (157.5 cm) tall, had reduced from 210 to 133 pounds (from 95 to 60 Kg) in the past year. About two or three hours after meals and during the night she had spells of weakness, nervousness, mental lapses and irritability and was unable to do her housework. She was mentally depressed and had ideas or delusions, of persecution. The question of sending her to a psychopathic hospital was considered. She would feel better and stronger after eating but had been dieting to reduce by not eating supper. Glycosuria was present at times. The patient was very much improved by a low carbohydrate, moderately high fat diet for three meals and orange juice or tomato juice every one or two hours between meals. Her mental and physical condition was much improved.

In some of the moderately severe cases there are brief mental lapses, resembling petit mal attacks. In fact, several cases have been reported in which petit mal attacks had been found associated with hyperinsulinism and in which the attacks were controlled by dieting. In the more severe cases there may be brief periods of actual unconsciousness, and transient hemiplegias may occur.

In the moderately severe type the fasting blood sugar level usually ranges from 0.060 to 0.050 per cent, though in some cases it may be above 0.060 per cent, or fall below 0.050 per cent. The symptoms may or may not be reproduced by a dextrose tolerance test when the blood sugar runs lower than 0.055 per cent.

Moderately severe cases of hyperinsulinism have been reported by many other clinicians whose published articles have described the symptoms mentioned in this article. Among the authors whose contributions have enriched the literature on the symptoms of hyperinsulinism may be mentioned Jonas,³² Sprunt,³³ Gammon and Tenery,³⁴ Heyn,³⁵ Cammidge,³⁶ Sendrail and Planques,³⁷ Stenstrom,³⁸ Rathery and Sigwald,³⁹ Escudero,⁴⁰ Ravid,⁴¹ Shepherdson⁴² and Krause,⁴³ and others, some of whose names have been listed, have reported mild cases.

The Severe Type—The severe cases of hyperinsulinism are manifested by attacks of unconsciousness, either with or without convulsions. In some cases there is associated violent delirium. In one of the cases reported by Wilder⁴⁴ the patient developed violent delirium, disturbances of sleep and somnambulism. He

had to be confined to a straight jacket because of repeated attacks of manic delirium which were provoked whenever his blood sugar level fell below normal." Wilder concludes by saying "It is probable that many of these cases are being dismissed with such diagnoses as hysteria, or epilepsy, or schizophrenia, and that more cases of hyperinsulinism will come to light when blood sugar determinations are made with greater frequency. The nervous manifestations of hyperthyroidism formerly led to this disease being included among the neuroses."

CASE 3—A H B, a man, aged 22, a college student, 5 feet 9½ inches (177 cm) tall, weighing 136 pounds (61.7 Kg), seen, April 25, 1933, had had almost daily attacks of physical and mental exhaustion since November, 1931, when he became very nervous—"frightened and shaky"—an hour or two before meals. He drank four cups of coffee and two glasses of coca cola a day for relief of and to prevent attacks. Frequently he would become so weak that he would have to lie down before his noon meal. He always felt fine after eating. The symptoms grew worse until October, 1932, when he became dizzy and then unconscious for about twenty minutes, there were no convulsions. He had five attacks of unconsciousness after that. The anxious, nervous, weak feelings between meals have continued.

The patient was hospitalized for two weeks on a diet of 60 Gm of carbohydrate, 60 Gm of protein and 150 Gm of fat, with food every one or two hours between meals and when he awoke at night. He has been free from symptoms except that slight weakness occurred one night about 11 o'clock,

Chart 3 (case 3)—Severe hyperinsulinism recurring attacks of unconsciousness. A, hyperinsulinism blood sugar curve; B, average normal blood sugar curve. When the blood sugar fell to 0.040 per cent the symptoms of the hunger attacks were reproduced, i. e., the patient became very weak and pale particularly around the lips. He was very nervous and trembled but obtained immediate relief from eating.

but he was relieved immediately by taking orange juice. He has learned to weigh and measure food and calculate his menus to carry out the diet at home. He returned for a check up May 29. He has had no symptoms except one time when he could not get orange juice or other food between meals. He then became weak and trembled but was relieved by eating. The fasting blood sugar was 0.066, compared with 0.05 per cent when the treatment was begun.

In many of the cases of the severe type a diagnosis of epilepsy had been made but abandoned when the attacks of convulsions were found to be associated with hypoglycemia, as in the cases of Neilson and Eggleston.⁴⁵ Several cases of what appeared to be true "idiopathic" epilepsy, in which the patients bit their tongues or received burns and other injuries while unconscious, were found to have been associated with hyperinsulinism.⁴⁶

Scrimgeour, Schmidt and Bast²³ reported a case of hyperinsulinism with hypoglycemia (blood sugar, 0.040 per cent) in which the patient was in status epilepticus. Removal of a tumor (carcinoma) of the tail of the pancreas relieved the hypoglycemic symptoms.

In a number of the severe cases of hyperinsulinism the patients have appeared as if they were intoxicated

from alcohol but would become normal after taking food. Some have complained of "crazy spells," and actual psychotic symptoms have been observed by several clinicians. In one of Graham's⁴⁷ cases the psychosis was relieved by the removal of two small adenomas which appeared to be the cause of the hyperinsulinism.

Abdominal pain has been pronounced in several reported cases. The pain of severe hyperinsulinism has simulated appendicitis, gallbladder infection and duodenal ulcer, so that exploratory operations, with removal of the appendix and gallbladder and gastroenterostomies, have been performed without relieving the abdominal pain. The pain of hyperinsulinism usually is exaggerated during the attacks, though it may be present more or less constantly. In some cases it is more marked one or two hours after meals. The pain usually is in the upper part of the abdomen, sometimes radiating to the left. Tenderness over the pancreas may be elicited on deep pressure in some cases. It is probable that pain and tenderness over the upper part of the abdomen in hyperinsulinism occurs most frequently in cases in which there are adenomas or other tumors of the pancreas, but in a narcoleptic patient in whom abdominal pain was a prominent symptom, no pathologic changes of the pancreas were found at operation, which relieved not only the hypoglycemia but also the pain.⁴⁶ This patient, in addition to the abdominal pain, had the typical Gelineau⁴⁸ syndrome of narcolepsy, i. e., attacks of unconsciousness associated with cataplexy.

In severe cases of hyperinsulinism there is usually a history of mild symptoms for several years before the attacks of unconsciousness and convulsions supervened. In other words, in the severe cases of hyperinsulinism the symptoms may progress from those ordinarily observed in the reaction following an overdose of insulin to the symptoms observed in the moderately severe cases and then into the unconscious or convulsive period. Usually there are mild symptoms and often petit mal attacks between the attacks of unconsciousness and convulsions in the severe type.

Some of the most severe cases of hyperinsulinism appear to be of the acute fulminating type in which the patient goes into hypoglycemic coma and remains unconscious for hours before death occurs. In other patients spontaneous recovery occurs after he has been unconscious for hours. In the severe cases of the epileptiform type, the patient may go for weeks or months without seizures and then have several grand mal attacks in a few hours. In most of the severe cases of hyperinsulinism reported there has been the tendency for the hypoglycemic attacks to become more frequent and progressively more serious unless relieved by dietary management or by surgery. As in the mild and moderately severe types of hyperinsulinism, in the severe cases the hypoglycemic attacks may be induced by mental or physical strain, worry, grief and other emotional disturbances.

The blood sugar levels in the severe type of hypoglycemia usually are very low, below 0.050 per cent. Readings of 0.040, 0.035 and 0.027 per cent have been found, in Weil's⁴⁹ case the blood sugar fell to zero.

Woodyatt⁵⁰ and Millard Smith⁵¹ have reported zero levels in hypoglycemia from overdoses of insulin, but both patients recovered after sugar administration. In two of Neilson and Eggleston's⁴⁶ cases of "epileptiform convulsions" the fasting blood sugar level was not very low, only 0.069 and 0.064 per cent. The dextrose tolerance test usually brings out much lower blood sugar levels than are found in the same patient when fasting blood sugars have been made. In several instances the convulsions and mental and nervous symptoms have been induced when the blood sugar fell very low from four to six hours after the 100 Gm of dextrose was given. In one of my epileptic patients, a woman who had grand mal attacks during menstruation, in a dextrose tolerance test between catamenial periods the lowest blood sugar level was 0.060 per cent. She became weak and had to go to bed but had no convulsions. In the dextrose tolerance test made during menstruation, when a seizure was expected the blood sugar level went to 0.050 per cent, at which time she had a typical epileptic convulsion.

The severe cases of hyperinsulinism that have been reported have attracted more attention than have the milder types, perhaps for the reason that the symptoms have been serious and usually clear cut, and the results of medical and surgical treatment have been dramatic. Pathologic studies from specimens removed by operation, or at autopsy, have been productive of proof that hyperinsulinism is a definite disease entity due in many cases to neoplasms. Among those who have made important contributions to the study of the severe type of hyperinsulinism, associated with attacks of unconsciousness, with or without convulsions, may be mentioned Wilder and his associates,¹⁰ Allan,¹¹ Thalhimer and Murphy,¹² the Finneys,⁵² Hartman,⁵⁴ Howland Campbell, Maltby and Robinson,²⁰ Neilson and Eggleston,⁴⁶ Carr, Parker, Grave, Fisher and Larrimore,⁵⁵ Schmidt and Carey,⁵⁶ Phillips,⁵¹ Weil,⁴⁹ McGavern,⁵⁷ Womack, Gnani and Graham,²¹ Sevringhaus, Schmidt and Bast,⁷³ Holman,⁵⁸ Guy-Larache, Lelourdy and Bussiere,⁵⁹ Stenstrom,³⁸ Pettersson,⁶⁰ Krause,⁴³ and Sippe and Bostock.

DYSINSULINISM

The uncontrolled secretion of insulin, excessive at times and resulting in hypoglycemia, which may alternate with or be followed by hypofunction of the islet cells with hyperglycemia, is manifested by inconstant symptoms of both hyperinsulinism and diabetes mellitus (hypo-insulinism). In some cases the hypoglycemic symptoms predominate and in others hyperglycemic phenomena are more pronounced. The symptoms of dysinsulinism may be mild and irregular, moderately

severe and bizarre, or so severe that attacks of unconsciousness and convulsions and hypoglycemic coma and death may occur in patients known to have diabetes.

Symptoms of dysinsulinism may be brought out in dieting diabetic patients, particularly in the mild overweight cases, but severe diabetes may coexist with severe hyperinsulinism. In such cases the hypoglycemic symptoms usually present the more serious problem.

My first case diagnosed as dysinsulinism was in January, 1924.¹⁰ An obese woman who a year before, when she weighed 210 pounds (95 Kg.) had had glycosuria, was sent to me as a diabetic patient. She had reduced, by dieting, to 160 pounds (72.6 Kg.), and complained of having "spells of weakness and nervousness" at about 1 or 2 o'clock in the morning. She had found from experience that eating would relieve the symptoms, so that she kept an orange or a glass of milk on the table by her bed. Her blood sugar during an attack was 0.047 per cent. She was relieved promptly by frequent feedings of a low carbohydrate diet, consisting largely of the 5 and 10 per cent vegetables and fruits, with sufficient proteins and fats. Since then I have had three other cases of dysinsulinism.

CASE 4—C. H. M., a man, aged 41, a laundry manager, 5 feet 5 inches (165 cm.) tall, weighing 127 pounds (57.6 Kg.), seen Nov. 16, 1930, complained of polyuria, glycosuria, and a nervous, weak feeling in the middle of the morning and afternoon, which was relieved by taking food. The fasting blood sugar was 0.060 per cent. Glycosuria was present constantly for two years, 4 Gm. being excreted in twenty-four hours. The hypoglycemic symptoms were relieved on a weighed and measured diet of 120 Gm. of carbohydrate, 60 Gm. of protein and 180 Gm. of fat, with food every two hours, but the glycosuria persists. The patient increased his weight 12 pounds (5.4 Kg.). The fasting blood sugar, Oct. 16, 1932, was 0.085 per cent.

In the last few years, several similar cases have been reported and the low blood sugars have been attributed to hypersecretion of insulin by Jonas,²² John,²³ Harrop,²² Neilson and Eggleston,⁴⁰ Howland and Campbell and their associates²⁰ and Weil.⁴⁹

DIAGNOSIS

A tentative diagnosis may be made from the symptoms, i. e., hunger, weakness, nervousness and the like (insulin reaction) in mild cases, and recurring attacks of mental lapses, convulsions, unconsciousness and coma in the severe cases. If the patient is relieved by reducing the carbohydrates and increasing the fats in his diet, with frequent feedings, the diagnosis of hyperinsulinism may be assumed. A positive diagnosis can be made only from repeated fasting blood sugar studies and carbohydrate tolerance tests showing hypoglycemia, i. e., blood sugar concentration below 70 mg. per hundred cubic centimeters and by excluding all other causes of hypoglycemia except the excessive secretion of insulin by the islet cells of the pancreas.

The patient receiving a dextrose tolerance test should be observed very carefully to determine his reaction to the low blood sugar levels in from three to five hours after the ingestion of the 100 Gm. of dextrose. In some such cases the symptoms of which the patient complains are reproduced. In one of the epileptic patients a typical grand mal seizure occurred while the patient was undergoing a dextrose tolerance test when the blood sugar level fell to 0.050 per cent. Lennox and Cobb¹ in two out of seven times produced grand

mal attacks in an epileptic patient by giving him insulin. In one of the seven times he was mentally confused but had no convulsion when the blood sugar level was 0.025 per cent. At other times the patient had epileptic attacks when his blood sugar was normal. Gammon and Tenery³⁴ reproduced the symptoms of hypoglycemia in their case of hyperinsulinism by giving the patient 10 units of insulin. It is hardly necessary to give insulin as a diagnostic procedure in hyperinsulinism because the blood sugar levels after a dextrose tolerance test usually are sufficiently low to give the patient mild hypoglycemic symptoms.

Every possible cause of hypoglycemia besides pancreatic disease should be considered including studies of all the other organs of internal secretion, excluding them as factors if possible before making the diagnosis of hyperinsulinism in an epileptic or narcoleptic patient.

Since hyperinsulinism has been manifested by symptoms of hysteria of a psychoneuroasthenia, neurocirculatory asthenia, psychoses, brain tumors, epilepsy, narcolepsy, status epilepticus, epileptiform convulsions, appendicitis, gallbladder infection, duodenal ulcer and other diseases, a differential diagnosis from those conditions can be made by blood sugar studies. Hyperinsulinism is invariably associated with hypoglycemia. It should be remembered however, that, in patients who have hypoglycemic symptoms, fasting blood sugars are not always low. Therefore, repeated and varied

Chart 4 (case 4)—Dysinsulinism mild diabetes and hypoglycemic symptoms. A low fasting blood sugar rising slowly above normal with slow drop to subnormal level. B average blood sugar curve.

blood sugar studies should be made before hypoglycemia is excluded in suspected cases of hyperinsulinism. It should be remembered also that the patient with hyperinsulinism may have other diseases that may or may not affect the hypoglycemic symptoms. Thus, two cases of hyperinsulinism in syphilitic patients have been observed in which antisyphilitic treatment did not affect the blood sugar levels or the symptoms of hypoglycemia.

Cases of marked degrees of hypoglycemia due to organic diseases or functional disturbances of other organs besides the pancreas, have been reported as having been due to (a) deficient glycogenesis in the liver, from poisons such as arsphenamine or other arsenicals, phenylhydrazine, phosphorus or other hepatotoxins (Cross and Blackford⁶⁴), and from massive tumor of the liver (Nadler and Wolfer⁶⁵); (b) inadequate mobilization of glycogen due to deficient secretion of the suprarenals as in the case reported by Anderson⁶⁶ in which the autopsy revealed an adenoma of the left suprarenal gland and in Addison's disease (Wadsworth⁶⁷); (c) pituitary dysfunction (Cushing⁶⁸, Josef

Wilder⁶⁹), (d) thyroid dysfunction, a possible factor in the etiology of hypoglycemic convulsions (Zubiran⁷⁰), and (e) ovarian dysfunction, as in the case of hyperinsulinism of Weil,⁴⁹ in which a woman with very low blood sugar levels constantly and frequently had the symptoms of an insulin reaction between her catamenial periods, but had convulsions only just before and during menstruation

PROGNOSIS

The prognosis of hyperinsulinism depends on the degree and character of the associated pancreatic lesion. It is good in the functional cases when an intelligent patient will carry out dietary instructions.

On account of the bulimia and the polyphagia that is pathognomonic of hyperinsulinism, obesity often results. Prolonged overfunction, with exhaustion, of the islet cells may be followed by hypo-insulinism (diabetes mellitus). Clinical evidences suggest that the patient with hyperinsulinism is a potential diabetic patient. I have had three diabetic patients with histories of unmistakable symptoms of hyperinsulinism before the symptoms of diabetes were observed. Therefore, early diagnosis and early dietary management may prevent the patient with mild or moderately severe hyperinsulinism from becoming diabetic, the clinician may thus aid in combating the increasing death rate from diabetes.⁷¹

Spontaneous recovery from the attacks of convulsions and unconsciousness due to hyperinsulinism usually takes place, but a number of deaths have been reported from hypoglycemic coma, in some of which unsuspected adenomas of the pancreas have been found at autopsy.

In the severe cases that cannot be controlled by dieting, the hope of cure is offered by surgery, i. e., partial resection of the pancreas, or removal of insulinoma. Early diagnosis is important in neoplasms of the pancreas, because delayed surgery may result in the condition becoming inoperable.

TREATMENT

The problem of dieting in hyperinsulinism is much the same as in diabetes mellitus (hypo-insulinism) in that each patient has to be dieted to suit his particular needs. It is necessary to arrange a diet that will nourish the patient properly, providing sufficient amounts of carbohydrates, proteins and fats, with due consideration to its vitamin content. As far as the quantity is concerned, it should have a lower carbohydrate content than in diabetes, with sufficient calories from fats to maintain normal body weight and physical vigor. The protein content depends on the age and weight of the individual from 60 to 75 Gm. for an adult weighing 70 Kg. (154 pounds).

The adult patient of average height and weight with hyperinsulinism should have about 2,250 calories, from 90 to 120 Gm. of carbohydrates, from 60 to 75 Gm. of proteins and the remainder in fats (cream and butter), divided into from five to seven feedings a day.

In the underweight, asthenic patient with hyperinsulinism, a high fat diet of 90 Gm. of carbohydrate, from 200 to 300 Gm. of fat, and from 60 to 75 Gm. of protein, divided into five or six feedings a day, will keep the blood sugar at a sufficiently high level to pre-

vent hypoglycemic symptoms and will build up the patient's general health and state of nutrition.

Careful blood sugar studies should be made on each patient for a few days after being placed on a diet for hyperinsulinism, during which time his food should be weighed and measured. It is just as necessary to teach the patient with hyperinsulinism food values and to calculate and arrange the menus suited to his particular case, as it is to teach "diabetic arithmetic" to patients with hypo-insulinism (diabetes mellitus).

Highland Avenue at Sacramento Street

ABSTRACT OF DISCUSSION

DR. RUSSELL M. WILDER, Rochester, Minn. This subject has interested me greatly since I had the opportunity, with Allan, Power and Robertson, to study the case of island carcinoma to which Dr. Harris has referred. The existence of a state of hyperinsulinism was definitely proved in that case by obtaining insulin-like extracts from the hepatic metastases of the tumor. The report of this observation has been followed by a number of other reports of similar cases. In some of these, island tumors have been found and the resection of them has resulted in the complete relief of the syndrome of hypoglycemia. In others, no tumors were discovered. Reviewing the subject recently (*Internal Clin.* 2:1 [June] 1933) I was able to cite sixteen cases presenting tumors of the islets of Langerhans. Fourteen had been associated with symptoms of hypoglycemia; nine were diagnosed clinically and treated surgically. Multiple tumors were present in a case reported by Franck, in one reported by Smith and Seibel, and in one of the cases at the Mayo Clinic. In five additional cases of hypoglycemia, hypertrophy of the islets had been noted, but such hypertrophy is frequently seen when there is no evidence of excessive insulin production. In seven other cases of hypoglycemia, two examined at autopsy and five at surgical operations, the pancreas appeared to be normal. Information is thus available concerning twenty-nine cases of this hypoglycemia syndrome in which the opportunity has been given to examine the pancreas. Tumors were noted in only fifteen of them. The clinical differentiation between cases with and those without tumor has been for us impossible. The severity of the symptoms has been great in both groups of cases. The dextrose tolerance test has not been helpful. Extreme degrees of variation in the height of the blood sugar curve and in the rapidity and degree of its descent have been seen in both groups of cases. Dr. Harris suggests that patients with hyperinsulinism may be potentially diabetic and that diabetes may follow a period of hyperinsulinism. We have seen the reverse of this in two cases—diabetes first and hypoglycemia later. I am not entirely prepared to accept the idea of a faulty pancreas in those cases of hypoglycemia which present no neoplasm. It is true that typical diabetes mellitus is not infrequently seen with no morphologic abnormality of the pancreas. By analogy, hyperfunction of the islets of Langerhans might be expected even in the absence of their anatomic alteration. However, hyperglycemia as contrasted to true diabetes mellitus, can be produced by a variety of disturbances without any evident involvement of the pancreas, and similarly hypoglycemia may be brought about by a variety of causes. Dr. Harris in 1923 happily suggested the possibility of the clinical state of hyperinsulinism, but the diagnosis of his early cases, those on which he based his suggestion, was substantiated only by the fact that the blood sugar was low and that food gave relief. There was no proof of an excess of insulin. Cammidge, observing similar cases about the same time, inferred with equal reasonableness that the liver was responsible. The organ chiefly concerned with the regulation of the blood sugar is the liver, and the secretion of the pancreas is only one of various factors that influence its ability to handle sugar. Recent observations indicate that similar quanta of insulin have different effects under differing conditions. I refer particularly to the extreme insulin sensitiveness of hypophysectomized animals (Barnes). Similar insulin sensitiveness has been produced experimentally by thyroidectomy, by denervation of the suprarenal capsules and by splanchne-

tomy (de Takats) Our knowledge, then, is still too fragmentary to accept the assumption of an excessive insulin production merely on the basis of hypoglycemia. Particularly is this true in the rather numerous cases presenting milder degrees of what Dr Harris calls hyperinsulinism. A pertinent discussion of this matter appears from the pen of the editor of the May issue of the *Annals of Internal Medicine*. The present evidence, as stated in this editorial, seems to indicate that tumor of the islets is among the rarest causes of hypoglycemia, and for the present it would seem more in accordance with our actual lack of knowledge to designate all cases of hypoglycemia in which no definite proof of cause exists as spontaneous or idiopathic hypoglycemia rather than as hyperinsulinism.

DR HENRY J JOHN, Cleveland While hypoglycemia with its classic symptomatology, is the outstanding manifestation of hyperinsulinism, many persons in perfect health have marked hypoglycemia and no symptoms. Hyperinsulinism is not merely hypoglycemia. I feel, as Dr Wilder does, that there is some other factor of importance. There are two types of hyperinsulinism, the exogenous and the endogenous. Years ago I published reports of two cases presenting the exogenous type of hyperinsulinism. Both patients had glycosuria and hyperthyroidism, but neither of them had diabetes. Their treatment at home had consisted of large doses of insulin, which had produced the classic hypoglycemic symptoms. In endogenous hyperinsulinism there is hyperfunction of the islets themselves or else an adenoma which either secretes too much insulin or stimulates the islets to secrete an excess of insulin. The treatment for hyperinsulinism has progressed through various phases. The first and most obvious method of relief was learned from the patients themselves. Even before the condition was known as an entity, the patients had learned that the ingestion of carbohydrates relieved them. When hyperinsulinism was definitely recognized as such, the problem presented was just the opposite of that encountered in diabetes and so frequent carbohydrate feedings and an extra feeding at bedtime were administered to these patients. It was not the ideal treatment, because the excessive carbohydrate was continually stimulating the pancreas to produce more and more insulin, the very condition that the treatment was supposed to combat. The next step was to modify the diet, giving the patient less carbohydrate and more fat in order to retard absorption of the carbohydrate and the resultant hyperglycemia and thus to eliminate the acute stimulation of insulin production and hypoglycemia. A third method of treatment was surgical removal of a portion of the pancreas, in order to reduce the number of secreting islets in an effort to decrease the excessive production of insulin. Another step in the treatment of hyperinsulinism is the administration of insulin, which I have tried recently with exceptionally good results in one case. The rationale for this method of treatment is briefly as follows. The ingestion of food produces hyperglycemia which in turn stimulates the insulogenic apparatus to insulin secretion, and this is followed by a drop in the level of blood sugar. In normal persons the intake of dextrose and the secretion of insulin are nicely balanced but in patients with diabetes or with hyperinsulinism there is some defect in the mechanism in one or the other direction.

DR GLA DE TAKATS Chicago During the past few years an attempt has been made to produce an increased secretion of insulin in the dog by producing a hypertrophy and hyperplasia of the islet tissue. This was found to be possible in the animal and to a certain extent also in the human juvenile diabetic patient. One may find however in the cases of hyperinsulinism not only an excessive insulin secretion but also an increased sensitivity to insulin. Tests for insulin susceptibility have not been determined frequently enough in patients with diabetes but on the basis of a few well observed cases it can be said that there is a wide variation in the individual with diabetes and also in the so-called normal individual as to susceptibility to insulin. It is quite possible then, that some of these patients with spontaneous hypoglycemia do not actually secrete an excessive amount of insulin but they become because of nervous or glandular mechanisms temporarily sensitive to insulin. Thus it is known that epinephrine insufficiency and pituitary insufficiency will produce a hypersensitivity to insulin. Spinal shock in diabetic patients also increases insulin sensitivity. From the surgical standpoint the attack on the

pancreas is not any more dangerous than any upper abdominal operation on the well controlled patient. I should like to emphasize, contrary to the usual opinion, that the danger of pancreatic necrosis is very slight. Pancreatic secretion is inactive in the pancreas and an aseptic operation will not activate the pancreatic ferments. As a matter of fact the cases reported in which the adenoma of the pancreas has been removed show that there was not one single instance of post-operative pancreatic necrosis.

DR SEALE HARRIS, Birmingham Ala I am sorry that I didn't have the time to discuss the diagnosis of hyperinsulinism in the fifteen minutes allowed for presenting a paper. In my paper I stress the fact that a positive diagnosis of hyperinsulinism can be made only from repeated fasting blood sugar studies and carbohydrate tolerance tests showing hypoglycemia, namely, a blood sugar concentration below 70, and by excluding all other causes of hypoglycemia except the excessive secretion of insulin by the islet cells of the pancreas. It is not possible at times to exclude all the other causes of hypoglycemia except hyperinsulinism, any more than can be done in making a diagnosis of diabetes from hyperglycemia and glycosuria. It seems likely that there are many mild cases of hyperinsulinism just as there are mild cases of diabetes, and I think that hyperinsulinism occurs perhaps as frequently as hypo-insulinism (diabetes mellitus), the opposite secretory disturbance of the islet cells of the pancreas. Hypoglycemia may be due to deficient glycogenesis. A number of cases of hypoglycemia have been reported as resulting from massive tumor of the liver. Inadequate mobilization of glycogen due to deficient secretion of the suprarenals is also a cause of hypoglycemia, as in the case reported by Anderson, in which there was marked hypoglycemia and the autopsy revealed an adenoma of the left suprarenal gland. Hypoglycemia may be due to thyroid dysfunction, and to hypophyseal dysfunction, as Cushing has pointed out. There are other causes of hypoglycemia. The important thing in making a diagnosis of hyperinsulinism is to study the cases carefully and to come to an accurate diagnosis from repeated blood sugar studies, excluding all other causes of hypoglycemia except the excessive secretion of insulin by the islet cells of the pancreas. One can guess pretty definitely in the mild cases of hyperinsulinism from such clinical symptoms as hunger, weakness, nervousness and distress three or four hours after eating which are relieved by taking food, that one is dealing with hypoglycemia and a very large proportion of such cases are due to an excessive secretion of insulin by the islet cells. Of course, one should not stop at symptoms but should study the cases carefully, making blood sugar studies and eliminating all other factors in hypoglycemia, except the excessive secretion of the islet cells of the pancreas, before a positive diagnosis of hyperinsulinism is made.

Coughs—I would particularly ask your attention to coughs.

There is the revolting hawking morning pharyngeal cough of chronic pharyngitis best manifest in the alcoholic. There are the annoying habit coughs of children which cause no harm excepting to the inexperienced mother the painful voiceless coughs of grave laryngeal disease the brassy cough of thoracic aneurysm and the phthisical cough which I find difficult to describe although it has quite definite features of its own. It is not so effortful but in late cases, as productive as the bronchitic cough, being less tenacious the sputum is more easily ejected the cough is moister and unattended by rillonchus in the very advanced case it may have a hollow whear quality. We have also the unmistakable paroxysm of whooping cough with its repeated expiratory efforts usually (but not always) culminating in the final inspiratory stridor. How often I have picked up my ears during a ward round and caught the eye of my house physician in relation to his latest unsuspected admission as bronchitis to one of the cots. I used the adjective unmistakable in connection with the cough of pertussis but it is worth remembering that a foreign body in the bronchus or a small undischarged pulmonary abscess may give rise to severe and prolonged paroxysms of coughing which are not very dissimilar—Rule J A. The Training and Use of the Senses in Clinical Work. *Gulf Hosp Gaz* 47 421 (Oct. 28) 1933

Clinical Notes, Suggestions and New Instruments

URTICARIA OF SEVENTEEN YEARS DURATION REPORT OF CASE TREATED SUCCESSFULLY

JOHN L. EMMETT, M.D. AND ARCH H. LOGAN, M.D. ROCHESTER, MINN.

Urticaria is often one of the most discouraging problems the physician is called on to treat. Although definitely associated with the great allergic triad hay fever, eczema and urticaria, it often defies all attempts to identify the sensitizing factor. Such diagnoses as physical allergy and allergy produced by products of metabolism are often resorted to. The case here presented is one that had defied all attempts to identify the exciting cause and had finally been considered a case of physical allergy with a large nervous element.

REPORT OF CASE

A white woman, aged 30, single, entered the Mayo Clinic, Aug. 29, 1932, complaining of a heat rash that had been present since puberty. The rash was brought on by any exertion and also by wind and cold weather. The disability became so great that the patient had been forced to abstain from activities enjoyed by normal girls; she could not attend dances, could not swim, could barely walk enough to attend school. The rash would be brought on several times daily and could be made to disappear only by the patient sitting perfectly still for from forty-five minutes to three hours. It was present the year round but was more severe in winter. The eruption consisted, in its mild phase, of a scarlet flush, soon followed by a red, diffuse, papular eruption. It usually was confined to the neck, face and arms, and it itched and burned excessively. If the patient did not become quiet immediately the condition became worse, more of the body became involved. Large typical, urticarial wheals appeared, the hands and wrists became swollen often enough to prevent closing the fists, the lips became swollen, and edema of the larynx would often produce some wheezing and a choking sensation. At this stage moderate dermatographia could be elicited. The disability coming as it did in adolescence and young adult life, caused the patient to become very self-conscious and easily embarrassed when in the company of others and embarrassment often would excite an eruption. The patient's father was a physician and many treatments had been tried and many attempts made to determine the exciting factor, but without success. Skin tests had all been negative. Elimination diets to seek out offending foods disclosed none to be the cause. Basal metabolic rates had been normal. Examination for foci of infection had all been negative. Many drugs had been tried without success. A few months previous to her admission at the clinic she had been given some Soricin (sodium ricinoleate) 5 grains (0.3 Gm.) three times a day, as advocated recently by Morris and Dorst,¹ to overcome bacterial sensitivity of the intestinal tract. For two or three weeks this treatment had seemed to help some, but it soon failed to give any relief. The patient's father had been subject to hay fever, but other than this the family history was negative.

At examination the young woman was found to be rather obese. Over the neck and face there was a mild papular eruption that had appeared after a short walk to the clinic. Two teeth were dead, although there was no evidence of periapical infection. The tonsils had been removed, but there was a small tonsillar tag on the left. Urinalysis, blood counts and differential blood counts all gave normal results. The serologic test for syphilis, performed on the blood, was negative. The basal

metabolic rate was —8 per cent. Blood pressure and pulse rates were normal. Puberty had occurred at the age of 13 years. Menstruation had occurred every four to six weeks, except for the two years just preceding her visit to the clinic, when flow had become regular at thirty-three days but was rather scant. She had had considerable dysmenorrhea since puberty. Skin tests with a wide variety of substances all gave negative results. Attempts to produce urticarial wheals by means of physical agents such as heat, cold and light resulted in a small wheal being produced with ice. None of the other agents caused any reaction.

Because of the fact that Soricin had seemed to give slight, temporary relief, and in spite of the fact that the patient had never had any intestinal symptoms (not even mild constipation), a culture was made of her stool and the predominating organisms were isolated. The standard bacteriologic procedure was employed, fishing the colonies from poured blood agar plates, and subsequently growing them as pure cultures in brain broth. Killed suspensions of the organisms, made up to a concentration of 500,000,000 in each cubic centimeter, were used for skin tests. Four organisms were isolated: streptococci that caused slight hemolysis, green-producing streptococci, *Escherichia coli* that was indifferent on blood agar, and *Escherichia coli* that was hemolytic.

Skin tests made on the volar surface of the left forearm with killed suspensions of these organisms resulted in no reaction from the streptococci but reaction graded 3 at the site of injection of both suspensions of *Escherichia coli*. The reactions consisted of large urticarial wheals surrounded by larger areas of erythema. There was no reaction at the site of the control injection of physiologic sodium chloride solution. A vaccine was made of equal parts of the two suspensions of *Escherichia coli*.

During the time required to produce the vaccine, the patient was given five subcutaneous injections daily of 0.1 mg. of histamine in an effort to determine whether desensitization by histamine could be produced as Horton and Brown had produced it in their work with cold allergy. This did not relieve the symptoms and was discontinued.

The patient was dismissed from the clinic September 15, to begin the treatment by vaccine at home. She was instructed to begin with 0.1 cc. taken subcutaneously twice weekly, increasing the dose by 0.1 cc. each time unless a local reaction occurred. If such reaction did occur, the dose was to be dropped and gradually increased again. A dose of 1 cc. was to be the maximum. The patient found that she never could exceed a dose of 0.6 cc. as a larger dose produced a large area of redness and swelling at the site of injection.

Within three weeks after she began the treatment with vaccine the patient's condition was markedly improved, and by the end of six weeks the urticaria had completely disappeared. She could walk and exercise with impunity for the first time since she had reached the age of 13 years. She gradually assumed the routine of taking 0.6 cc. of vaccine once weekly. About the last day of the week if she exerted herself, she would notice a little blush on her neck suggestive of the old eruption but it would leave immediately when she rested, and injection of the vaccine the next day would keep her completely relieved for the next six or seven days. In June, 1933, she was advised to discontinue taking the vaccine. She did this for two weeks, but the eruption began to return and she resumed the treatment. At present she is still taking the vaccine once weekly, with complete relief of symptoms, which makes almost one year of complete relief since the treatment was begun.

COMMENT

No attempt will be made here to explain this result. It will be interesting to trace the patient and see whether the relief is permanent as it bids fair to be after a year of relief. At any rate, the treatment involves practically no risk, is not expensive, and may well be tried in stubborn cases, when the exciting factor seems obscure.

From the Mayo Clinic. Dr. Emmett is a Fellow in Surgery of the Mayo Foundation and Dr. Logan is connected with the Division of Medicine of the Mayo Clinic.

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY OF THE AMERICAN MEDICAL ASSOCIATION HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT
H A CARTER Secretary

VICTOR ULTRAVIOLET MERCURY VAPOR QUARTZ LAMPS ACCEPTABLE

The General Electric X-Ray Corporation, 2012 Jackson Boulevard, Chicago, manufactures and offers for sale to the medical profession the following ultraviolet radiation generators

ALTERNATING CURRENT UNITS—AIR-COOLED

Model 'A' Mobile Unit with tubular column for reflecting hood mounted on rectifier control cabinet 115 or 230 volts 50 60 cycles Approximate shipping weight, 215 lbs (98 Kg)

Model A Air Cooled Quartz Lamp

base mounted on four casters 115 or 230 volts 50 60 cycles Approximate shipping weight 93 lbs (42 Kg)

WATER-COOLED—SELF CONTAINED

Model 'A' Mobile Unit with receptor for lamp mounted on rectifier control cabinet 115 or 230 volts 50 60 cycles Approximate shipping weight 220 lbs (100 Kg)

Model 'A' Mobile Unit with receptor for lamp counterweight suspended from curved overhead arm on rectifier control stand 115 or 230 volts 50 60 cycles Approximate shipping weight 275 lbs (125 Kg)

WATER COOLED—FAUCET TYPE

Model 'A' Mobile Unit with receptor for lamp mounted on rectifier control cabinet includes necessary attachments for plumbing connections 115 or 230 volts 50 60 cycles Approximate shipping weight 180 lbs (82 Kg)

Model 'A' Mobile Unit with receptor for lamp counterweight suspended from curved overhead arm includes necessary attachments for plumbing connections 115 or 230 volts 50 60 cycles Approximate shipping weight 235 lbs (107 Kg)

Model 'B' Wall Unit with hinged receptor for lamp mounted on wall includes wall bracket for control cabinet and necessary attachments for plumbing connections 115 or 230 volts 50 60 cycles Approximate shipping weight 140 lbs (64 Kg)

COMBINATION OUTFITS

Model 'A' Mobile Unit with self contained water-cooling system combining air-cooled lamp with water-cooled lamp Air-cooled reflector hood and receptor for water-cooled lamp mounted on rectifier control cabinet 115 or 230 volts 50 60 cycles Approximate shipping weight 295 lbs (134 Kg)

Model 'A' Mobile Unit with faucet water-cooling system combining air-cooled lamp with water-cooled lamp Air-cooled reflector hood and receptor for water-cooled lamp mounted on rectifier control cabinet Includes necessary attachments for plumbing connections 115 or 230 volts 50 60 cycles Approximate shipping weight 250 lbs (113 Kg)

Model 'B' Mobile Unit with faucet water-cooling system combining air-cooled lamp with water-cooled lamp Air-cooled reflector hood and receptor for water-cooled lamp mounted on hinged wall receptor Includes necessary attachments for plumbing connections 115 or 230 volts 50 60 cycles Approximate shipping weight 250 lbs (113 Kg)

The firm writes that the outfits listed above are inclusive of Ultrarc Quartz Tubes and Tungar Rectifier Bulbs (when required) While model A units are obtainable for operation on 25-49 cycle alternating current, order should so specify, as special wiring is required for these frequencies

DIRECT CURRENT UNITS—AIR-COOLED

Model 'B' Mobile Unit with control cabinet and tubular column for reflecting hood mounted on tripod base 110 or 230 volts Approximate shipping weight 190 lbs (86 Kg)

Model 'B' Ceiling Suspension Unit reflecting hood suspended from ceiling, control cabinet mounted on wall bracket Includes wall bracket for control cabinet does not include suspension pipe or ceiling socket 110 or 220 volts Approximate shipping weight, 130 lbs (59 Kg)

Model 'D' Mobile Unit with telescopic column for reflecting hood and transformer base mounted on four casters 110 or 220 volts Approximate shipping weight, 93 lbs (42 Kg)

WATER-COOLED—SELF-CONTAINED

Model 'A' Mobile Unit with receptor for lamp mounted on control cabinet 110 or 220 volts Approximate shipping weight 190 lbs (86 Kg)

Model 'A' Mobile Unit with receptor for lamp counterweight suspended from curved overhead arm on control stand 110 or 220 volts Approximate shipping weight, 245 lbs (111 Kg)

WATER-COOLED—FAUCET TYPE

Model 'B' Wall Unit, with hinged receptor for lamp mounted on wall includes wall bracket for control cabinet and necessary attachments for plumbing connections 110 or 220 volts Approximate shipping weight, 110 lbs (50 Kg)

COMBINATION OUTFITS

Model 'A' Mobile Unit with self contained water cooling system combining air cooled lamp with water cooled lamp Air cooled reflector hood and receptor for water cooled lamp mounted on control cabinet 110 or 220 volts Approximate shipping weight, 265 lbs (120 Kg)

Model 'B' Mobile Unit with faucet water cooling system, combining water cooled lamp with air-cooled lamp Air-cooled reflector hood and control cabinet mounted on tripod base water cooled lamp on hinged wall receptor Includes necessary attachments for plumbing connections 110 or 220 volts Approximate shipping weight 220 lbs (110 Kg)

The Council has investigated several of these ultraviolet radiation generators, both of the air cooled and water-cooled type, and has found the mechanical make-up and physical characteristics of them satisfactory

The General Electric Air-Cooled Mercury Vapor Arc Lamps model A, can be operated on an arc voltage of from 70 to as high as 90 The current consumption, when operated on 70 volts, is 3½ amperes As the arc voltage is raised to 90 there is no appreciable increase in the current remaining practically constant at 3½ amperes

The model B Air-Cooled Mercury Vapor Arc Lamps can be operated on an arc voltage of from 70 to 80 the current consumption being 3½ amperes

Model A Water Cooled Quartz Lamp

In the case of the air cooled lamps the time for a first degree erythema on an average skin at a distance of 30 inches is on the average 30 to 45 seconds when operating on an arc voltage of 70 If for example the arc voltage of the model A lamp is raised to 90 it will produce a first degree erythema on an average skin at a distance of 30 inches in approximately 15 to 30 seconds

The General Electric Water Cooled Quartz Mercury Lamps are designed to operate on an arc voltage of 50 the current consumption at this voltage being approximately 3.3 amperes

A minimum perceptible erythema may be produced on contact with the average skin in about fifteen seconds

The Council on Physical Therapy declares the ultraviolet generators, manufactured by the General Electric X-Ray Corporation, eligible for inclusion in the list of accepted devices

Council on Pharmacy and Chemistry

REPORTS OF THE COUNCIL

THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING STATEMENT
PAUL NICHOLAS LEECH Secretary

ANTIPNEUMOCOCCUS SERUM CONTAINING TYPE II ANTIBODIES

In 1924 the Council omitted all antipneumococcus serums containing type II antibodies, on the ground that the therapeutic efficacy of this organism had not been demonstrated. Preparations containing type I antibodies have been retained since that time. Recently there has been brought to the Council's attention evidence that with improved preparations and technique the experimental use of type II antibodies or of preparations containing this antibody in combination with type I is justified. The Council therefore voted to consider the acceptance of brands of antipneumococcus serum containing type II and voted to inform firms manufacturing the antipneumococcus serum of this decision.

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

PAUL NICHOLAS LEECH Secretary

ANTIPNEUMOCOCCUS SERUM (Sec New and Non-official Remedies, 1933, p. 369)

Lederle Laboratories, Inc., Pearl River, New York

Antipneumococcus Serum Refined and Concentrated Types I and II—Prepared by immunizing horses with intravenous injections of cultures of type I and type II pneumococci. When test bleedings show the serum to have reached a sufficient degree of potency for types I and II pneumococci the horses are bled aseptically and the serum is refined and concentrated by the method described by Lloyd D. Felton (*J. Infect. Dis.* December 1928, p. 543). The usual sterility and safety tests are made by injection into white mice and guinea pigs. The potency of the product is expressed in terms of the unit described by Felton (*Boston M. & S. J.* May 15, 1924, p. 819; *J. Infect. Dis.* September 1925, p. 199; October 1925, p. 309) and used by Park. While the unit originally was intended to be the amount of antibody that will protect against one million fatal doses of culture it has lately been taken to be 1/200 cc of the control serum (F 146) distributed by Dr. Felton. Marketed in packages of one syringe containing 10,000 units each of types I and II and in packages of one syringe containing 20,000 units each of types I and II each accompanied by a vial of normal horse serum (1:10 dilution) for the conjunctival test.

Dosage—Intravenously first dose 10,000 units of each type followed by a second dose of 20,000 units of each type in one hour; the second dose may be repeated at intervals of from four to six hours until the temperature falls and beneficial effects are evident.

Antipneumococcus Serum Refined and Concentrated Type II—Prepared by immunizing horses with intravenous injections of cultures of type I and type II pneumococci. When test bleedings show the serum to have reached a sufficient degree of potency for type II pneumococcus the horses are bled aseptically and the serum is refined and concentrated by the method described by Lloyd D. Felton (*J. Infect. Dis.* 43:543 [Dec.] 1928). The usual sterility and safety tests are made by injection into white mice and guinea pigs. The potency of the product is expressed in terms of the units described by Felton (*Boston M. & S. J.* 190:819 [May 15] 1924; *J. Infect. Dis.* 37:199 [Sept.] 1925; 37:309 [Oct.] 1925) and used by Park. While the unit originally was intended to be the amount of antibody that will protect against one million fatal doses of culture it has lately been taken to be 1/200 cc of the control serum (F 146) distributed by Dr. Felton. Marketed in packages of one syringe containing 10,000 units and in packages of one syringe containing 20,000 units each accompanied by a vial of normal horse serum (1:10 dilution) for the conjunctival test.

Dosage—Intravenously first dose 10,000 units followed by a second dose of 20,000 units in one hour; the second dose is repeated at intervals of three to four hours until the temperature falls and beneficial effects are evident.

Committee on Foods

THE COMMITTEE HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORTS
RAYMOND HERTWIG Secretary

NOT ACCEPTABLE

GENUINE BUTTER-NUT BREAD (SLICED)

The L. D. Feuchtenberger Bakeries, Bluefield, W. Va., submitted to the Committee on Foods a white bread called 'Genuine Butter-Nut Bread (Sliced)' composed of patent flour, water, sweetened condensed skimmed milk, sucrose, lard, salt, malt syrup, yeast and a yeast food containing calcium sulphate ammonium chloride, sodium chloride and potassium bromate.

Discussion of Name—The name "Butter-Nut Bread" implies that the bread contains either butter and nuts or butternuts and in such quantity as to give the product distinctive physical and nutritional characteristics because of such ingredients and different from those of customary white bread. The baking formula does not contain butter, nuts or butternuts. The name is considered inappropriate, misinformative and misleading.

The manufacturer when informed of this opinion expressed himself as unwilling to change the name in accordance with the Committee's recommendations. This bread will therefore not be listed among the Committee's accepted foods.

NOT ACCEPTABLE

DR. BROOKS' CACAO LIQUOR

The Beacon-Gale Corporation, New York, submitted to the Committee on Foods a cacao liquor or chocolate called 'Dr. Brooks' Cacao Liquor'.

Discussion of Name—Food names containing the name of a doctor or including the title "Dr." lend themselves to misleading medicinal, quack-medical or therapeutic advertising. The names suggest medicinal uses or therapeutic values for the food. Advertising copy writers are prone to take advantage of such names and at least give medicinal implications to the advertising. Since such names are strong incentives to inappropriate advertising, their use for foods is to be discouraged. An appropriate name for this chocolate liquor is "Brooks Chocolate Liquor."

The manufacturer was informed of this opinion but has expressed himself as unwilling to change the name in accordance with the Committee's recommendations. This product will therefore not be listed among the Committee's accepted foods.

ACCEPTED FOODS

THE FOLLOWING PRODUCTS HAVE BEEN ACCEPTED BY THE COMMITTEE ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION FOLLOWING ANY NECESSARY CORRECTIONS OF THE LABELS AND ADVERTISING TO CONFORM TO THE RULES AND REGULATIONS. THESE PRODUCTS ARE APPROVED FOR ADVERTISING IN THE PUBLICATIONS OF THE AMERICAN MEDICAL ASSOCIATION AND FOR GENERAL PROMULGATION TO THE PUBLIC. THEY WILL BE INCLUDED IN THE BOOK OF ACCEPTED FOODS TO BE PUBLISHED BY THE AMERICAN MEDICAL ASSOCIATION.

RAYMOND HERTWIG, Secretary

MCCORMICK'S BEE BRAND VANILLA EXTRACT

Manufacturer—McCormick & Company, Inc., Baltimore

Description—Vanilla extract containing water, alcohol, sugar, and extractive matter of Mexican vanilla beans.

Manufacture—Mexican vanilla beans are warmed in an oven or in the sun and are packed in cases wrapped in blankets or matting, to induce "sweating" or fermentation. After a definite period the beans, while still warm, are removed from the cases and dried on frames in the sun. This procedure of alternate sweating and drying is repeated many times to develop the desired flavor, taking from four to six months. The beans become dark and lose moisture during the treatment. They are exported in wooden cases.

For preparing the extract at the American plant the beans are chopped, macerated in a menstruum of 95 per cent alcohol, water and sugar, and then percolated with the same solution, the extract is stored for from six to twelve months, filtered, and bottled

Analysis (submitted by manufacturer) —

	per cent
Water by volume	57.3
Alcohol by volume	42.1
Total solids	8.0 Gm per 100 cc
Ash	0.4 Gm per 100 cc
Sucrose	4.9 Gm per 100 cc
Vanillin	0.24 Gm per 100 cc
Lead number (Winton)	0.67

Claims of Manufacturer—Conforms to definition and standard for vanilla extract of the United States Department of Agriculture

BEECH-NUT STRAINED GREEN BEANS

(SLIGHTLY SEASONED WITH SALT)

Manufacturer—Beech-Nut Packing Company, Canajoharie, N Y

Description—Sieved green beans retaining in high degree the natural vitamin and mineral values, seasoned with salt

Manufacture—Fresh green beans are thoroughly washed and cleaned, stem and blossom ends are removed by hand. The subsequent treatment and processing are the same as for Beech-Nut Strained Carrots (THE JOURNAL, Nov 11, 1933, p 1562)

Analysis (submitted by manufacturer) —

Vitamins and Claims of Manufacturer—See Beech-Nut Strained Carrots (THE JOURNAL, Nov 11, 1933, p 1562)

FLOG BRAND EVAPORATED MILK

Packer—The Page Milk Company, Merrill Wis

Distributor—Ridenour Baker Grocery Company, Kansas City, Mo

Description—Canned, unsweetened evaporated milk, the same as Page Evaporated Milk Sterilized Unsweetened (THE JOURNAL, May 30, 1931, p 1872)

1 FANT'S FAMOUS FLOUR (MATURED, BLEACHED) 2 X-CEL FLOUR (MATURED, BLEACHED)

Manufacturer—Fant Milling Company, Sherman, Texas

Description—1 Long patent' hard wheat flour bleached
2 Long patent' flour prepared from soft and hard wheats, bleached

Manufacture—Selected wheat is cleaned scoured tempered and milled by essentially the same procedures as described in THE JOURNAL June 18, 1932 p 2210. Chosen flour streams are blended and bleached with nitrogen trichloride (from 1.5 to 3 Gm per barrel) and with benzoyl peroxide and calcium phosphate (1 part to 50,000 parts of flour) and automatically packed in bags

Claims of Manufacturer—All purpose flours for home baking

1 G A GOLDEN TABLE SYRUP

(CORN SYRUP FLAVORED WITH REFINERS SYRUP)

Packer—Wheeler Barnes Company, Minneapolis

Distributor—Independent Grocers Alliance Distributing Company, Chicago

Description—Table syrup, corn syrup base (85 per cent) with refiners' syrup (15 per cent), the same as Golden Oak Brand Amber Syrup (THE JOURNAL, Dec 3, 1932, p 1948)

HIRES ROOT BEER CARBONATED BEVERAGE

Manufacturer—The Charles E Hires Company, Philadelphia

Description—Carbonated root beer extract beverage prepared under license by Charles E Hires Company, containing carbonated water, sucrose, and "Hires Root Beer Extract" or "Hires Root Beer Extract Bottlers' Solution," which is similar in composition to "Hires Root Beer Concentrated Extract" excepting for the quantity of caramel ingredient (Hires Root Beer, THE JOURNAL, Aug 13, 1932, p 563)

Manufacture—The carbonated beverage is prepared under license grants, the licensee is contracted to use the prescribed formula and method of preparation and advertising prepared under the direction of the Hires Company. That company makes a number of inspections each year of the licensee's plants and method of merchandising

Analysis (submitted by manufacturer) —

	per cent
Moisture	89.6
Total solids	10.4
Ash	0.1
Fat (ether extract)	0.0
Protein (N \times 6.25)	0.0
Sucrose (copper reduction method) (immediately after bottling)	9.3

Calories—0.4 per gram, 11 per ounce

Claims of Manufacturer—A refreshing carbonated root beer extract beverage

WEIDEMAN BOY BRAND TOMATO JUICE

Packer—Vincennes Packing Corporation, Vincennes, Ind

Distributor—The Weideman Company, Cleveland

Description—Pasteurized tomato juice with added salt, retains in high degree the natural vitamin content, the same as Alice of Old Vincennes Tomato Juice (THE JOURNAL, Feb 20, 1932, p 640)

POSTUM

Manufacturer—Postum Company, Inc, New York

Description—Roasted blend of bran, wheat, molasses and malted wheat flour

Manufacture—Bran, malted wheat flour and molasses are blended in definite proportions, roasted, admixed with roasted wheat, ground and automatically packed

Analysis (submitted by manufacturer) —

	per cent
Moisture	10
Ash	5.9
Fat (ether extraction method)	2.7
Protein (N \times 6.25)	12.3
Crude fiber	9.5
Carbohydrates other than crude fiber (by difference)	68.6

Calories—3.5 per gram 99 per ounce

Claims of Manufacturer—For the preparation of table beverage with water or milk. Contains no stimulating ingredient

LILY CAREY-IZED TABLE SALT

PIONEER CAREY-IZED TABLE SALT

PREMIUM SIFTED CAREY-IZED TABLE SALT

1 PER CENT MAGNESIUM CARBONATE ADDED
TO PREVENT CAKING

Manufacturer—The Carey Salt Company, Hutchinson, Kan

Description—Table salt containing approximately 1 per cent added magnesium carbonate. The same as "Carey's Salt (Free Running)" (THE JOURNAL, Aug 26 1933 p 676)

Claims of Manufacturer—For table and cooking uses of salt. The added magnesium carbonate tends to preserve the free running' qualities. Does not cake or harden in the package

SWIFTS STERILIZED FLAVORED MILK

Packer—Libby McNeill & Libby, Chicago

Distributor—Swift and Company, Chicago

Description—Canned unsweetened evaporated milk the same as Libby's Sterilized Unsweetened Evaporated Milk (THE JOURNAL, June 13, 1931 p 2037)

SATURDAY, DECEMBER 16, 1933

THE HAZARDS OF DRY CLEANING

One of the innovations of modern life is the widespread use of dry cleaning. This involves the employment of a variety of organic substances (in contrast with the familiar cleansing soap and water) that act as solvents of stains and detergents for dirt. A number of hazards may attend the use of the newer "dry cleaning solvents." Most of them are quite volatile and many present fire hazards because of their explosive or inflammable character. From this point of view the danger of burns, which already besets mankind in increasing degree, is additionally multiplied. A second possibility of harm lies in the effects of some of the cleanser solvents on the skin of the hands. This applies particularly to dry cleaning in the home, where the immersion of garments by hand into the cleanser is part of the usual routine of use. A further menace resides in the toxicity of the vapors that are almost inevitably encountered where the cleansing solvents are used.

According to a recent study¹ of the problem of dry cleaning, particularly as it relates to the home, more than fifty solvents sold for the purpose of cleaning fabrics at home by immersion were found to consist of one or more of the following organic liquids: carbon tetrachloride, chloroform, trichlorethylene, ethylene dichloride, propylene dichloride, benzene, toluene, ether, alcohol and petroleum distillates of various degrees of volatility. This is a formidable list of "dangerous chemicals" for any physician to contemplate, and it at once conjures up risks to human well being in more than one way. From the point of view of fire underwriters' hazards, the following points are taken into consideration in each case: volatility, ignition temperature, flammable or explosive limits, combustion intensity, vapor density, toxicity, nature or products of combustion, and nature of products of decomposition on storage or heating. Some of the compounds used, notably carbon tetrachloride and trichlorethylene, are noncombustible and nonflammable. Unfortunately, some

of the commercial proprietary products sold for the home are conspicuously labeled as nonexplosive. The report states that this is misleading to the housewife, who is likely to think that the term implies nonflammability. It is also incorrect in the strict sense of the word, since solvents of this type might explode under some circumstances. Various testing laboratories report petroleum distillates of this range as semexplosive.

The underwriters' laboratories also mention that the toxicity of a substance is recognized as having an indirect bearing on the fire hazard involved in the use of the product. The reason given for this is that a toxic substance, by contact with the skin or through inhalation, may act on the body of the person using it in such a way as to incapacitate or drive him away, thereby introducing a serious hazard in case of fire. It is reported, further, that some of the secret mixtures advertised as nonexplosive are made of gasoline and a nonflammable chemical. A fault of these solvents is that the added chemicals evaporate more quickly during use than does the gasoline, which leaves the fluid practically nothing but gasoline. Experience shows that the promiscuous sale of motor fuel for home dry cleaning is not uncommon. The study points out that warnings are rarely given. The purchase of gasoline at a filling station may also involve a hazard other than fire—that of tetra-ethyl lead poisoning. Present methods of obtaining gasoline at filling stations make it possible for the purchaser to obtain gasoline containing tetra-ethyl lead without being aware of the presence of this ingredient. Since tetra-ethyl lead is one of the few compounds definitely known to be poisonous merely by absorption through the skin, the dangers of handling gasoline containing this substance (aside from the fire hazard) cannot be overestimated.

As far as the local effects of the cleaner solvents are concerned, all of them were found, as might be expected, to have the effect of removing oil from the skin, thus causing it to become chafed and cracked, particularly around the fingernails. The open vessel method caused much worse chafing than did the closed vessel method, although, even in the latter case, immersion of the hands in the solvent was found to be necessary in removing and squeezing the fabrics. There appeared to be little difference between the drying and chafing action of the various solvents on the hands. The effect of toxicity due to absorption of some of these compounds, notably in the form of vapors through the lungs, obviously varies under the diversity of conditions that may arise in the cleansing process. The amount of volatile ingredients reaching the respiratory tissues will depend on the degree of protection afforded by ventilation, the vaporizing potencies of the compound used, and the individual caution to avoid inhalation of "fumes." Such substances as naphtha and petroleum benzine, as well as other volatile petroleum distillates, may exert a baneful influence on the

¹ Mack, Pauline B. Kessinger, Polly B. Ottinger, Elsa I. and Deck, Mary E. Home Dry Cleaning Solvents. *J. Home Economics* 25: 789 (Nov.) 1933.

nervous system,² and gasoline fumes cannot be endured long with impunity.³ According to Mack and her co-workers,¹ the heavier petroleum distillates decrease in toxicity with a decrease in their volatility, although cases of skin lesions leading to acne and eczema are known to result from contact of these products with the skin over a long time. They assert that, aside from its acute effects, carbon tetrachloride is known to produce chronic ills in persons breathing only small quantities of its vapors through considerable periods. The compound appears to have a particularly deleterious effect on liver and kidney tissues, some of the latter of which cannot be rejuvenated, once destroyed. Just how large an amount of the solvent is needed or how many and how long the periods of inhalation must be in order to produce chronic hepatic and renal ailments, however, is not now known. All chlorinated hydrocarbons are known to have both acute and chronic deleterious effects on the human organism. Concerning the amounts of such compounds as ethylene dichloride, propylene dichloride, or trichlorethylene needed to become dangerous, even less is known than in the case of carbon tetrachloride. The toxicity of benzene and related compounds has long been familiar.

Dry cleaning, though still practiced extensively in the home, has become a public business of large magnitude in recent times. This seems to be a rather fortunate development. Industrial management is learning to consider the hazards to which the worker in plants is exposed, and in many instances the newer laws and other modes of regulation make imperative suitable precautions to protect those employed. In the home, on the other hand there is less urge to guard against the menaces, and in many—perhaps most—instances there is no thought whatever of dangers well recognized in industrial plants. As evidence one may cite the appalling number of deaths from the inhalation of exhaust gases in garages attached to homes. Part of the lack of protection in the case of home dry cleaning solvents lies in the secret character of the vended products and the lack of adequate warnings on their labels. Probably the dangers will gradually become minimized by the growing abandonment of home cleaning in favor of commercial plants. The economic aspect of this change of practice will probably militate less and less against the latter. The recent study,⁴ dealing as it did with the economy as well as the cleaning efficiencies of the various solvents, showed some unexpected outcomes. The cost of doing dry cleaning at home was found to be greater than is commonly supposed and the cleaning efficiencies of the various solvents proved to be low. The retail prices of many of the secret preparations were found to be high as compared with the actual cost of their ingredients. It was found that many of the preparations had not been sent to a recognized

laboratory to be examined for the fire hazard, and that even those which had been so examined did not carry on their labels a definite statement as to their degree of fire hazard. The presence of ingredients believed to be toxic even if handled in gallon quantities was revealed in many of the secret trade preparations. These were found in most cases to be accompanied by inadequate directions.

THE OUTLOOK IN NUTRITION

A survey of progress made in the science of nutrition during the past two decades serves to emphasize the tremendous sum total of effort expended by investigators in this field. Not only have many earlier observations been explained but unexpected relations have been established between nutrition and biologic function in lower forms of organisms as well as in man. Not the least of the accompanying phenomena is the widespread popular interest in nutrition, especially in some of its more novel features. A careful consideration of the broad scope and at the same time the logical detail of current knowledge of nutrition leads one to speculate on the direction which future effort will take in this field. In a recent discussion by Mendel¹ there has been brought to bear on this question the keen analysis and seasoned judgment of a pioneer investigator.

Attention is called to the influence, both direct and indirect, of the World War on nutrition. Not only were practical problems of the broadest scope presented for solution during that period, but before much time had elapsed it was acknowledged that the most valuable help came from those professionally trained in this field. Again, under the urge of national edicts the individual inevitably examined his personal dietary in the light of information which for the first time was by design made common property. The result of this large scale tutelage is a familiarity with at least some of the fundamental principles of nutrition on the part of a considerable portion of the population, food economics have been greatly influenced during the post-war period and individuals have not hesitated to alter their own dietary habits in order to conform to certain standards of physique or of alleged propriety.

Attention is further called by Mendel to the lack of current interest among investigators in what he calls "alimentation." By examining in detail a few of the accepted concepts regarding transformations in the gastro-intestinal tract, he points out the many uncertainties and actual gaps in the knowledge of secretion, digestion and absorption. For instance, "it must be frankly admitted that no adequate 'balance sheet' has ever been submitted for the disposal of digested and absorbed fat." There is likewise the suggestion that it would be profitable to reinvestigate the mode of entrance of the products of digestion of proteins into

¹ Hamilton, Alice. In a trial paper in the United States New York Macmillan Company, 1925, pp. 407-479.

⁴ Mendel, L. B. *Science* 78: 317 (Oct. 13) 1933.

the blood. Citing the recently demonstrated functions of the "trace" elements in nutrition, he directs emphasis toward the number of unusual, apparently adventitious, substances consumed by the individual, compounds occurring in plant and animal cells, the functions of most of which have as yet received scant attention.

In discussing the future of nutrition, the Yale investigator thus urges a reexamination of some of the fundamental tenets of the science, but in light of progress in thought as well as in increased precision of methods. This inevitably means a wider use of experimental animals supplemented with the best of microchemical technology.

FIBRINOLYTIC STREPTOCOCCI

Hemolytic streptococci of human origin are apparently unique among the pathogenic bacteria of clinical interest, since they invariably possess the property of rapidly dissolving or liquefying human fibrin. This lytic property may account in part for the ability of the streptococcus to invade tissues. A simple method for the determination of the fibrinolytic action of bacteria or of bacterial filtrates was developed by Tillett and Garner¹ of Johns Hopkins University School of Medicine. The technic consists in the addition of 0.5 cc. of a broth culture of the micro-organism to be tested to 1 cc. of 20 per cent oxalated human plasma. Coagulation is induced by the addition of 0.25 cc. of 0.25 per cent calcium chloride solution and the tubes are immediately placed in a water bath at 37.5 C. Slight fibrinolysis is shown by a softening and release of the clot from the sides of the tube. With complete lysis, all visible evidence of fibrin disappears from the mixture. Tubes in which the clot is still unsoftened and firmly adherent at the end of twenty-four hours are considered negative.

Twenty-eight strains of hemolytic streptococci of human origin were tested by the Baltimore physicians. These included strains isolated from scarlet fever, septicemia, erysipelas, tonsillitis, acute nephritis and otitis media. All these strains promptly and completely liquefied the routine human plasma clot, in most cases the lysis being complete within fifteen minutes. In no case was complete liquefaction delayed more than forty or fifty minutes. In contrast with this dramatic reaction, fifteen strains of hemolytic streptococci of non-human origin were completely nonfibrinolytic with their technic, a firm and apparently unaltered plasma clot being demonstrable at the end of twenty-four hours. These strains included streptococci isolated from the cow, horse, rabbit and guinea-pig. Three other animal strains, however, did give positive Tillett-Garner reactions. A large number of other bacterial species were also tested and invariably found to be fibrinolytically negative. These included such micro-organisms

as *Streptococcus viridans*, *Pneumococcus*, *B. typhosus*, *B. coli*, *B. dysenteriae* and the influenza bacillus. The only other bacterial species thus far found to possess the Tillett-Garner lytic property were certain strains of the staphylococcus, which occasionally caused a slight softening of the human plasma clot if the reaction was allowed to continue for from eighteen to twenty-four hours.

The Tillett-Garner lytic action of hemolytic streptococci is at least relatively specific for human fibrin. No trace of clot liquefaction is demonstrable with rabbit fibrin. Other animal fibrins have not yet been tested. This observation is of basic interest in bacteriologic research. It suggests that many results of streptococcus research on rabbits, and possibly on other lower animals, are not applicable to human disease. The fibrinolytic agent formed by the clinically pathogenic hemolytic streptococcus is apparently a soluble enzyme or toxin, since it is demonstrable in apparently full titer in cell-free, sterile broth filtrates. An active anti-fibrinolytic immunity is demonstrable in the serum of patients who have recovered from acute hemolytic streptococcus infections. The possibility of a local therapeutic use of the Tillett-Garner lysin as an in vivo solvent of fibrinous exudates has not yet been tested. Whether or not antistreptococcus horse serum will neutralize the Tillett-Garner lytic factor has also not yet been determined.

Current Comment

PIMENTO PEPPERS AND VITAMIN A

The pimento pepper is now widely used as a condiment, especially in salads, the bright red flesh is decorative and adds a mildly piquant flavor to the food mixture. As a result of nutritional studies there has gradually developed a tacit assumption that highly colored natural food materials are likely to possess more or less unusual nutritive advantages. It is of particular interest, therefore, that Ascham¹ has recently demonstrated that the pimento pepper is rather prominent among vegetable products as a source of vitamin A. A few milligrams daily of the dried material suffices to promote excellent growth in experimental animals consuming a ration otherwise devoid of this factor. The vitamin potency of the dried fruit is of the order of magnitude of that of good cod liver oil and far above that of butter. In the form (canned) ordinarily used, pimentos are as rich in vitamin A as are carrots and somewhat richer than is butter. Expressing the vitamin A assay in conventional terms, somewhat less than 20 mg. of canned pimento contains approximately 1 unit. A determination of the carotene content of this variety of pepper indicated that 2 mg. of the dried material contained somewhat more than 0.5 microgram. As it has been previously shown that 0.5 microgram of carotene is roughly equivalent to 1 unit of vitamin A, it appears that virtually all the vitamin A

¹ Tillett, W. S. and Garner, R. L. J. Exper. Med. 58: 485 (Oct.) 1933.

¹ Ascham, L. Bull. Georgia Expt. Sta. 177, September 1933.

potency of the pimento arises from the carotene contained in it. This agrees with other recent evaluations of fruits² and emphasizes a distinction, currently made, between the vitamin A potency of plant and of animal materials, that of the former being due largely to carotene whereas, in the latter, the pigment accounts for only a minor part of the vitamin A potency.³

Association News

MEDICAL BROADCAST FOR THE WEEK

Talk over Network of the National Broadcasting Company

The American Medical Association broadcasts each Monday afternoon from 1:30 to 1:45 Eastern standard time (12:30 central standard time). The subject for Monday, December 18, is "Have a Safe and Happy Christmas." The speaker will be Dr. W. W. Bauer, director, Bureau of Health and Public Instruction, American Medical Association. Subjects and speakers for subsequent broadcasts will be announced weekly in THE JOURNAL.

The following additional stations have signified their intention of accepting the program: WCAE, Pittsburgh; WFI, Philadelphia; and WCSH, Portland, Maine.

Radio Talks from Station WBBM

The American Medical Association broadcasts on Tuesday and Thursday mornings from 8:55 to 9 o'clock, central standard time, over Station WBBM (770 kilocycles, or 389.4 meters).

The subjects for the week are as follows:

December 19 Indigestion
December 21 Your Nose—Inside and Out

There is also a fifteen minute talk sponsored by the Association on Saturday morning from 9:45 to 10 o'clock over Station WBBM.

The subject for the week is as follows:

December 23 What Is a Mastoid?

THE CLEVELAND SESSION

Chairmen of Section Committees to Assist in Promotion of Section Exhibits

The fifteen sections of the Scientific Assembly have appointed exhibit committees to assist in the promotion of section exhibits at the Cleveland Session and in the coordination of activities between the Scientific Assembly and the Scientific Exhibit. Chairmen of the section exhibit committees are as follows:

PRACTICE OF MEDICINE

Irving S. Wright, New York

SURGERY, GENERAL AND ABDOMINAL

Alton Ochsner, New Orleans

OBSTETRICS, GYNECOLOGY AND ABDOMINAL SURGERY

L. D. Plase, Iowa City

OPHTHALMOLOGY

Thomas D. Allen, Chicago

LARYNGOLOGY, OTOTOLOGY AND RHINOLOGY

William A. Mullin, Cleveland

PEDIATRICS

F. Thomas Mitchell, Memphis

PHARMACOLOGY AND THERAPEUTICS

Russell I. Haden, Cleveland

PATHOLOGY AND PHYSIOLOGY

W. C. McCarty, Rochester, Minn.

NERVOUS AND MENTAL DISEASES

Groves B. Smith, Godfrey, Ill.

DERMATOLOGY AND SYPHILOLOGY

Fred D. Weidman, Philadelphia

PREVENTIVE AND INDUSTRIAL MEDICINE AND PUBLIC HEALTH

Paul A. Davis, Akron, Ohio

UROLOGY

Russell S. Ferguson, New York

ORTHOPEDIC SURGERY

E. B. Mumford, Indianapolis

GASTRO-ENTEROLOGY AND PROCTOLOGY

A. H. Aaron, Buffalo

RADIOLOGY

S. W. Donaldson, Ann Arbor, Mich.

Application blanks for space in the Scientific Exhibit may be obtained from any of the foregoing chairmen or from the Director, Scientific Exhibit, 535 North Dearborn Street, Chicago.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC.)

CALIFORNIA

Beaumont Celebration—A joint meeting of the Los Angeles County Medical Association and the Barlow Medical Library, December 5, commemorated the one hundredth anniversary of the publication of William Beaumont's "Experiments and Observations on the Gastric Juice and the Physiology of Digestion." Dr. George Dock, Pasadena, president of the medical library association, discussed the Beaumont collection at St. Louis; Dr. Rolla G. Karshner, Los Angeles, Beaumont's life, and Harry Deuel, Jr., Ph.D., Los Angeles, the book. There was a display of first and second editions of the volume and photostatic copies of letters of Dr. Beaumont and Alexis St. Martin, and of Dr. Beaumont's diary.

Society News—Dr. Roy F. Nelson, Oakland, discussed "Peroral Endoscopy—Its Place in Medical Practice" before the Alameda County Medical Association, November 20. At a meeting of the Pacific Physical Therapy Association in Hollywood, November 15, the speakers included Dr. George S. Sharp, Pasadena, on "Diagnosis and Treatment of Superficial Cancer." The Society for Neurology and Psychiatry, Los Angeles, was addressed, November 22, among others by Drs. Karl A. Menninger, Topeka, Kan., and Howard L. Updegraff on "Psychoanalytic Aspects of Plastic Surgery." Dr. Hugh Cabot, Rochester, Minn., speaks today before the Medical Symposium Society of Los Angeles, on "Effect of Drainage of the Kidney by Nephrostomy on the Recovery of Kidney Function." Dr. P. K. Ito, president Japanese Medical Association, was one of the guest speakers before the International Medical Club in Los Angeles, November 24. A joint meeting of Los Angeles County medical and dental associations will be addressed, December 19, by Dr. Edward C. Rosenow, Rochester, Minn., on relation of focal infection and elective localization of streptococci in the causation of disease. The fourth annual conference of mosquito abatement officials in California was held in Berkeley, December 12. Dr. Hugh Cabot, Rochester, Minn., presented a historical review of the development of prostatectomy with an appraisal of present methods before the San Francisco County Medical Society, December 11.

COLORADO

Society News—At a meeting of the Medical Society of the City and County of Denver, December 5, Dr. Harry Gauss and Clough T. Burnett discussed "Interrelationship between Gastrointestinal and Renal Disease" and "Cardiovascular Syphilis" respectively, and Dr. Thaddeus P. Sears reported a case of hyperparathyroidism. A symposium on cancer of the breast was presented before the society November 21 by Drs. William W. Haggart, John E. Struthers, William W. Williams, Harry S. Finney, and William Walter Wasson.

Morgan, Agnes F. and Maden, Evelyn O. J. Nutrition 6: 83 (Jan.) 1951
Baumner, C. A. and Seerbeck, Harry. J. Biol. Chem. 101: 547 (Feb.) 1934
Shrenk, C. L. and Brasell, H. R. Ibid. 101: 701 (Apr.) 1934

CONNECTICUT

Thousands of Roentgenograms—Since the Connecticut State Health Department initiated its tuberculosis campaign in October, more than 12,000 children have had roentgenograms made. Because of the demands of the communities to have this work done, a second x-ray unit was placed in operation, November 9. The program, which is under way in more than 100 cities and towns in the state, is a joint effort to detect tuberculosis in the early stages sponsored by the state department of health, the state medical society, the state board of education and the state tuberculosis commission.

DISTRICT OF COLUMBIA

University News—Dr James W Jobling, professor and executive officer, department of pathology, Columbia University College of Physicians and Surgeons, delivered the November lecture of the Smith-Reed-Russell series at George Washington University School of Medicine, on arteriosclerosis. William W Cort, Ph D, Baltimore, gave the October lecture on "Recent Developments in Our Knowledge of Hookworm Disease."

Society News—Speakers before the George M Kober Medical Society, November 20, were Drs Hugo Einstein on "Hydronephrosis and Hydro-Ureter" and Lewis B Hill, Baltimore, "Psychiatric Aspects of Essential Hypertension."—Dr Alexander Bruno of the American Hospital in Paris addressed the District of Columbia Tuberculosis Association, Washington, October 30.—Dr Dean Lewis, Baltimore delivered an address in the Army Medical Center, November 20, on "Diagnostic Failures and Their Lessons."

ILLINOIS

University News—Forty staff members of the University of Illinois College of Medicine, Chicago, visited the Urbana campus, November 17, and were addressed, among others by George L Clark, Ph D, on researches of medical interest from the x-ray laboratory, Elmer Roberts, Ph D, genetic studies on inheritance of resistance to bacterial infection, and Frederic R Steggerda, Ph D, absorption and excretion in the colon.

Society News—Dr Max Thorek, Chicago addressed the McHenry County Medical Society, November 16, on "Nonsurgical Treatment of Osteomyelitis."—At a meeting of the Peoria City Medical Society, November 21, Brod O Barnes, Ph D, Chicago, discussed "Studies on the Pituitary Especially Related to Diabetes."—The McDonough County Medical Society was addressed in Macomb, November 14 by Drs Frank J Jurka and John J McShane, Springfield, on epidemic encephalitis and scarlet fever control respectively. Mr S V Layson discussed milk sanitation. All represented the state health department.—Dr William J Benner, Anna, was chosen president of the Southern Illinois Medical Association at its fifty-ninth annual meeting in Centralia, November 3. Dr Ben Fox, West Frankfort was named secretary, and Mount Vernon designated as the place for the next annual meeting. Speakers included Drs Vitray P Blair and Harry S Crossen, St Louis, Walter C Alvarez, Rochester, George T Palmer, Springfield, Andy Hall, Mount Vernon, William H Smith, Benton, and Philip H Kreuscher, Chicago.—At a meeting of the La Salle County Medical Society in La Salle, November 23, the speakers were Drs John T Murphy, Toledo, Ohio, and Vincent J O'Connor, Chicago, on "Cancer of the Ovary" and "Recent Advances in the Field of Genito-Urinary Surgery," respectively.

Chicago

Dr Lewis's Lecture at Northwestern—Dr Dean Lewis, Baltimore, President, American Medical Association, will give an address, December 19, in Thorne Hall, Northwestern University Medical School, under the auspices of Pi Kappa Epsilon Fraternity. The subject will be "Tumors of the Sympathetic Nervous System and Their Clinical Syndromes."

Dr Lahey to Lecture on Goiter—Dr Frank H Lahey, Boston, will present a symposium on goiter before the Chicago Medical Society, December 20. He will speak on "Diagnosis and Management of Thyroid States as the General Practitioner Sees Them." Participating in the discussion will be Drs Nelson M Percy on surgery, James H Hutton, endocrinology, Charles A Eliott, internal medicine and Maximilian J Hubeny, radiology. At a dinner, preceding the meeting, Dr Lahey will discuss "Thyroidectomy Technique."

Forging Narcotic Prescriptions—Don Eduardo de Ramos, following a plea of guilty to nine charges, was sentenced to one year in the House of Correction and fined \$500 and costs, November 20, for representing himself to be a licensed physi-

cian, according to the *Chicago Tribune*. De Ramos who said he was a graduate of the University of Barcelona, Spain, was seized by federal narcotic agents, November 18 who charged him with forging narcotic prescriptions for his own use. Information in the headquarters of the American Medical Association reveals that de Ramos claimed to be a graduate of McGill University, Montreal and also of the Royal Academy of Medicine, University of Valencia Spain. No record was found at either of these institutions showing the graduation of de Ramos.

INDIANA

Hospital News—Fire destroyed the Mills building at Boehne Tuberculosis Hospital, Evansville, November 25, with a loss estimated at \$85,000. The building is used for child patients, but none were in it when the fire broke out. It was the newest unit of the hospital, having been dedicated in 1929 and named for the late superintendent, Dr George E Mills. County commissioners have begun plans for rebuilding.

Society News—Dr Albert Graeme Mitchell, Cincinnati, addressed the Indianapolis Medical Society, November 21, on tonsillectomy.—The Jay County Medical Society heard Dr Robert M Moore, Indianapolis, discuss coronary occlusion at its meeting in Portland, November 3.—Dr Frank W Gregor, Indianapolis, spoke before the Gibson County Medical Society in Princeton November 13, on "Treatment of Skin Diseases Common to the General Practitioner, Including Fungus Infection."—Medical economics was discussed by Dr Everett E Padgett, Indianapolis, before the Carroll County Medical Society in Camden, November 10.—Dr Vernon M Leech, Chicago, discussed common diseases of the eye before the Porter County Medical Society in LaPorte, November 28.—At a meeting of the Fayette-Franklin County Medical Society in Connersville, November 14, Dr Frank C Walker, Indianapolis, spoke on pelvic infections.—At a meeting of the LaPorte County Medical Society in LaPorte, November 16, Dr Newell C Gilbert, Chicago discussed "Bedside Diagnosis of Cardiac Arrhythmias."—Speakers before the Cass County Medical Society in Logansport, November 17, were Drs Charles T Dutches, Galveston on "Intravenous Glucose", Harry D Tripp, Kewanee, "Local Anesthesia in Labor", and Clifford L Williams "Neurologic Changes in Pernicious Anemia."—Dr Floyd H Lashmet, Ann Arbor, addressed the Northeastern Indiana Academy of Medicine at Kendallville, November 23 on "New Concepts of Renal Function and Nephrotic Type of Edema."

IOWA

Dr Spilman Honored—Dr Smith A Spilman, past president of the Iowa State Medical Society, was guest of honor at a dinner given in Ottumwa, October 17, by the Wapello County Medical Society and the Ninth Councilor District Medical Society. Dr Charles B Taylor, Ottumwa, president, state medical society presided and, in addition to Dr Spilman, the speakers included Drs Walter L Bierring, Des Moines, President-Elect, American Medical Association, Murdock Banister, Ottumwa and Thomas U McManus, Waterloo, a former president of the state society. A gavel was presented to Dr Spilman and it was announced that a life membership in the state medical society had been conferred on him.

Tilton Fined Again—Lester J Tilton, head of the Tilton laboratories at Clinton and known to his "patients" as "Dr Tilton," was fined \$1,000 by Judge Dewey in Des Moines, November 27, for violation of the federal Food and Drugs Act. A jury had previously found him guilty in Davenport. He was given forty-two days to perfect an appeal. The fine was the maximum under the act for a first offense. \$200 on each of five counts for selling preparations falsely and fraudulently recommended for the treatment of numerous diseases. The drugs, which the government proved were falsely and fraudulently labeled, included:

Pyroligneous Compound number 1 recommended for ulcers of the stomach, sore mouth, pyorrhea, sore throat, hemorrhoids and female troubles.

Pyroligneous Compound number 2 recommended for swollen glands, varicose veins and goiter.

Healing Ointment recommended for tonsillitis, sore throat, abscesses, appendicitis, pus conditions of pleura and sore lungs.

Analyses of the products showed that the ointment was a compound of petrolatum and turpentine, and that the liquids were small amounts of pyridine, ammonia and ammonia compound. Tilton testified that the liquids were fractional distillates of peat taken from his farm. Tilton was convicted two years ago in Chicago of violation of Illinois medical practice laws. He was fined \$2,000 and sentenced to from one to five years in prison. According to the *Chicago Tribune*, the appellate court confirmed the sentence December 11.

KANSAS

Personal—Dr Calton B Grissom, Syracuse, has been appointed health officer of Hamilton County—Dr James E Wolfe, Wichita, succeeds Dr Russell E Hobbs, resigned, as city director of public welfare—The appointment of Dr Edwin C Burton, Great Bend as health officer of Barton County, succeeding the late Dr Addison Kendall, has been announced

Society News—Dr Tony G Dillon, Kansas City, discussed thrombosis of the renal veins before the Wyandotte County Medical Society, December 5—Dr La Verne B Spake, Kansas City, discussed infections of the mouth before the Wyandotte County Medical Society, November 18—At a meeting in Wellington Dr Harold Swanberg, Quincy, Ill., addressed the Tri-County Medical Society (Sumner and Cowley counties and Kay County, Okla.), November 16, on radium therapy

MARYLAND

Celebration in Honor of Dr Sudhoff—The eightieth birthday, November 26 of Dr Karl Sudhoff, professor emeritus of the history of medicine University of Leipzig was commemorated November 27, by members of the Johns Hopkins Medical History Club, in the lecture hall of the Welch Medical Library, Baltimore. Papers on the life and work of Dr Sudhoff were read by Drs Henry E Sigerist, professor of the history of medicine, Johns Hopkins University Medical School, Fielding H Garrison librarian of the Welch Medical Library and lecturer in the history of medicine, John R Oliver, associate in the history of medicine, and Ousef Temkin, associate in the history of medicine. An exhibit of the work of Dr Sudhoff was on display. Dr Sudhoff was director of the Institute of Medicine at the University of Leipzig from 1905 until his retirement in 1925 when he was succeeded by Dr Sigerist. He practiced in Germany more than thirty years, was a Prussian sanitary counselor for four years and was the first president of the German Society for the History of Medicine. He is known as a translator of Arabian and Egyptian hieroglyphics and ancient Hebrew texts. Dr Sudhoff delivered an address at the dedication of the Institute of the History of Medicine at Johns Hopkins University in 1929.

MISSISSIPPI

Society News—At a recent meeting of the Central Medical Society, the speakers were Drs E. L. Green, Carpenter, on 'Intramuscular Injection Method of Treating Pernicious Anemia with Liver Extract', Walter F. Henderson, Jackson, 'Hernia of the Stomach Through the Diaphragm Causing Hemorrhage,' and Oscar N. Arrington, Brookhaven, 'Cholecystitis'. Dr Marvin Brister Ware, Jackson, among others, addressed the society, October 3, on 'Acute Hemorrhagic Pancreatitis'. The East Mississippi Medical Society was addressed, October 19 among others by Dr Leonard Hart Meridian, on heart disorders—Speakers before the semiannual meeting of the Clarke and Six Counties Medical Society, November 8 included Dr W. L. Lickly, Memphis on 'Cancer of the Larynx,' and Col. Edward W. Smith, attorney, 'Legal Medicine'.

NEBRASKA

X-Ray Installation at Lincoln—X-ray equipment with a constant potential of 700,000 volts has been installed for treatment of cancer at the Lincoln General Hospital. An annex to the hospital was built for the new apparatus consisting of a two story room for the eight transformers, a treatment room below the room containing the 15 foot tube and a control room. Eight tons of lead was used in the lining of the treatment room. A periscope allows the physicist or physician to observe the patient constantly and microphone and loud speaker equipment makes conversation possible between them. In addition there are thirty new rooms for patients in the wing. Dedication ceremonies were held October 5 with Lauriston S. Taylor of the Bureau of Standards, Washington, D. C. as the principal speaker. Among those who attended were Drs Adolph Sachs, Omaha president Nebraska State Medical Association, Joseph Bish, Geneva president elect and Albert F. Tyler, Omaha. Dr. Ko. Coe L. Smith is the radiologist in charge.

NEW JERSEY

New Officials of State Society—The office of the Medical Society of New Jersey has been moved to 157-159 La Street, Trenton. Dr Leroy A. Wilkes is executive secretary and Dr Alfred E. Shipley, Trenton, editor of the

society's journal. Dr Henry O. Reik, Atlantic City, formerly held both these positions.

Health at Camden—Telegraphic reports to the U. S. Department of Commerce from eighty-five cities with a total population of 37 million, for the week ended December 2 indicate that the highest mortality rate (183) appeared for Camden and the rate for the group of cities as a whole was 114. The mortality rate for Camden for the corresponding week of 1932 was 154 and the rate for the group of cities, 12. The annual rate for the eighty-five cities was 109 for the forty-eight weeks of 1933 as against a rate of 11 for the corresponding period of the previous year. Caution should be used in the interpretation of weekly figures as they fluctuate widely. The fact that some cities are hospital centers for large areas or that they have large Negro populations may tend to increase the death rate.

NEW MEXICO

Personal—Dr Howe Eller, Los Lunas, has been appointed health officer of Bernalillo County to succeed Dr James R. Scott. Dr Eller's appointment will be effective, June 1, 1934, when he returns from a year's study of public health at Johns Hopkins University. Meanwhile Dr Ralph W. Mendelson, Albuquerque, will serve as acting health officer.

NEW YORK

Society News—Dr Edward M. Livingston, New York, addressed the Suffolk County Medical Society, Riverhead, October 26, on 'Abdominal Emergencies—Relation to Tenderness, Hyperalgesia and Abdominal Rigidity'.—Dr William Edward Galle, Toronto, addressed the Medical Society of Erie County, Buffalo, November 1, on 'Treatment of Fractures Involving Joints'.—Dr Ethan Flagg Butler, Elmira, addressed the Saranac Lake Medical Society, November 1, on 'Carbon Dioxide Content of Blood as an Index of Respiratory Efficiency'. Dr Stafford D. Warren, Rochester, addressed the society, November 15 on artificial fever and Dr Wardner D. Ayer, Syracuse, December 6, on intracranial hemorrhage.—Dr Murray B. Gordon, New York, addressed the Buffalo Academy of Medicine, November 22, on 'Criteria of Diagnosis of Endocrine Conditions in Infants and Children'.—Dr Frederick H. Flaherty, Syracuse, president, Medical Society of the State of New York, addressed the Broome County Medical Society and the Binghamton Academy of Medicine, Binghamton, December 5 on the work of the state society.—Dr Albert D. Kaiser, Rochester, was the guest speaker at the annual dinner meeting of the Medical Society of the County of Albany, December 12. Dr Kaiser described his experiences as physician on an expedition to Africa.

New York City

Sale of Poisonous Eyelash Dyes Prohibited—Reports of serious injury to the eyes of women and girls indulging in a new practice of dyeing eyebrows and eyelashes led the New York City health department to place a ban on the sale of all dyes containing aniline derivatives, paraphenylenediamine, paratolylenediamine and various dangerous mineral salts. No cases of eye injury have been found in New York, the department announced but a study showed that the use of dyes is increasing rapidly and the action was taken as a precautionary measure.

Afternoon Lectures at the Academy—Dr Arthur Krida, professor of orthopedic surgery, New York University and Bellevue Medical College delivered the fifth afternoon lecture of the New York Academy of Medicine, December 1, on 'Surgical Treatment of Chronic Arthritis'. Dr Lloyd F. Craver gave the sixth lecture, December 8 on 'Differential Diagnosis and Treatment of Lymphosarcoma, Hodgkins Disease and Allied Conditions'. and Dr William W. Herrick the seventh, December 15 on 'Acute Rheumatic Fever: A Review of Recent Studies and Their Relation to the Clinical Features'.

Health Services in New York—About 250 organizations that render health services are listed in a new directory of social agencies published by the Charity Organization Society. Among these are 86 general hospitals and more than 100 special hospitals which include 38 for tuberculosis, 15 for nervous and mental diseases, 9 for women and children, 9 for the chronically ill, 8 for diseases of the eye, ear, nose and throat, 7 orthopedic hospitals, 6 for contagious diseases and 5 specializing in skin diseases and cancer. There are 70 maternity services and 23 nursing services in the city. The directory shows 206 agencies for family welfare and about 200 engaged in child welfare work. More than 50 agencies provide education and

care of the physically handicapped, including 25 serving the blind, 15 the crippled, 15 the deaf and hard of hearing and 5 offering various general services to the handicapped. About 1,000 agencies are listed in the directory.

NORTH DAKOTA

Woman Physician Honored—Dr. Helena K. Wink, Jamestown, was guest of honor at a banquet given by the Stutsman County Medical Society, October 25, in honor of her completion of fifty years in the practice of medicine. Dr. William A. Gerrish paid tribute to Dr. Wink in a review of medicine in North Dakota during the past half century and Dr. Claude F. Dixon, Rochester, Minn., delivered an address on cancer of the colon. Dr. Wink is a graduate of the University of Michigan Medical School.

OHIO

Director of Surgery Appointed—Dr. Charles A. Bowers, Cleveland, has been appointed director of the division of surgery of St. Luke's Hospital, Cleveland, to succeed Dr. Carl H. Lenhart. Dr. Bowers has been acting director since Dr. Lenhart resigned last December to become director of surgery at University Hospitals. A graduate of Johns Hopkins, Dr. Bowers was on the resident surgical staff of Lakeside Hospital for seven years and has also served on the staffs of City and Charity hospitals in Cleveland. He has been president of the board of education of Shaker Heights, a suburb of Cleveland, for ten years.

PENNSYLVANIA

Society News—Dr. Richard A. Kern, Philadelphia, recently delivered a series of lectures on allergy before the Lackawanna County Medical Society, Scranton. Dr. Frederick B. Utley, Pittsburgh, addressed the Erie County Medical Society, November 7, on focal infections.

Personal—Dr. Harold A. Miller, Pittsburgh, has been appointed by the state emergency relief board as director of emergency medical relief, at the Capitol Building, Harrisburg. Dr. John C. Davis has recently been appointed superintendent of the Meadville (Pa.) City Hospital. Dr. John L. Ressler has resigned as superintendent of Lancaster County Hospital for Insane, Lancaster.

Local Physicians to Examine Conservation Corps—At the suggestion of Dr. Harold A. Miller, director of medical relief for the State Emergency Relief Board, members of the winter conservation camp corps will be examined for fitness by the local medical profession in communities where the camps are located, according to the *Pittsburgh Medical Bulletin*. In Pittsburgh, laboratory work, except urinalyses, will be done by the city department of health. A small fee will be paid for the examinations, which will be made at central examining depots on days specially arranged.

Philadelphia

Society News—Speakers at a meeting of the Philadelphia Urological Society, November 27, were Drs. Sloan G. Stewart, on "Cardiovascular Considerations in Benign Prostatic Obstruction," Herbert T. Kelly, "Medical Management of Diabetes Complicating Benign Prostatic Obstruction" and George C. Griffith, "Choice of Anesthesia in Prostatic Surgery."

Committee on Emergency Relief—Dr. George P. Muller has been appointed chairman of a medical advisory committee to the Philadelphia County Emergency Relief Board for arbitration of questions of dispute concerning payment to physicians for relief work and interpretations of the rules governing the new plan. Members are Drs. Charles A. E. Codman, Myer Solis-Cohen, William Egbert Robertson, Francis Ashley Faught, Nathan Blumberg and Isidor P. Strittmatter.

TENNESSEE

Society News—Dr. Charles C. Vinsant, Maryville, addressed the Blount County Medical Society, December 7, on "Early Diagnosis and Treatment of Carcinoma of the Cervix," and Dr. Horace Dewey Peters, Knoxville, spoke, December 14, on "Hyperthyroidism." Dr. Gilbert M. Roberts addressed the Hamilton County Medical Society, Chattanooga, December 14, on transurethral resection of the prostate. Drs. John B. Haskins, Chattanooga, and Jesse B. Naive, Knoxville, addressed the McMinn County Medical Society, November 9, on appendicitis and tuberculosis, respectively. Dr. William Litterer addressed the Nashville Academy of Medicine, November 7, on "Laboratory Diagnosis of Rocky Mountain Spotted Fever

and Endemic Typhus Fever."—Speakers before the medical society of Henry, Carroll, Weakley and Benton counties in McKenzie, November 7, were Drs. William D. Haggard, on "Carcinoma of the Colon and Rectum," Milton S. Lewis, "Treatment of Eclampsia," and Henry L. Douglass, "Interstitial Cystitis." All are from Nashville. The Washington County Medical Society held its regular meeting at the Veterans Administration Facility, Johnson City, November 9. Speakers were Drs. Walter R. Wynne and William M. Bevis, of the hospital staff, on "Roentgenologic Diagnosis of Pulmonary Tuberculosis" and "Common Neuropsychiatric Conditions," respectively. Drs. Sidney Meeker and Arthur G. Jacobs addressed the Memphis and Shelby County Medical Society, November 7, on "Therapeutic Intravenous Use of Hydrochloric Acid" and "Diet and Vitamins in Relation to Teeth," respectively.

VIRGINIA

New Editor of State Journal—Dr. Wyndham B. Blanton, Richmond, has been appointed editor of the *Virginia Medical Monthly*, official organ of the Medical Society of Virginia, to succeed Dr. Alexander G. Brown, Jr., resigned. Dr. Brown had edited the journal since 1919, when it was acquired by the society. In addition he has been chairman of the program committee of the state society and clinical professor of medicine at the Medical College of Virginia. Dr. Blanton is professor of medicine at the college and, as chairman of the state society's committee on history of medicine in Virginia, has compiled three volumes of state medical history.

PUERTO RICO

Legislature Honors Dr. Ashford—A bronze bust of Dr. Bailey K. Ashford, recently retired as a colonel of the medical corps, U. S. Army, has been completed and will be placed in the government building in San Juan. This honor was conferred on Dr. Ashford by unanimous vote of the legislature of Puerto Rico to recognize him as founder of the School of Tropical Medicine and as initiator of the first campaign against hookworm disease in America. In 1899, Dr. Ashford determined the cause of anemia of the agricultural class of Puerto Rico, later known as hookworm disease and in 1904 established the Puerto Rican Anemia Commission, which inaugurated the first drive against hookworm in America, treating 300,000 persons. Dr. Ashford is professor of tropical medicine and mycology at Columbia University, collaborating with the School of Tropical Medicine of Puerto Rico. He is a former president of the American Society of Tropical Medicine.

GENERAL

Nationwide Study of Foods Requested—A resolution requesting the federal government to cooperate with educational and medical institutions in making a nationwide study of nutritional values of foods in various sections of the country as an aid to combating dietary diseases was adopted by the Southern Medical Association at its annual meeting in Richmond in November. It was stated that studies made in isolated sections of the country are inadequate, since under certain circumstances chemical elements of foods show marked differences in value. In some localities, the resolution said, certain vegetables absorb poisonous substances which render them of doubtful value.

Oral and Plastic Surgeons Meet—Chalmers J. Lyons, D.D.S., Ann Arbor, Mich., was elected president of the American Association of Oral and Plastic Surgeons at its annual meeting in New York, November 16-18, and Dr. Ernest Fulton Risdon, Toronto, was reelected secretary. Among papers presented were the following:

Dr. John M. Wheeler, New York: Surgical Treatment of Exophthalmos in Graves Disease.
Dr. Joseph Eastman Sheehan, New York: Facial Paralysis.
Dr. William Darrach, New York: Treatment of Chronic Osteomyelitis.
Samuel R. Detweiler, Ph.D., New York: Embryonic Surgery and the Production of Anomalies.

At the annual dinner, Dr. Jerome P. Webster, New York, presented a paper on the life and works of Gaspare Tagliacozzo, "father of plastic surgery."

Index to Veterinary Literature—Through the Imperial Bureau of Animal Health, Weybridge, Surrey, England, there has just been made available the first number of a new index to the literature of veterinary medicine, *Index Veterinarius*. The editor of the *Index* is W. A. Pool, a member of the Royal College of Veterinary Surgeons and also editor of the *Veterinary Bulletin*. The *Index* is to be issued quarterly in a single alphabet. There is exceedingly full cross-indexing by countries, animals, organs and similar subheadings. Approximately one

thousand bulletins, medical and veterinary periodicals, pamphlets and reports relating to veterinary medicine are covered by the *Index*. The subscription price annually is £4.

Officers of Society of Tropical Medicine—Dr Edward B. Vedder, Washington, D. C., was chosen president-elect of the American Society of Tropical Medicine at its annual meeting in Richmond, Va., November 15-17. Dr Frederick F. Russell, New York, became president. Dr Francis W. O'Connor, New York, is vice president and Dr Henry E. Meleney, Nashville, Tenn., secretary. The next annual meeting will be in San Antonio, Texas, in November, 1934. The following honorary members were elected at the meeting: Drs William H. Welch, Baltimore; Bailey K. Ashford, San Juan, Puerto Rico; Charles Nicolle, director of Pasteur Institute, Tunis; W. A. P. Schöffner, School of Tropical Medicine, Kolonial Institut, Amsterdam, Holland; and Sir Leonard Rogers, London School of Hygiene and Tropical Medicine, London.

Government Services

Public Health Service Changes Policy on Appointment of Interns

The United States Public Health Service announces that during January, 1934, applications will be received for second year internships to begin about July 1, 1934, from physicians not over 30 years old who have graduated from class A medical schools and who will complete one year's internship at an approved hospital before next July. This is a change of policy, interns having been appointed heretofore immediately after graduation. Applications are desired only from candidates who are interested in the service as a career and who wish to take professional examinations similar to those given for appointment in the regular commissioned corps. In addition, applicants must appear before a board of the service for examination as to physical condition and general fitness. Those who pass these tests successfully will be offered appointments as interns with quarters, subsistence and laundry and \$79.74 per month. Appointments will be made according to the number of vacancies, with the understanding that opportunity will be afforded in about a year to take the regular corps examination for appointment as assistant surgeon. Attainment of the necessary passing grade in this examination will establish the candidate's eligibility (for one year) for appointment as assistant surgeon. This rank corresponds as far as pay and allowances are concerned to the rank of first lieutenant in the United States Army. Those interested should address inquiries to the Surgeon General, U. S. Public Health Service, Washington, D. C., in January to obtain more information and the necessary application blanks.

Report of Food and Drug Administration

During the last fiscal year the Food and Drug Administration collected 47,646 samples of food and drugs, according to the annual report issued November 14. The administration prosecuted 1,153 violators of the law and made 1,624 seizures. 2,777 legal actions in all. Of 22,205 samples of imported foods and drugs, 3,245 shipments were detained. The year's samples included an unusually large number of fresh fruits and vegetables examined for residues of poisonous sprays. Less than 7 per cent of interstate shipments exceed world tolerance, the report states. An important prosecution resulted in prison sentences for pedlers of poison Jamaica ginger (*The Journal*, September 9, p. 862). Others covered shipments of adulterated tomato paste, worm infested tilapia fish, dentifrices falsely and fraudulently labeled for diseases of the teeth and mouth, an inhalant falsely and fraudulently labeled as being useful in the cure of many diseases including tuberculosis and diabetes, and allegedly watered oysters. The administration made 419 seizures of worthless patent medicines and initiated 307 criminal actions. It sampled and analyzed 310 shipments of so-called antiseptics, sixty-nine legal actions being taken. During the year only eight shipments of anesthetic ether were labeled as compared with nineteen the previous year. A survey of drugs listed in the U. S. Pharmacopoeia and the National Formulary undertaken during the previous year was finished. Of 2,022 samples collected and analyzed, 352 or 12 per cent were substandard and were the subject of legal action. Thirty-four interstate and eighteen import shipments of alleged radioactive preparation were sampled during the year. Twenty of the domestic products warranted legal action and only four of the foreign shipments were allowed to enter.

Protection of Workers in Radiologic Departments

The X-Ray and Radium Protection Committee, which has been inquiring into the blood changes in workers in radiologic departments, has issued a questionnaire to hospitals, asking for details as to periodic examinations, length of service and results of treatment. At a meeting of the committee, presided over by the chairman, Sir Humphry Rolleston, the importance of blood examination as a danger signal was proclaimed. The following recommendations were made: 1. No person should be employed as an X-ray or radium worker whose blood (as tested by a complete blood count) or general health is unsatisfactory. 2. Before a person begins work or training, the normal leukocyte count should be found. If no total count reaches 6,000 per cubic millimeter and no lymphocyte count 1,200 the services of the worker should not be accepted. 3. Periodic total and differential counts should be made during the morning every six months in the case of the X-ray worker and every three months in the case of the radium worker. If a decided and sustained drop in the total leukocyte or lymphocyte count is found, the worker should cease work and be treated for an adequate period. When work is resumed, every care should be taken and the circumstances of the work be reviewed, so as to prevent any recurrence. It is not possible to lay down hard and fast rules for what may be considered pathologic changes in the blood, owing to the physiologic changes always taking place. But a leukopenia is the first change to occur in X-ray or radium workers. In order to detect this at an early stage, the following facts with regard to the content of the blood of normal persons must be taken into account. A leukocyte tide occurs twice daily, low in the morning and high in the afternoon, particularly between 3 and 4 o'clock. Superimposed on this are minor fluctuations detectable at intervals of minutes. The polymorphonuclears play the dominant part in all variations. In face of these variations, the leukocyte level of an individual can be determined only on the basis of a number of counts. Three afternoon counts should be made on the X-ray or radium worker when he begins work or training. Afternoon counts should be chosen as the afternoon rise in the number of leukocytes is less pronounced in leukopenia than normally. A mild leukopenia can thus be detected without difficulty. When the subsequent routine counts are made, a single afternoon count is sufficient, if satisfactory. If, on the other hand, it is decidedly lower than the level normal to the individual and this is confirmed by two further afternoon counts, a full investigation is essential.

Encouraging Record of Health of School Children

The annual report for 1932 of the chief medical officer of the board of education Sir George Newman shows that, with the exception of deformities not a single disease has increased since 1931. Considering the widespread economic hardships, this is encouraging. Pulmonary tuberculosis shows a marked decrease. The incidence of definite cases was 0.5 per thousand in 1925. In 1932 it was only 0.2. Suspected cases were 1.6 and 0.6 respectively. Nonpulmonary tuberculosis also fell, from 1.1 to 0.7. Unfortunately the picture is less satisfactory in the case of defects of the teeth, eyes, nose and throat. In a report on deafness Dr. Eicholz points out that 80 per cent of the cases of acquired deafness in England and Wales arise before 5 years of age, 10 per cent between the ages of 5 and 10 years and only 1 per cent after 10 years. These figures, the chief

medical officer points out, suggest that the problem of defective hearing in children of school age is educational to a much greater extent than medical. The causes of acquired deafness are predominantly meningitis, measles, scarlet fever and whooping cough. The number of children dentally inspected was 3,302,238, an increase of 7 per cent over the preceding year. The number found to require treatment was 2,285,644.

The Increasing Cancer Mortality

In opening an extension of the Liverpool Radium Institute and Hospital for Cancer and Disease of the Skin Lord Moynihan began by saying 'If the law of averages holds good, 100 people now within range of my voice will die of cancer.' He pointed out that, while the death rate of the great killing diseases had been reduced 20 per cent in the last twenty years, the death rate from cancer had increased 20 per cent. The infant death rate had been diminished by 45 per cent and the tuberculosis by 38 per cent. The greatest statistician in the world asserted that no fewer than half a million people die every year from cancer in the civilized world. Cancer was the only one of the great killing diseases in which the death rate was on the increase. The fact that more people lived to the cancer age was not a very considerable factor in the cancer mortality, nor was the greater accuracy of diagnosis responsible. If one should regard two of the organs affected with cancer in which the disease was easy to discover in the early stage one would find rather alarming facts. There had been an increase of 39 per cent in the death rate from cancer of the tongue in the last twenty years. Compared with forty years ago, the increase was 228 per cent. Excessive smoking rendered the tongue a vulnerable organ for the development of cancer. That should be a warning to the women who had adopted the male practice of smoking. The death rate from cancer of the breast had increased 28 per cent in the last twenty years.

A QUACK HAS NOT CURED ONE CANCER PATIENT

The enormous increase of cancer mortality took place despite the large number of operations performed for the disease throughout the world, with a mortality which was almost insignificant and with far more cures than ever before. Why, then, if cancer could be cured sometimes was it not cured oftener? There were many explanations. Physicians who were skeptical about the results of operation too often gave the advice "Wait and see." If the disease turned out to be cancer, there was a much greater chance of recurrence, even if the operation was performed by an expert surgeon. The incredulity of the public was another reason. Then there was the desire for irregular methods. In the whole history of medicine, not a single patient had ever been cured of cancer by a quack. Of women with local cancer of the breast 90 per cent were alive and well ten years after operation. But if the disease had long existed, 91 per cent were dead within the same period. Every case passed through a curable stage.

Ernest Edmund Maddox

The death, at the age of 73, of Ernest Edmund Maddox removes a great ophthalmologist. Born at Shipton, Oxfordshire, he was educated at Edinburgh University where he graduated in 1882 and won the Syme Surgical Fellowship in 1884 by an essay on the accommodation and convergence of the eyes. He was appointed assistant ophthalmologic surgeon and tutor on the subject in the Edinburgh Royal Infirmary. During this time he was associated with the well known ophthalmic surgeons Argyll Robertson and Berry and made a high reputation as a teacher and operator. Ill health then caused him to abandon practice, but his mental activity was so great that he published several books and articles. On recovery in

1889 he was appointed ophthalmic surgeon to the Royal Victoria Hospital, Bournemouth. At this health resort he passed the remainder of his life. He was distinguished by the originality and the clarity of his teaching. His book on the clinical use of prisms and the decentering of lenses reached five editions and became the standard work on the subject. A most original book on the ocular muscles followed and was translated into German. He dealt with disorders of the extrinsic muscles of the eye and demonstrated his points by ingenious geometric proofs. His methods of treating latent muscular defects became generally accepted. He wrote the article on refraction in Latham and English's 'System of Treatment.' He was also ingenious in the invention of instruments. The Maddox rod is used all over the world in testing for ocular imbalance. Another instrument devised by him is the chiro-scope or "eye waker" which enables the partially amblyopic eye of a squinting child to be educated by a method that excites its interest. The child is induced to make a conscious effort with its hand, while its brain is unconsciously educated to perceive the image thrown on the retina by this effort. Other devices for which the ophthalmic surgeon has to thank him are his V test for astigmatism, his axis finder and his electrical warmer. In 1900 he was awarded the Middlemore prize of the British Medical Association for his essay on heterophoria as the best contribution to ophthalmology in the previous three years. In 1921 he obtained the Doyne memorial medal of the Oxford Ophthalmological Congress. He was a deeply religious man, whose whole life was inspired by the teachings of the Bible, but he never obtruded his views. He was extraordinarily modest and was kind to his patients, whether rich or poor.

PARIS

(From Our Regular Correspondent)

Nov. 1, 1933

The French Congress of Surgery

The forty second annual session of the Association française de chirurgie the most important of the medical congresses held at Paris during the month of October, was a brilliant success. It was presided over by Professor Leriche, who, from the Faculté de médecine de Strasbourg has recently returned to the faculty at Lyons from which he came. His opening address was characterized by the presentation of many lofty ideals. He paid homage to his teacher at the University of Lyons, Professor Poncet. He pointed out that a lesion often is only the effect of a physiologic disorder that disappears spontaneously when the disorder is relieved by a slight operation such as the extirpation of the parathyroids in scleroderma. His address was well received. Three topics were studied by the congress: (1) surgery of the parathyroids, (2) immediate treatment of fractures of the base of the cranium, and (3) surgical treatment of profuse gastroduodenal hemorrhages associated with ulcer.

SURGERY OF THE PARATHYROIDS

Velti of Paris and Young of Strasbourg presented a study on 'The Surgery of the Parathyroids.' The former gave a description of the surgical anatomy and emphasized the preponderant role of the external parathyroids and the need of avoiding their artery, which is terminal and the ligation of which always entails a necrosis. He considered at length the significance of calcemia and the various methods of determining it. Calcemia is highly important in hypoparathyroidism and in hyperparathyroidism but it does not play a part in slight functional disorders. In postoperative hypoparathyroidism calcemia is only an effect and not a cause. The untoward incidents may be grave, acute or chronic. Medical treatment has little effect, and grafts are seldom successful. Mr. Young considered particularly hyperthyroidism and the

clinical symptoms that it produces. Experimentally it acts on the metabolism of calcium and of phosphorus, which are always stimulated. He pointed out the chief clinical syndromes induced by the parathyroids: Recklinghausen's disease, ankylosing arthritis (in which surgery effects an improvement in only 25 per cent of the cases), osteomalacia, Paget's disease, scleroderma and keloids. He closed with a discussion on the technique of various operative methods. In the discussion that followed, Mr Mandl of Vienna stated that one often finds hypertrophy without adenoma, in which case an operation does not give good results. Mr Snapper of Amsterdam spoke on the changed proportions of calcium and of phosphorus, and on the value of ergosterol. Mr Alessandri of Rome referred to fourteen cases in which operation was followed by bad results and two recoveries from adenoma. Mr Pautrier of Strasbourg brought out that in scleroderma and in keloids he found hypercalcaemia in two thirds of the cases. Mr P. Weil discussed the relations between ankylosing rheumatism and the parathyroids. Weissenbach, Gteller, Durupt and Rocher (Bordeaux) referred to cases of scleroderma improved by operation. Moulouguet, de Quervain (Liege), Berard (Lyons), Paolucci (Bologna), Ufreduzzi (Turin) and Albert (Liege) discussed their operative treatments.

The immediate treatment of fractures of the base of the cranium was the subject of two papers by Lenormant and Patel (Paris) and Wertheimer of Lyons, who gave a minute description of cerebral and bony traumas and of all the proposed theories, without stating any very definite conclusion, so widely divergent are the views. In general they condemned the undue use of lumbar puncture and recommended as a preferable means of diagnosis an examination of the intraspinal pressure and observation of the retinal circulation. Suboccipital puncture and posterior drainage by the Ody method sometimes give good results. Likewise preventive anti-infectious serotherapy is useful.

The papers that followed led to some confusion, as each author vaunted his own special methods. Mr Lhermitte expressed the view that vasomotor disorders play the principal role in the accidents and that the surgeon can do nothing more than apply decompression by means of trephination. Mr Henschen of Basel expressed the same view. Mr Baillyard emphasized the value of an examination of the retina. Mr Ody of Geneva pointed out that his method of posterior drainage is valuable only for the purpose of counteracting blocking. Mr Orban of Liege recommended ventricular puncture. Mr Delrez of Liege reported a series of 128 cases with 22 per cent mortality. Mr Oltramane of Geneva cited 280 cases in which intervention gave disappointing results. Mr Bacin of St Quentin handled 180 cases treating medically the simple cases and applying trephination in grave cases. Mr Termier of Grenoble has been disappointed with the results of trephination and drainage and remains true to spinal punctures deciding each case on its own merits the same as Mr Masini of Marseilles. Likewise Mr Martin of Brussels favored lumbar puncture as against trephination; likewise Mr Dziembowski of Poland. Mr Lyster of Ghent recommended intravenous injections of methuamine to prevent infection and Mr Proust of Paris advocated radiotherapy to aid in the absorption of hematomas. Mr Julliard of Geneva reported a series of 2086 cases covering a period of ten years. Of the 836 last cases 31 per cent had a fatal issue on the spot, 15 per cent were beyond the aid of surgery. Of the others 52 per cent ended in recovery and 28 per cent in invalidism. Mr Suecchal of Paris advocated lumbar puncture and Mr Arnaud of Marseilles ventricular puncture. Mr de Martel recommended manometric study of spinal pressure and emphasized the value of ventriculography.

On the surgical treatment of severe gastroduodenal hemorrhages of ulcerous origin there were two papers that of

Mr Felix Papin of Bordeaux dealt with the clinical indications. The danger from shock, the possible error in diagnosis, and the difficulty of finding the ulcer cause one to hesitate. Mr Vilmoth of Paris discussed the indications for medical and surgical treatment. Perforation is an indication for operation. For the intervention, local anesthesia is preferable. The exact nature of the intervention will be determined only after laparotomy but should be radical rather than palliative (gastrectomy and pylorotomy, gastroduodenectomy). For the last mentioned operation, which is of rather grave import, exclusion of the pylorus, associated with gastro-enterostomy, may be substituted. To summarize, treatment of these hemorrhages requires a surgeon with a clinical sense of caution and skilful in all forms of operative technique.

In the discussion, Mr Wilkie of Edinburgh took a conservative stand. An operation, he contended, is not advisable in peptic ulcer, unless the hemorrhages are repeated. Gastrectomy appears to him rarely indicated. In duodenal ulcer, ligation of the vessels and gastro-enterostomy give good results in most of the cases. The mortality is twice as high in men as in women. Mr Finsterer of Vienna advocated early operation as soon as the diagnosis of ulcer is reached. Late operations give mediocre results, but, he contends, still superior to the results of medical treatment. Mr Oliani of Trieste presented his personal statistics, which favored early and radical intervention. Mr Alessandri of Rome advised beginning always with medical treatment, with repeated small blood transfusions, with a view to operating later when the patient has become stronger. If the hemorrhage is repeated, an operation should be resorted to, following a heavy blood transfusion. Tricer and Clavel (of Lyons) reserve intervention for the cases of arterial erosion of callous ulcers, which may often be diagnosed clinically, and for hemorrhages due to stasis above a stenosis, here a derivative intervention is sufficient. Hemorrhage due merely to gastritis, with or without ulcer, requires most commonly medical treatment, or a later operation between attacks. Several surgeons presented their own statistics. Begoun of Bordeaux, Loewy of Paris, Dziembowski of Poland, Podlaha of Brno, Ferey of St Malo, Delageniere, Jr, of Lemans, Pauchet of Paris, Arnaud of St Etienne, and Santy of Lyons.

The discussion of the papers on the three official topics was followed, as usual, by a large number of individual communications on divergent subjects pertaining to surgery: surgical treatment of lung cavities, Dr Maurer, Paris; treatment of exophthalmic goiter by means of subtotal extracapsular thyroidectomy, Dr Gentil. Two of these communications in particular awakened the interest of the congress: that of Dr Calot of Berck who demonstrated that, in congenital luxations and subluxations of the hip, his treatment by early reduction and application of a plaster cast in young patients, and by the application of a special orthopedic apparatus in the case of adults gives results much superior to those secured by surgeons who apply bony grafts. He strengthened his demonstration with roentgenograms taken of persons operated on in the manner last described.

There were numerous presentations of technical films. Numerous demonstrations were given each morning in the hospitals.

The three topics selected for discussion at the congress next year were (1) surgery of the suprarenal glands, (2) treatment of acute suppurative arthritis of the knee (war wounds excepted) and (3) pathogenesis and treatment of proliferative and stenotic rectitis.

Death of Dr Roux

The death of Dr Louis Roux, director of the Institut Pasteur at the age of 83 is announced. He served as the prepar-

ator of Pasteur and was associated with him in his researches on anthrax and rabies. He discovered the antidiaphtheritic serum simultaneously with Behring, and the antitetanic serum at the same time as Vaillard. Since then he had devoted himself exclusively to the management of the Institut Pasteur. The government took charge of the funeral ceremonies and the burial.

Reforms in the Institutions of Higher Learning

The reorganization of German institutions of higher learning is now being carried out. New regulations concerning habilitation at Prussian institutions have been established. Henceforth the demonstration of scientific performances or qualifications before the faculty in question will not suffice to secure permission to lecture at a Prussian institution of higher learning. An applicant must have served several months in a field station or a work camp and must have completed a course of training in an academy for the training of instructors in higher institutions of learning, which academy is to be newly created. When these two courses have been completed satisfactorily, a candidate for habilitation in a university or other higher institution will present his credentials to the faculty of the school in question, which will act on his application in the same way as heretofore. In the reorganization of the universities and other institutions, special importance is placed in the training of the oncoming generation of academic instructors. In the new regulations, it is emphasized that the decision whether an applicant has the necessary qualifications to become an instructor in a given institution was heretofore left to the faculty of that institution and in some cases entirely to the single representative of a department since, with the growth of the faculties, the faculty as a whole could not always form a judgment concerning the applicants. The result was, one reads further, that the selection of candidates was controlled more and more by departmental points of view and that the more general considerations were necessarily forced into the background. Thus capable scholars in a given field were selected and the general qualifications were left to chance. If the universities are to undergo a real reorganization, a fundamental change in the method of selecting new instructors must be made. The new decree of the Prussian minister of public instruction, it is pointed out, has in two ways taken account of this need, for in the work camp the candidate has an opportunity to reveal his true character, in surroundings that are not academic. The testimonial issued by the work service will have great weight in determining a candidate's suitability for habilitation. The Dozentenakademie (for the training of instructors) will receive acceptable candidates from the Arbeitsdienst (work service) and will provide regular courses for candidates seeking admission to the various departments of the university. In this academy, candidates will participate in a strictly organized community life and will study courses of a general scientific character. Here, again, the candidate will have to prove his worth in fields outside his specialty. As a result of close collaboration with his fellows in the academy a candidate is expected to develop the general impulses requisite for his scientific work in his specialty. The examination of the candidate in his specialty, which follows in due course, is, according to the new regulations, only the final step in the habilitation procedure. It is emphasized that no one will be selected as instructor solely on the basis of his capacity in his scientific specialty.

The *dozenten* of Prussia (instructors in universities and higher institutions of learning) have been organized into a

society. Several different posts have been created in keeping with the duties to be performed. There is a scientific bureau, which will deal with all questions bearing on the scientific training of the oncoming generation of instructors, questions pertaining to reforms in the curriculum, and the question of the rights and privileges of Germans who have emigrated to foreign countries. There is also a bureau for work service, which is closely connected with the corresponding bureau of the German student body. Further bureaus have been created to aid in the solution of the technical problems at the various universities and higher institutions. At the several universities, a corresponding organization will be effected before the opening of the fall semester. The local directors were recently admitted to a field station. Assistants and instructors who have no fixed appointment must become members of the *dozentschaft* or society of instructors, but instructors holding definite posts and assistants in research institutes and in municipal hospitals attached to a university, may join or not, as they see fit.

The University of Giessen in Hesse has adopted somewhat different regulations. In Hesse the rector of a university may grant the *venia legendi* to a *privatdozent* if the ministerial department having jurisdiction has given its consent, at first for a period of seven years, subject to cancellation. If, before the end of the seventh year, a *privatdozent*, or instructor, has not been appointed to a professorship he automatically severs his connection with the instructional staff. This provision applies also to those instructors who have been previously appointed. Any one who is called by the government to occupy a chair is appointed as professor. The federal governor may appoint a *privatdozent* as a professor after at least five years of teaching activity. A *privatdozent* may, through the mediation of a colleague, appeal to the dean of the faculty and request that he be appointed as professor.

Reorganization of the Antituberculosis Campaign

With the transformation of the *Zentralkomitee* into the *Reichs-Tuberkulose-Ausschuss* as announced in *THE JOURNAL*, September 2 p. 791, the authoritative state shows a determination to guarantee a more uniform conduct of the antituberculosis campaign. The previous efforts to effect a consistent organization of this crusade had the administration of the new committee stated, benefited only a portion of the people (the insured and their families), whereas the constantly increasing army of persons receiving welfare aid, and the families of the uninsured middle class, received scarcely any benefit. The most important factor, however, was that the mode of combating tuberculosis was not compulsory but was dependent to a great extent on the degree of interest shown by the persons affected, and on their financial condition. Furthermore, there was too much dissipation of energy in the organizations, and the individual patient was often neglected because of uncertainty as to which organization had jurisdiction. Duplication of effort was the result. This was shown in the erection of an undue number of institutions and homes of various kinds, for the care of the tuberculous. Often legislators or judicial administrators were called on to decide purely medical questions. Now the *Reich-Tuberkulose-Ausschuss* is the tuberculosis central. The committee is appointing a director for every district throughout the reich. The directors will be phthisiologists, who will see to it that all measures against tuberculosis are carried out uniformly. The present impracticable methods in vogue in most of the tuberculosis sanatoriums must be abolished. It may be impossible to avoid closing some institutions. It may be necessary to use some institutions for other purposes, in order more fully to use the others. An attack is to be launched against lupus. A special memorial on the subject has been prepared. The objective is a rapid and complete rounding

up of all lupus patients, bringing them under suitable medical treatment—when necessary, in special institutions and institutions of regular after-care—by proper organizations, until a complete cure is effected. As an introductory measure, a complete listing of all lupus patients has been undertaken, blanks on which the names of all such patients are to be entered having been sent to all practicing physicians.

NETHERLANDS

The Antituberculosis Campaign in the Netherlands

The tuberculosis mortality rate for the Netherlands during the past thirty years has dropped from 194 per hundred thousand in 1901 to 75 per hundred thousand in 1930. The Netherlands has at present the lowest mortality rate from tuberculosis of any country. At Amsterdam the tuberculosis mortality rate has diminished greatly, being at present only one third that of Paris. These results make interesting a study of the organization of the crusade against tuberculosis. The characteristic feature of the Netherlands system is private initiative. No legislation has been passed in the Netherlands concerning the combating of tuberculosis. The state however, subsidizes and controls the organizations founded to combat tuberculosis. The annual subsidies received from the state amount to 1,300,000 florins (\$800,000, current exchange). In addition to this participation by the central government, the provinces and the communes furnish financial aid. The government control is effected through a subdepartment of the ministry of the interior, which is charged with everything that concerns the hygiene of childhood, and crusades against tuberculosis and venereal diseases.

The organizations promoting the crusade against tuberculosis comprise the Central Netherlands Association, the provincial associations and the local associations. The central association comprises about 4,000 members and supervises a vast publicity campaign throughout the country. In each of the eleven provinces there is a provincial association which coordinates the local societies. There are 800 local societies, for which the crusade against tuberculosis constitutes the exclusive form of activity.

The antituberculosis dispensaries function in association with the attending physician. The country is divided into twenty-eight districts and each district has a dispensary in approximately the center. In the larger communes there are radiologic dispensaries to the number of 109. In charge of each district is a phthisiologic specialist who gives his whole time to this service. Experience has shown that the presence of the medical specialist in each dispensary is indispensable to securing the complete confidence of the attending physicians and the patients and there is no question that this method has produced good results. No treatment is given in any of the antituberculosis dispensaries in the Netherlands. The therapeutic institutions comprise sanatoriums, hospitals and centers for ambulatory patients. There are thirty-five sanatoriums available with a total of 3,560 beds. Patients who cannot go to a sanatorium receive ambulatory treatment in so-called day camps. The country has also about a hundred hospitals each with a special department for tuberculous patients. Three types of organizations provide child prophylaxis: the sanitary colonies, the sanitary schools and the fresh air placement centers. Mention must be made also of the extensive trial of preventive vaccination with the BCG vaccine as carried out at Amsterdam which has diminished child mortality to a considerable extent.

The problem of postanatomical aid has been solved in the Netherlands as follows: There is no permanent post anatomical

aid. The establishments confine their activity to temporary aid. Here patients are subjected to a progressive occupational reeducation, under severe medical control. In addition to these colonies, there are, in most of the provinces, workshops reserved for tuberculous patients, which are usually located near large cities. Several points stand out from this study. It will be seen that a methodical spirit and a sense of coordination characterize the organization of the antituberculosis crusade in the Netherlands. Collaboration of the general practitioner in the antituberculosis crusade contributes much to the ferreting out of cases. This is based on a strict abstention from all therapeutics in the dispensary. By reason of its organization, the dispensary becomes a center of the antituberculosis crusade, and its influence extends to the whole population.

Occupational Therapy in the Treatment of Tuberculosis

At the request of the association for occupational therapy and after-care in the treatment of tuberculosis, Drs. Bronkhorst, Hefting and Van Lier presented a communication on this subject. During the acute period, rest is absolutely required, either combined with special treatment or otherwise. Once a patient has improved to an extent that one can expect no further improvement from the treatment, occupational therapy should be begun to restore the patient's strength and readapt him progressively to a normal life. The patient receives no compensation for this work, as it serves exclusively for his rehabilitation and is of a different character from work that is paid for. In many patients a satisfactory rehabilitation cannot be brought about because there is a discrepancy between the recovery to be accomplished and the condition in which the patient may find himself after treatment. The after-treatment may, however, be remedied somewhat by (1) adaptation of hygienic and social conditions to the state of the rehabilitated patient, (2) augmentation of the theoretical and practical occupational value, and (3) regular medical examination. The tuberculosis treatment is dependent on two conditions: (1) degree of restoration and (2) nature of the conditions.

Effective treatment presupposes sufficient strength on the part of the patient. In estimating the patient's strength, account must be taken of the duration factors and especially of the time when the work is to be done. Tuberculous patients who do not recover 60 per cent of normal strength cannot usually be said to have recovered and are only temporarily improved.

Marriages

IVAN MAGNUS SANDBERG, Lostant, Ill., to Miss Charlotte Drew of Iron Mountain, Mich., at Tiskilwa, October 13.

ROBERT ELMER SUMMITT, Gainesville, Fla., to Miss Willie May Lang of St. Petersburg at Palatka, October 12.

RICHARD KLATTE SCHMITT, Columbus, to Miss Margaret Gordon Laing of Iron Mountain, Mich., in October.

CHARLES G. SMITH, Red Bud, Ill., to Miss Madlen Hauff of Chicago at West Chester, Pa., October 4.

DOUGLAS HAMILTON SPRLAY, Durham, N. C., to Miss Edith Charlescraft Lucas of Charlotte, October 17.

SAMUEL BASIL SOLLEY, Coalburg, W. Va., to Miss Goldie Elizabeth Knight, August 16.

SAMUEL EDWIN HUGHES, JR., to Mrs. Willa Mae Davidson, both of Los Angeles, November 3.

RUDOLPH B. SIEGERT, Pima, Ill., to Miss Margaret Mary Twiss of Chicago, in November.

ROGER L. CREFFEL, to Miss Frances Irene Mitchell, both of Richmond, Va., October 21.

WILLIAM CHRISTOPHER SCHILLER, Galena, Ill., to Miss Ruth Enderes at Joliet, October 8.

HUBERT WOKA, to Mrs. Ethel Reed Gano, both of Denver, December 8.

Deaths

Alfred Fabian Hess * member of the Council on Pharmacy and Chemistry of the American Medical Association since 1932, died at his home in New York, December 6, of heart disease, aged 58 years. Dr Hess was born, Oct 19, 1875. He received his A B degree from Harvard University in 1897 and the M D degree from the College of Physicians and Surgeons of Columbia University in 1901. Following his graduation he studied abroad in Prague, Vienna and Berlin. He began the practice of medicine in New York, becoming professor of clinical pediatrics at the University and Bellevue Hospital Medical College. While in the practice of medicine he constantly engaged in research particularly in the field of nutrition. In this work he contributed not only of his efforts and time but also financially. His contributions especially in the field of the vitamins brought him international recognition. He received the honorary degree of doctor of science from the University of Michigan in 1930, he was awarded the Johns Scott medal and the sum of a thousand dollars for his method of producing a vitamin factor in food by the use of ultraviolet rays in 1927. In 1933 he was invited to deliver the Ingleby lecture at the University of Birmingham in England. Dr Hess was a member of the Association of American Physicians, the American Philosophical Society, the American Pediatric Society, the Society for the Advancement of Clinical Investigation and the Society for Experimental Biology and Medicine. He took intense interest in his work for the Council on Pharmacy and Chemistry, regularly attending each of its sessions and devoting much of his time to its problems. His contributions to medical literature included many papers in the field of pediatrics and experimental pathology and special monographs on scurvy and rickets. His death is a serious loss to the organizations to which he gave his services.

Miles Fuller Porter * professor of surgery in the Indiana University School of Medicine, Indianapolis, died in Fort Wayne, December 6. Dr Porter was born in Decatur, Ind. Sept 27, 1856. Following his education in the public schools, he received his M D from the Medical College of Ohio in Cincinnati in 1878 and an honorary M A degree from Franklin College in 1882. For some fifteen years after his graduation he did a general practice, devoting his attention thereafter wholly to surgery. He contributed many scientific articles to medical periodicals. Throughout his life he was especially interested in medical organization, serving as president of the Indiana State Medical Association, 1895-1896 and of the American Association of Obstetricians, Gynecologists and Abdominal Surgeons, 1912-1913. In the American Medical Association he was a member of the Board of Trustees from 1900 to 1909, the period immediately following the reorganization of the Association and one of the greatest importance for the development of the Association. He served also as a member of the House of Delegates of the American Medical Association in 1912 and from 1915 to 1918. Dr Porter was surgeon to St. Joseph's Hospital and consulting surgeon to the Indiana School for Feeble-minded Youth. He was also a member of the American Surgical Association, the Southern Surgical Association and Western Surgical Association, and a fellow of the American College of Surgeons.

Henry William Shaw * Augusta, Ga. Maryland Medical College, Baltimore, 1905, member of the state board of control for eleemosynary institutions, formerly associate professor of obstetrics, University of Georgia Medical Department, at one time member of the city, state and county boards of health, served during the World War, aged 51, died, October 27, of arterial hypertension and cerebral hemorrhage.

William Augustus Carnes, Memphis, Tenn. Tulane University of Louisiana Medical Department, New Orleans, 1896, served during the World War for many years in the U S Public Health Service on the staff of the U S Marine Hospital, aged 61, died, November 20, in the Gartly-Ramsey Hospital, of arteriosclerosis and bronchopneumonia.

Edwin Cassius Bates * Houlton, Maine. Columbia University College of Physicians and Surgeons, New York, 1908, member of the Associated Anesthetists of the United States and Canada, past president of the Aroostook County Medical Society, formerly on the staff of the Aroostook Hospital, aged 50, died, September 23.

Henry Clement Finch, Broadalbin, N Y, Albany (N Y) Medical College, 1882, member of the Medical Society of the State of New York, for many years president of the board of education, bank president and county coroner, aged 75, died November 15, of carcinoma of the prostate and diabetes mellitus.

Hiram Lionel Horsman, North Grafton, Mass., Medical School of Maine, Portland, 1899, member of the Massachusetts Medical Society, American Psychiatric Association and the New England Society of Psychiatry, assistant superintendent of the Grafton State Hospital, aged 63, died, November 13, of coronary thrombosis.

Cecil de Joline Harbordt, Dover, Del. Maryland Medical College, Baltimore, 1905, member of the Medical Society of Delaware, served during the World War, formerly on the staff of the Kent General Hospital, aged 50, died, November 6, in the Delaware Hospital, Wilmington, of hemorrhage due to esophageal varices.

Jacob Sidwell Hackney, Uniontown, Pa., Jefferson Medical College of Philadelphia, 1885, member of the Medical Society of the State of Pennsylvania, formerly secretary of the Fayette County Medical Society, on the staff of the Uniontown Hospital, aged 71, died, November 9, of myocarditis and coronary occlusion.

Frank Linden Richardson * Boston, Harvard University Medical School, Boston, 1903, member of the Associated Anesthetists of the United States and Canada, lecturer in surgery, Tufts College Medical School, anesthetist to the Boston City and Children's hospitals, aged 56, died, November 16, of heart disease.

Calvin T. Hood, Chicago, College of Physicians and Surgeons of Chicago, 1885, member of the Illinois State Medical Society, on the staffs of the Cook County, Illinois Masonic and Garfield Park hospitals, aged 71, died, November 23, at Rochester, Minn., of heart disease, following an operation for goiter.

Parker Fletcher Southwick * Sandusky, Ohio, Western Reserve University Medical Department, Cleveland, 1902, at one time county coroner, served during the World War, for merly on the staff of the Good Samaritan Hospital, aged 55, died November 20, of cerebral hemorrhage.

William Robbins White, Providence, R I, Harvard University Medical School, Boston, 1877, an Affiliate Fellow of the American Medical Association for many years on the staff of the Rhode Island Hospital, aged 84, died, November 3, of arteriosclerosis and bronchopneumonia.

Horace Gibson, Sheldon, Ill., Northwestern University Medical School, Chicago, 1892, member of the Illinois State Medical Society, for many years mayor of Sheldon and member of the school board, aged 76, died, November 15, of coronary and cerebral thrombosis.

Charles Aloysius O'Reilly * Devon, Pa., University of Pennsylvania School of Medicine, Philadelphia, 1900, member of the American Academy of Ophthalmology and Oto Laryngology, served during the World War, aged 55, died, November 1, of heart disease.

Joseph Ambrose Kerrigan * Webster Groves, Mo., University of the City of New York Medical Department, 1893, member of the Medical Society of the State of New York, aged 66, died, November 5, in the Evangelical Deaconess Hospital, of heart disease.

William James Costar, Jr * Chico, Calif., University of California Medical School, San Francisco, 1927, past president of the Butte County Medical Society, on the staff of the Enloe Hospital, aged 33, died, October 25, as the result of an automobile accident.

Emilius Morancy McKee, Lexington, Ky., Miami Medical College, Cincinnati, 1900, member of the Kentucky State Medical Association, aged 57, formerly on the staff of St. Joseph's Hospital, where he died, November 17, of carcinoma of the stomach.

Earl Rzee, Ames, Iowa, Iowa State University of Iowa College of Medicine, Iowa City, 1891, College of Physicians and Surgeons of Chicago, 1895, member of the Iowa State Medical Society, bank president, aged 65, died, October 30, of heart disease.

William Summeriff Vanneman, Tabriz, Persia, University of Pennsylvania School of Medicine, Philadelphia, 1888, an Associate Fellow of the American Medical Association, medical missionary, aged 70, died, October 30, of pneumonia.

James Mark Scoville, Warren, Ohio, Western Reserve University Medical Department, 1885, for four years county coroner, aged 74, formerly on the staff of the Warren City Hospital, where he died, November 12, of agranulocytic angina.

Adolph Ernest Voges, White Bear Lake, Minn., University of Minnesota College of Medicine and Surgery, Minneapolis, 1904, city and county health officer, deputy county coroner, aged 54, died, October 21, of heart disease.

Stephen Allen Newman, Mount Vernon, Mo., Marion-Summs College of Medicine, St. Louis, 1892 member of the Missouri State Medical Association aged 65, died, August 18, of injuries received in an automobile accident

John L. Hervey, Martins Ferry, Ohio Medical College of Ohio, Cincinnati, 1892, member of the Ohio State Medical Association aged 66, died, November 14, in the Martins Ferry Hospital, of chronic appendicitis and peritonitis

John Quincy Owsley, Nashville Tenn. University of Tennessee Medical Department, Nashville, 1894 member of the Tennessee State Medical Association aged 62, died November 20, of carcinoma of the pancreas

John Robinson Dickson, Shouchow Anhwei China University of Toronto Faculty of Medicine, Toronto Ont. Canada 1910, medical missionary, aged 49, died November 24 in Hwaiyuan of acute endocarditis

Ernest Stanley Barker, Cambridge, Mass. College of Physicians and Surgeons of Chicago School of Medicine of the University of Illinois 1899 aged 63 died suddenly November 6, of heart disease

Thomas Marshall Sloan, Newton N. C., Medical College of Virginia Richmond, 1929 aged 30 died November 12, in a hospital at Statesville, as the result of injuries received in an automobile accident

Charles Elmer Spring, Chicago Bennett College of Eclectic Medicine and Surgery, Chicago, 1893 aged 63, died November 9 in the Billings Memorial Hospital of a tumor of the prostate

Arthur J. Simpson, Chillicothe Mo. University Medical College of Kansas City, 1895, on the staff of the Chillicothe Hospital, aged 59, died, October 31, of heart disease, following pneumonia

Robert Pearmain Loring, Newton Mass., Harvard University Medical School Boston 1875 member of the Massachusetts Medical Society, aged 81 died October 28, of cerebral hemorrhage

Joseph Albert Coogan, Windsor Locks Conn., Bellevue Hospital Medical College, New York 1876 formerly member of the state legislature, aged 84, died November 24 of pneumonia

Ocran W. Roff, Newton Kan. College of Physicians and Surgeons of Chicago 1893 member of the Kansas Medical Society also a pharmacist aged 66 died, October 28 of pneumonia

James Ashby Franklin, Cameron Mo. Jefferson Medical College of Philadelphia 1886 Bellevue Hospital Medical College New York 1888 aged 71, died November 10 of heart disease

William Burgess Carman, Rochester N. Y. Hahnemann Medical College and Hospital Chicago 1884 aged 76, died November 14 of chronic bronchitis with bronchiectasis

Bernard Francis McElroy, San Francisco University of California Medical Department 1899 aged 60, died November 7, in St. Francis Hospital of cerebral hemorrhage

Henry Ost, Newark N. J. Bellevue Hospital Medical College New York 1894 member of the Medical Society of New Jersey, aged 69 died October 16 of cardiac embolism

Herman August Bohl, Clear Lake S. D. Bennett Medical College Chicago 1912 aged 49 died November 10 in a hospital at Madison of abscess of the right lung

Albert J. Foelsch, Gobles Mich. Bennett College of Eclectic Medicine and Surgery Chicago 1898 aged 57 died November 18 of a self-inflicted bullet wound

Harold Lawritz Stolpestad, St. Paul University of Minnesota College of Medicine and Surgery Minneapolis 1901 aged 54 died October 15 of heart disease

Ella Prentiss Upham, Asbury Park N. J. Woman's Medical College of Pennsylvania Philadelphia 1885 aged 82 died November 6 of cerebral hemorrhage

Christian H. Risser, Payson Ariz. St. Louis University School of Medicine 1909 aged 54 died November 4 in St. Joseph's Hospital Phoenix of pneumonia

James Oettiker, Pottsville Pa. University of Pennsylvania School of Medicine Philadelphia 1875 aged 80 died October 19 in Shreveport La. of uremia

Vincent John Thomas O'Neill, Yonkers N. Y. Medical-Chirurgical College of Philadelphia 1915 aged 45 died August 29 of tortu and myocarditis

James Ernest Browne, Howell Mich. University of Michigan Medical School Ann Arbor 1890 aged 66 died November 16 of cerebral hemorrhage

Frank Edward Shaykett, Brandon Wis. Rush Medical College Chicago, 1894 village president, aged 68 died suddenly, November 8 of heart disease

Elvin Franklin Scheidegger, Green River, Wyo. University of Nebraska College of Medicine Omaha, 1924, aged 40, died November 4, of influenza

Elmore W. Le Roy, Chicago Hahnemann Medical College of Philadelphia, 1883 aged 73, died November 26, in Gary, Ind., of cerebral hemorrhage

William Elder Wolff, Arendtsville, Pa. Medical-Chirurgical College of Philadelphia, 1897, aged 64 died, November 3, of coronary occlusion

Claude H. McMahan, St. Louis, Missouri Medical College St. Louis, 1899 aged 58, died, November 2, of injuries received in an automobile accident

Howard Augustus Gallup, San Luis Obispo Calif. Cooper Medical College, San Francisco 1911, aged 49, died October 9, of coronary occlusion

Andrew Blair Nelson, Eastbank, W. Va. University of Louisville (Ky.) School of Medicine 1907, aged 52 died September 18 of heart disease

Thomas R. Hawkins, Cameron Wis. State University of Iowa College of Medicine, Iowa City, 1888, aged 71 died November 17, of heart disease

Albert T. Getchell, Mount Pleasant, Mich. University of Michigan Medical School Ann Arbor, 1884, aged 77, died, November 15 of heart disease

Samuel Edward Caldwell, Milan Tenn., Vanderbilt University School of Medicine, Nashville, 1889, aged 71, died November 15, of pneumonia

Charles Beaver, Detroit, Eclectic Medical Institute, Cincinnati 1881, aged 72, died, November 10, of epithelioma of the tongue and endocarditis

John Henry Trent, Marshfield Ind., Long Island College Hospital, Brooklyn, 1876, Civil War veteran aged 86, died, October 19, of myocarditis

Earl Miller, Detroit, Central College of Physicians and Surgeons Indianapolis, 1898 aged 61, died, November 22 of carcinoma of the stomach

Joseph Pryse Sutton, Kitts Ky. University of Louisville School of Medicine 1910, aged 46 died suddenly, November 6 of coronary thrombosis

George Herbert Small, Bloomington Ill. Hahnemann Medical College and Hospital, Chicago, 1903, aged 57, died October 29 of uremia

Moses Schonfield, Pittsburgh Western Pennsylvania Medical College Pittsburgh, 1901 aged 53 died October 23 of coronary sclerosis

J. M. McLendon, Gould Ark. Kentucky School of Medicine Louisville 1883 mayor of Gould aged 74 died, November 20 of carcinoma

John W. Palmer, Kuappa Texas University of Tennessee Medical Department Nashville 1887 aged 78, died October 31 of tuberculosis

Eliza A. Shetter Ray, Philadelphia Woman's Medical College of Pennsylvania Philadelphia 1886 aged 71 died November 20

D. E. Burrow, Russellville Ky. Eclectic Medical Institute Cincinnati, 1898, aged 58 died November 14 of cerebral hemorrhage

Charles L. Van Doren, Urbana Ill. Bennett College of Eclectic Medicine and Surgery Chicago 1881 aged 76 died October 27

Herman B. Tihen, Andale Kan. University Medical College of Kansas City 1893 aged 64 died October 15 of leukemia

TOXICITY OF EMETINE

To the Editor—In the review on amebic dysentery in the November 18 issue of *THE JOURNAL*, in discussing the treatment, the statement is made "In the chronic cases Craig recommends continuous treatment with emetine bismuth iodide or chiniofon." It is apparent that the writer quoted from my article in Musser's "Practice of Medicine," but in that article it is definitely stated that "in chronic amebic dysentery, during the acute exacerbations the treatment should be with emetine bismuth iodide or chiniofon." It will be noted that continuous treatment with emetine bismuth iodide is not recommended but that the use of this drug is limited to treatment during the acute exacerbations of the chronic type of amebic dysentery.

I would appreciate this statement being corrected in a future issue of *THE JOURNAL*, as it has apparently caused the impression that I recommend continuous treatment with emetine which is far from the truth. In all of my writings on this subject I have warned against such continued use of this drug because of its toxic effects and have stated emphatically that it should be used only to control the symptoms of diarrhea during the acute attack of amebic dysentery and that it should never be given to exceed 1 grain a day for a period of twelve days. Usually this dosage of emetine will control the dysenteric symptoms in from five to eight days. I have also repeatedly stated that emetine is of very little value in actually curing cases of amebiasis and for this reason other drugs should be used for this purpose, emetine being relied on only to control the acute symptoms of amebic dysentery, which it does very satisfactorily.

Medicine, Tulane University of
Louisiana School of Medicine

FAVISM

To the Editor—The paper on favism by McCrae and Ullery (*THE JOURNAL*, October 28, p 1389) interested me greatly. The authors are to be congratulated for their splendid report of their case of hypersensitiveness apparently to the fava bean itself.

My interest in this bean dates back to 1924, 1925 and 1926, during which time I studied and proved clinically and immunologically that the asthma and hay fever of a patient whose symptoms occurred during the spring months were caused by the inhalation of the pollen of the fava bean. It was my feeling that "although this observation was new and original, it was withheld from our journals because it was thought that an isolated case, such as this one, would not prove interesting or important to the American allergists, especially in view of the commonly accepted theory that the pollen of cultivated plants like beans do not cause allergic symptoms." However, in 1929 I chanced to read several articles in the Italian literature describing a condition called "favismo," in which five fatal cases occurred. Realizing that an article on the fava bean would prove more valuable to physicians in southern Italy and Sicily, I submitted my paper to the *Rivista sanitaria siciliana*, which graciously published it last year. I am herewith enclosing a reprint of this paper. The paper was abstracted and published in the March, 1933, issue of the *Journal of Allergy*.

Judging from the text of the paper by Drs McCrae and Ullery, it does not occur to me that the doctors are actively engaged in the practice of allergy. It would add substantially to our knowledge of the case if the patient had had proper skin

tests made. For example, they spoke of making intradermal skin tests using 1 cc of the bean extract. It is not practical to use more than 0.01 to 0.03 cc for intradermal testing.

My purpose in this communication is not so much to establish the priority to the discovery that the pollen of this bean is the exciting cause of these severe allergic cases but more to stimulate further study and observation in so called cases of favism.

In the states of Louisiana and California and also in Canada, where the bean is cultivated to a certain extent, there must be other cases of hypersensitiveness which have not been reported because the physician never associated the pollen of the bean with the cause of the many clinical manifestations of allergy.

SALVATORE J PARLATO, M D, Buffalo

THE AMERICAN MEDICAL ASSOCIATION

To the Editor—Here is an early prophetic reference to the American Medical Association, found in "Physician and Patient, or, A Practical View of the Mutual Duties, Relations and Interests of the Medical Profession and the Community," by Worthington Hooker, M D, published in 1849. The reference is found in the chapter on "Means of Removing Quackery."

The sensible and influential in the community can render effectual aid in the overthrow of quackery by promoting the strict observance of the rules of medical intercourse. These rules are not officially understood and appreciated by the public. If they were those who have influence in society would frown down the base arts of a cunning competition instead of encouraging them as they now often do and would give no countenance to the false issues upon which empirics and dishonest physicians so much depend for their success. For a full view of this subject I refer my readers to the chapter on the Intercourse of Physicians.

A recent movement of the medical profession in this country, if I mistake not, is destined to exert a great and a permanent agency in the overthrow of empiricism. I refer to the formation of the American Medical Association in 1847. Although the meeting in Boston in May 1847 was only the second annual meeting of the Association so fully did the profession throughout the country respond to the call that the number of the delegates amounted to about four hundred and fifty. The measures which have already been entered upon and the spirit which has been manifested clearly indicate that the great object for which the Association was formed, the elevation and advancement of our common calling, will be rigorously and steadily prosecuted. The recurrence of this festival of the profession from year to year I fully believe will be marked by real advances in all the interests of medical science.

And now I ask is it too much to expect of the stable and well informed in the community that they will give their countenance to the objects at which we aim? While we are thus struggling together to elevate the standard of medical education and to rid our noble profession of the abuses which impair its honor and its usefulness we have a right to demand of the community which is to be especially benefited by these efforts a cheerful and active support. Whether this shall be given us will depend upon the men of influence in every profession and occupation in our land. It is to them that we make our appeal and we believe that it will not be made in vain.

DE KRUIF WRITES ON PNEUMOTHORAX

To the Editor—In his address as retiring president of the American College of Surgeons, Dr C Jeff Miller (*Medical Men and Their Lay Critics Surg Gynec & Obst* 54 391 [Feb] 1932) quoted Kipling's statement that "doctors always have been and always will be exposed to the contempt of the gifted amateur, the gentleman who knows by intuition every thing that it has taken them years to learn." Dr Miller further charges that "it has perhaps been easier for our traducers to gain a hearing than it has been for our defenders."

In the *Ladies Home Journal* for November, 1933, these two statements are abundantly confirmed. Paul de Kruif's article "Why Should They Go On Dying?" is a veritable storehouse of misinformation and vilification of the medical profession, as any doctor can see by securing a copy of the magazine and reading it for himself. Briefly, de Kruif had just heard of the collapse therapy of tuberculosis and, in the excitement of his discovery, thinks that because it is useful in some cases of tuberculosis it should be used in all and will save every case if used in time. He charges the medical profession with

"cowardice ignorance or neglect" (his exact words) because they neglect this life-saving procedure and names only seven places in the United States where it may be obtained—although it has been used in North Carolina since 1913 and there are at least fifteen institutions and twenty-five private practitioners in our state using it as a routine

In righteous indignation, I wrote a brief letter of protest to the *Ladies' Home Journal* correcting the most glaring of de Kruif's false statements, and offered it 'without money and without price' to its editor—but he coldly declined it

The late Mr Curtis, the founder of the company that publishes the *Ladies' Home Journal*, gave to the Jefferson Medical College the magnificent Curtis Clinic, which is perhaps the finest building of its kind in the world Its purpose is to serve humanity, and it is manned by the same medical profession that is so often vilified by such 'gifted amateurs' as de Kruif in the columns of the *Ladies' Home Journal* I wonder if the policy of the present editor of that magazine would be approved by his dead benefactor

WINGATE M JOHNSON M D, Winston-Salem, N C

VOMITING AND SPINAL ANESTHESIA

To the Editor —At the Shamokin State Hospital we have been using spinal anesthesia for the past four years (procaine hydrochloride) we consider it the ideal method obstetrics included below the diaphragm We have given 2,000 spinal anesthetics without any fatality, but vomiting occurs almost instantly, particularly in appendectomies when either a hemostat or a ligature is put on the meso-appendix However, we have changed our technic and before we put either a hemostat or a ligature on the meso-appendix we block the nerves in the meso-appendix with 0.5 per cent procaine hydrochloride and find that vomiting does not occur This, I believe, is due to the following

1 The autonomic nervous system of Langley, formed by Gaskell's nerves from the anterior horns of the spinal cord to the great sympathetic ganglions with the vagus and the pelvic nerve, forms the great thoracic and abdominal nerve plexuses and gives the appendix its nerve supply We have learned only recently that these nerve fibers are also nerves of sensation

2 Since the appendix is the only organ in the abdomen having such a well developed nervous system, irritation of this organ is considered a definite indication of chronic appendicitis (Deaver, J B Appendicitis in the *Cyclopedia of Medicine*, p 740)

The nerves of the meso appendix have no name Therefore I suggest that they be called Deavers (J B) nerves

GEORGE W REESE M D Shamokin, Pa
Surgeon in Chief and Superintendent
Shamokin State Hospital

SPINAL ANESTHESIA IN HYPERTENSION

To the Editor —Dr Albert S Hyman (*THE JOURNAL* October 25 p 1410) presents a preliminary statement on the therapeutic use of spinal anesthesia for emergency relief in certain type of hypertension He says that the depressor effect obtained by spinal anesthesia might be of value when a sudden dropping of the systolic pressure is to be desired and cites a case in which emergency in imminent cerebral hemorrhage was forestalled by such treatment He concludes that in cases of extreme hypertension exhibiting prodromal signs of coming apoplexy and with relative grades of tension spinal anesthesia may be life saving

On the other hand, Dr Stanley Cobb (*The Cerebral Circulation* XXV Remarks on Clinical Physiology *Ann Int Med* 7 299 [Sept] 1933) refers to an article which presents "a strong case for the theory that lowering blood pressure in patients with hypertension and arteriosclerosis may bring on attacks of hemiplegia and aphasia" (Fleming, H W, and Naffziger C H Physiology and Treatment of Transient Hemiplegia, *THE JOURNAL*, Oct 29, 1927, p 1484) Cobb adds

I have seen several cases where such accidents have occurred after putting arteriosclerotic patients to bed and allowing a systolic pressure to fall from around 220 to about 160 reducing the blood supply to an already poorly oxygenated brain Moreover pressure on the carotid sinus causes a sudden fall in blood pressure in some people and I have seen arteriosclerotic patients in whom such a fall brought on sudden syncope with convulsive movements

It would seem, because of these diametrically opposed views, that the advisability of lowering the blood pressure in the manner advocated by Dr Hyman is still considerably *sub judice*

LOUIS J BRAGMAN, M D, Syracuse, N Y

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be noticed Every letter must contain the writer's name and address but these will be omitted, on request

DURATION OF GESTATION

To the Editor —I recently had occasion to look up the minimal and maximal length of the human gestation period In De Lee's *Obstetrics* the observation is made that Dr Reichert of Germany has a theory stating that gestation may be complete in 252 days Is this considered authentic? Please omit name M D, Pennsylvania.

ANSWER—"By the normal end of pregnancy is meant the time at which a normally developed fetus is ordinarily expelled during the process of labor" (Zangemeister) This time, reckoned from the first day of the last menstruation is accepted as 280 days, calculated from the day of conception, it is 273 days The exact duration of gestation, that is, from the time the spermatozoon and ovum unite until labor sets in, is not definitely known However, it is assumed that fertilization takes place on an average about 154 days after the beginning of the last menstrual period Hence the average duration of pregnancy is 280 less 154 or 264.6 days In spite of this daily experience shows that mature babies are born some time before and after this average number of days In a series of 187 carefully controlled pregnancies that followed the return of German husbands on furlough during the World War, Nürnberg found that mature children were born between 266 and 282 days after conception in 68.26 per cent between 258 and 290 days in 95.46 per cent and between 250 and 298 days in 99.74 per cent Since in only 0.26 per cent of the cases were mature children born before the two hundred and fiftieth day or after the two hundred and ninety-eighth day, a pregnancy may be considered abnormally short if it lasts less than 250 days and abnormally long if it persists more than 298 days In Germany however, the law defines the duration of pregnancy as the period extending from the one hundred and eighty-first to the three hundred and second day before the birth of the child However the minimum figure in this law namely, 181 days after conception, indicates only the period of viability and not the maturity of a child The French law recognizes the legitimacy of a child born 180 days after marriage and 300 days after the death of the husband (De Lee)

It is assumed that the inquirer would like to know whether a mature child can be born after 252 days of pregnancy The statement gestation may be complete refers to a period of time whereas maturity deals with a state of development It is possible for a child to be born after 252 days and show all or most of the signs of children that are normally born at the end of 280 days According to Haberdar children may be born 238 days after conception and show all the signs of maturity On the other hand children born after the usual 280 days of gestation may not be entirely mature The best examples of this are the cases of twin pregnancies in which one child is mature and the other is much shorter in length weighs considerably less and has definite characteristics of immaturity

DIFFERENTIATION OF EDEMA FLUIDS

To the Editor—How may the edema fluids in cardiac nephritic and nephrotic patients be differentiated by their protein content? Please omit name

M D Massachusetts

ANSWER—A comparison of the results obtained in the chemical analysis of different effusions shows that they vary according to location and according to the disease in which they are produced

The proportion of protein in edematous fluids in different localities varies in decreasing order as follows (1) pleura, (2) peritoneum, (3) cerebrospinal, and (4) subcutaneous. Apparently there is a variation in the capillary permeability in these different parts of the body the pleural vessels being most permeable to protein and the subcutaneous vessels least permeable of the four

In general noninflammatory edemas (transudates) contain much less protein than do the inflammatory exudates. Non-inflammatory subcutaneous effusions have usually a protein content of from 0.1 to 0.2 Gm for each hundred cubic centimeters. There is more globulin in nephritic than in cardiac dropsy

Epstein found that the subcutaneous fluids are totally different in their composition from the abdominal or pleural fluids. The cutaneous effusions are characterized by a very low protein content and a small amount of incoagulable nitrogen. Of the protein present in these fluids the globulin constitutes the greater proportion. In the mixed cardio-nephritic fluids the ratio of globulin to albumin is lower than in normal blood serum, but when compared with the blood serums of cardio-nephritic cases there appears to be a certain parallelism

The effusions in serous cavities have a higher protein content than the subcutaneous. The highest values are found in the pleural fluids, in which the protein content is almost the same as that in normal blood serum. The incoagulable nitrogen in these fluids is low. The abdominal fluids are in general less rich in protein than the pleural effusions. Those of cardiac origin give the highest protein values. In fluid of nephritic origin the protein content is usually low, about 0.1, the borderline between transudate and exudate in protein content. Cases of true uncomplicated nephrosis are rare. The effusion in nephrosis is usually extremely low in specific gravity and protein content. The blood proteins are greatly reduced in nephrosis. This reduction is due chiefly to loss of albumin so that the globulin is relatively increased. In lipid nephrosis the total blood protein may be as low as 3.9 per cent, of which albumin is 0.5 per cent and globulin 3.4 per cent

TREATMENT OF BURNS

To the Editor—About February 18 I saw a patient suffering from burns of both legs extending up to the knees received while stepping in cement. The burns varied from the second to the third degree. The process of healing was slow and unsatisfactory. Trinitrophenol solution, tannic acid solution, trinitrophenol ointment and balsam of peru were all tried to aid the process of healing. At times each seemed to be of benefit and then again seemed to be without benefit. The areas healed over with a thin pinkish skin with a small amount of keloid formation along the edges. This new skin remained soft, pink and tender for some few weeks and did not respond to treatment. Infra-red treatments were instituted and the skin soon assumed a normal appearance. With sudden changes of weather the patient experiences pains in the legs and a discoloration of the burned areas. In walking long distances or exercising the legs the patient complains of a pulling sensation within the muscles of the leg. This is an industrial case. I would appreciate any information that you can send me that will help me to determine the amount of disability or any suggestions that may be of benefit to the patient and also what the patient may expect in the future as a result of these concrete burns. Will the leg tendons atrophy or will they remain as is? If this is published in THE JOURNAL please omit name

M D, Oklahoma

ANSWER—From the description given it is assumed that skin grafting was not necessary and that there is no interference of motion at the knee or the ankle. This would indicate that the deeper layers of the skin and the underlying tissues were not destroyed. It is probable that scar tissue formation will not grow worse, and there is little likelihood of further limitation of muscular activity as a result. The circulatory disturbance described may be improved by systematic exercises such as Buerger's exercises, or by the wearing of an elastic bandage. It is stated that the skin is of normal appearance, so it is assumed that excessive keloid formation is not present

Determination of disability depends on objective observations and a determination of the subjective elements in which the various factors, such as the patient's personality, must be considered. For the purpose of financial settlement, disability following injuries to the leg are based on disability at the knee joint. In some states, total disability at the knee such as that

following amputation, is established at 42.5 per cent of complete permanent disability. It might be established, for instance, that this individual is suffering from a 5 to 10 per cent disability at each knee

ARTERIOSCLEROSIS IN DIABETES

To the Editor—My mother has had diabetes for eight years and at present is receiving insulin daily. For the past few months she has been having excruciating pain in the lower part of both lower extremities. She is unable to walk a street block without great discomfort. Can you suggest any treatment, physical therapy or other? Would infra-red rays help any? Any information you care to send will be greatly appreciated. Please omit name

M D New York

ANSWER—From the description, the patient is apparently suffering from a restricted blood supply through the lower limbs caused by the rapidly advancing arteriosclerosis typical of diabetes. There may also be an element of vasospasm complicating the picture

The treatment for this condition is similar to that for Buerger's disease except that it is somewhat more conservative. Buerger's exercises for one hour twice daily followed by half an hour of contrast baths would probably be of benefit. Diathermy to both extremities may also help. This should be done with a plate under the anterior part of the foot and a cuff around the calf muscles. It may be applied to the two extremities at once for about one hour daily

If further treatment is required, intravenous therapy may be tried. If vasospasm is present typhoid vaccine is worth trying. One should begin with 24 million organisms intravenously once a week. If no vasospasm is present, one may use from 200 to 300 cc of hypertonic saline solution (5 per cent) intravenously every second day

It is not likely that infra-red ray therapy would be of any value

An article by Samuel Perlow entitled "Diagnosis and Treatment of Thrombo-Angitis Obliterans" in the July issue of *Annals of Surgery* contains an excellent exposition of this subject and a useful bibliography

SMALLPOX VACCINATION

To the Editor—My associates and I have had a good many vaccinations to do here lately and my attention has been called frequently to reports that vaccination is being done by hypodermic injection. On inquiry from one of my medical friends I learn that he has used this method for a number of years. He dilutes the vaccine contained in a tube with 1 cc of sterile water and injects part or the whole of it hypodermically. Kindly advise me as to the advantages and disadvantages of this method. I note that it is not advised in the literature of the manufacturers with whose products I am familiar. Please omit name

M D, Colorado

ANSWER—The hypodermic method of vaccination is regarded as objectionable since satisfactory results are obtained from the method in which the virus is implanted in the skin without resort to subcutaneous injection, and it is believed that it is undesirable to inject hypodermically material which may be infected with organisms other than that of the vaccine

This method has the disadvantage of not leaving a scar as evidence of a successful take

We know of no advantage of such a method as is described, in which the vaccine is diluted with 1 cc of sterilized water and injected hypodermically

The multiple pressure method by which the vaccine is introduced subepithelially by means of a sharp pointed needle is regarded as perhaps the most satisfactory method available

DYNAMITE HEAD OR GLYCERYL TRINITRATE (NITROGLYCERIN) POISONING

To the Editor—Patients handling dynamite in the bureau of mines frequently claim so-called headache. This is evidently due to the nitro-glycerin. Please let me know if you have any suggestion of treatment as to the causes of these conditions

MILTON MERMELSTEIN, M D McKeesport Pa

ANSWER—This well known condition is familiarly called "dynamite head." These headaches are real and at times severe. Associated with the headache there may be rapid heart beat and flushing of the face, now and then temporary blindness occurs. Gastric disturbances are frequent

Certain mine explosives, such as nitro starch, are said to cause no disturbances of this character

Apparently a tolerance for glyceryl trinitrate (nitroglycerin) is developed in some exposed workers, so long as they are continually, or frequently, in contact with it and so long as exposure is not excessive. After weekends, vacations or other absences from the point of exposure, the headaches are prone to recur

The imbibing of alcohol increases the probability of the development of "dynamite head." Likewise, alcohol increases the severity of the attack once it is inaugurated.

In order to preserve their "tolerance," some dynamite workers carry about their persons minute fragments of this substance. Children and others in the homes of dynamite workers occasionally develop headache and other manifestations, as the result of the action of dynamite particles accidentally or purposely placed in the clothing of these workers.

The analgesics commonly used to relieve the pain of headache are ordinarily without helpful influence in this abnormal state. This condition is well discussed in Dr. Hamilton's book, *Industrial Poisons in the United States*, New York: the Macmillan Company, 1929, which contains a brief summary of the literature on this topic.

ALLERGIC TESTS IN PATIENT WITH ARRESTED TUBERCULOSIS

To the Editor—In an arrested case of tuberculosis is it safe to give the patient the skin tests for allergy? I say arrested advisedly, because the condition probably is still active. The patient's temperature is now normal but she fails to gain in weight is coughing and has not gained in strength. Within the last two months she apparently has developed asthma at least so the sounds in the chest appear. The chest will be perfectly quiet and without a word of warning an apparent asthmatic attack comes on. In an hour or so it will subside but as usual in all such cases returns. The patient is anxious to have the tests but I was fearful of going ahead with them because I have not had such a case presented before. Please omit name and address. M D, Illinois

ANSWER—Not only are skin tests for the asthma permissible but they are strongly advisable, because they may disclose information that will help the asthmatic condition and prevent a flaring up of the tuberculosis. There is no danger in doing skin tests on tuberculous individuals, however, scratch (cutaneous) tests are advised, at least at first, intracutaneous tests may then be carried out safely if the cutaneous tests are negative.

The combination of bronchial asthma with pulmonary tuberculosis is infrequent and brings up the thought that either the asthmatic symptoms in the patient may be due to a fibroid tuberculosis or bronchial asthma is the sole condition present, i. e., that the symptoms deemed tuberculous might have been from allergic bronchial asthma. History, examination, sputum search and roentgen examination of the chest should suffice to differentiate. If epinephrine hypodermically gives relief, bronchial asthma is strongly suggested.

KEROSENE POISONING

To the Editor—I am trying to get some information regarding kerosene poisoning. In a local hospital during the past five years there have been seventeen admissions of young children who drank kerosene. There were three deaths and several of the children were acutely ill with high temperature. Can you send me at your earliest convenience some information regarding kerosene poisoning or mail me references so I can look up the literature on this subject as I have been unable to find any so far.

C C McLEAN, M D Birmingham Ala

ANSWER—Much of the literature pertinent to kerosene poisoning appears under such heads as "gasoline poisoning" and "petroleum naphtha poisoning." The three substances implied may not act identically but at least they do act similarly. Four types of damage are known:

(a) Dermatitis which in part is the result of direct irritation, in part the result of the defatting action of these hydrocarbons, and in part the result of sensitization.

(b) Acute poisoning from the inhalation of vapors which condition is characterized by cerebral disturbances, frequently termed naphtha jags. Persons affected behave much like those mildly intoxicated by ethyl alcohol. Excitement is the predominant manifestation. Also in this state there may be disturbances of the digestive tract with nausea vomiting and diarrhea. Low grade inflammation of the respiratory tract is well known.

(c) An ill defined chrome state is believed to exist. This form of damage resembles multiple sclerosis plus evidences of damage to the liver which may result in icterus.

(d) The inhibition of any of these substances may lead to prompt severe injury with characteristic features: surging tingling impairment of various centers of the central nervous system plus profound shock.

The following sources may be consulted for additional information:

Henderson and Hayward, *Noxious Gases*, 1927.
Lee, in *Haime and Weber, Legal Medicine and Toxicology*, 1923.
U. S. Public Health Service, *Industrial Hygiene Division*, Washington, D. C.

OPPENHEIM'S ACOUSTIC EPILEPSY

To the Editor—Can you give any information as to the condition known as Oppenheim's acoustic epilepsy? M D Conn

ANSWER—Oppenheim's acoustic epilepsy is described by Hermann Oppenheim in an article entitled *Kenntnis der Epilepsie, ihrer Randgebiete* (*Ztschr f d ges Neurol u Psychiat Orig* 33 352, 1918). There is also the following note in Alexander and Marburg's *Handbuch der Neurologie des Ohres*, Vienna, Urban & Schwarzenberg, 1928, vol II, part 1, p 554.

"2 Labyrinth Symptoms and Epilepsy. Hemispheric and epilepsy may exist together or the manifestations may be so closely allied that they present unusual difficulties in diagnosis. However, except for this combination, the distinction between these two diseases will not be difficult (Oppenheim). There is, therefore, a definite basis for associating epilepsy with vascular disturbances without considering epilepsy as a vascular disease."

In this paragraph reference is made to Oppenheim's *System of Neurology*. However, a study of this system fails to reveal anything more than a mention of the acoustic aura, a differential diagnosis between the aura and Meniere's syndrome and hemispheric.

CARBOHYDRATE IN INFANT FEEDING

To the Editor—What is the latest teaching as to the age when carbohydrate should be omitted from a child's milk and he be given just plain milk holed? What can one do when the child, accustomed to the sweetening of the milk by the carbohydrate, refuses plain milk? Kindly omit name. M D, Vicksburg, Miss

ANSWER—Carbohydrate may be retained in the milk mixture until the child is from 12 to 14 months of age. The carbohydrate as used in infant feeding is a valuable addition to the diet, tends to regulate the bowels, and avoids what may be the present-day tendency to overfeed with cow's milk for too long a period.

THE MILK AND MOLASSES ENEMA

To the Editor—In *Tonics and Sedatives* in the issue of October 21 J H McMI refers to an item of September 16 by Dr Boggess calling attention to the use of the milk and molasses enema. At first I was at a loss to see the point of the joke in this comment as I could not see the highly descriptive simile but at length it dawned on me what J H McMI was driving at that gave him such a hearty laugh, so let's carry the fun a little further.

Now I want to defend Dr Boggess not only in his use of the milk and molasses enema but also in his English. When one sets himself up as a critic in the use of English as does J H McMI he should set a good example in English himself. He calls this reference a simile. I am unable to see such a figure of speech. A simile is a comparison of dissimilar objects or things by the use of like or as. For instance we would say Washington stood as a mighty oak in the political storms of his day. Dr Boggess employs another legitimate rhetorical figure of speech known as metonymy in which one word does duty for another. For example we say that a man keeps a good table instead of a man keeps good food on his table. Now it is perfectly legitimate to say that Dr Senn brought back the efficacy of a milk and molasses enema. This is a metonymy in which the word "efficacy" does duty for the term "report of efficacy." The English language is full of such expressions and it is considered good usage.

Possibly the most benefit that may be derived from this friendly discussion is to call especial attention to the usefulness of this enema in cases of paralytic ileus or similar conditions in which other drugs and methods are found futile. I have seen gratifying results on various occasions when all other helpful remedies such as drugs high soap suds enemas and double strength solution of pituitary have failed. In a recent case of hemiplegia in which I was associated all efforts to secure a bowel movement for eleven days following the stroke were unsuccessful. On the twelfth day the milk and molasses enema was employed resulting in immediate evacuation. Therefore it will be clearly understood why the recent discussions of August 19 September 16 and October 21 attracted my attention.

HUGH MILLER, M D Kansas City Mo

ALLERGY AND FEVER OF UNKNOWN ORIGIN

To the Editor—The answer to the question on Fever of Unknown Origin in Childhood in THE JOURNAL of October 21 page 1336 fails to consider the possibility of food allergy. In fact this etiology is rarely if ever mentioned in any article on idiopathic fever. Various students of food allergy have emphasized the necessity of remembering that food sensitizations may be responsible for intermittent or prolonged elevation of temperature both in young and in adult life when other recognized causes of fever have been excluded or therapy based on such cause has failed to relieve the fever. The references and my personal experiences have been recorded in my book on Food Allergy (Philadelphia Lea & Febiger 1931) and since then further clinical confirmations have multiplied in regard to this cause. The patient's personal and family history may or may not be positive for allergy and evidence of food dislike or disagreements may or may not be present. Elimination diets, modified by the skin reactions and histories of food dislikes or dislikes, should be tried as a diagnostic procedure.

Rhode Island October Report

Dr Lester A Round, director, Public Health Commission, reports the written and practical examination held in Providence, Oct 5 6, 1933. The examination covered 7 subjects and included 70 questions. An average of 80 per cent was required to pass. Fourteen candidates were examined, all of whom passed. Three physicians were licensed by endorsement. The following colleges were represented:

College	PASSED	Year Grad	Per Cent
Yale University School of Medicine	(1931)	80 1

Book Notices

Maternal Mortality and Morbidity. A Study of Their Problems. By J M Munro Kerr MD FRFPs FCOG Regius Professor of Midwifery University of Glasgow. Cloth Price \$8.25. 1p 387 with illustrations. Baltimore: William Wood & Company 1933.

Seldom does one find a book that is so full of useful information. This fact also makes the book difficult to describe. Unlike monographs on the subject, it contains a mass of statistics gathered in Great Britain and other countries, together with a great deal of general information on the subject of maternal mortality and morbidity, with a wise interpretation of both as they relate to conditions in actual practice and to the agencies committed to their improvement. It is most convenient to have all this knowledge put together in one handy volume with a well worked out table of contents and an excellent index. After a bird's eye view of the situation in Britain by the author, there is a general review of the conditions affecting mortality by Dr P L McKinley. The statistics of the maternal death rate are presented and the bearing that infections, operative procedures and abortion have on it is clearly presented. An intriguing chapter on maternal morbidity and subsequent disablement, by Donald MacIntyre, contains stimulating facts. The prevention of maternal mortality and morbidity and the various obstetric services, their design organization and staffing, are fully treated. Nowhere will the American student find a more comprehensive review of home or 'domiliary' obstetrics. After reading these chapters he will be rudely awakened and impressed, the results of home obstetrics are so good. Of most interest to Americans will be the attitude toward the midwife. Whereas in America we are trying to get rid of this profession, in Britain the midwife looms large in all the discussions, indeed, there is a most pronounced reactionary trend toward her employment. A full description cannot be given here, but the reader can gain an idea of the midwife's status in Britain from the statement that "no one can give the medical student better training in normal labor than the experienced midwife." Excellent chapters are devoted to a transport obstetric service and to the education of medical students in obstetrics and gynecology, in which a combination of the two disciplines is recommended. The ideal maternity hospital is described and architectural plans are submitted. One sees from these that the British still cling to the old notion of a delivery room as a somewhat improved bed chamber, while the operating amphitheater is regally furnished with surgical appurtenances. What will strike the reader with great astonishment is the demand that a maternity hospital should consist of "three separate blocks, separated by wide air passages, which is preferable to isolation in flats." The author demands "a clean block" a suspect block" and "a septic block unless provision for septic cases is made elsewhere." Thus this British authority is more meticulous than the most rabid American isolationist. Valuable instruction is given for the formation of a national maternity service and the book ends with an appendix which gives consideration to the topics of the toxemias of pregnancy and the relations of general medical practice to the medical curriculum. The results of the Queen's Institute of District Nursing are presented and they are most gratifying. National health insurance and maternity has not yet received the attention in this country that it has in Britain. This book demands a place on the reading table of every obstetrician and public health officer.

Some important and interesting pages which will testify to the
 influence of the book in dealing with researches from all quarters and
 give to American readers some indication of the esteem in which the
 work of their countrymen may be held as follows: Parrot's record
 of the action is recorded but also its critical reflection by
 A. L. Herber and J. A. Carlson. It is also in California
 as shown by Leverett. Concerning the rare in the
 collection of which with color, parrot and the
 bird is also in the collection of the
 and the all the and awaken a desire in man for
 which is in this view of the advert

In the determination of salt and ionic actions, an interesting suggestion is made regarding the comparative actions of the chlorine, bromine and iodine ions. Chlorine is not oxidized but hydrochloric and hydriodic acids (to a slight extent) are therefore the latter have a stronger oxidizing

actions and it is not correct to speak of anionic or ionic actions of iodine. For if there were merely ionic actions of these halogens iodide and bromide should act like the indifferent chloride which is not the case. It is considered that carbon dioxide of the body may provide high enough acidity to permit formation of hydroiodic acid. The newer concepts of chemical and dynamic cycles in muscular work and the peculiar iodoacetic action of Lundsgaard are reviewed. In cyanide poisoning sodium tetrathionate is a more powerful antidote than sodium thiosulphate. There is no mention of methylene blue and sodium nitrite which are now known to be superior. Treatment of this poisoning requires attention to two principles first mechanical and second chemical. For resuscitation mechanical respiration is to be kept up until the poison is detoxicated for detoxication intravenous injection of thiosulphate intramuscular injection of detoxin (a sulphur splitting albuminate) or intravenous injection of dextrose or oxantin (hydroxyacetone) according to the recent work of Forst.

Surprising doubtful or objectionable to most pharmacologists at least in this country will be the following statements in the book. Listed with oxidizing antiseptics is potassium chlorate which is stated to give off oxygen slowly in the body the detoxicating action of strontium thioacetate is superior to sodium thiosulphate action of salicylates is generally held to be etiotropic in rheumatic fever tribromethanol is an intravenous anesthetic for short operations mention of valerian and a number of commercial esters of valeric acid as hypnotics veramon is a chemical union of barbitol and amidopyrine which can act as such in the body mention of no less than twelve coronary vasodilators for use in angina pectoris the biggest surprise being cast extract by mouth and others almost as surprising being adenylic acid kullikrin and related tissue products hypertonic sugar solution and digitalis glucosides but yohimbine and barbitals are perhaps more rational papaverine intravenously for migraine synephrine in asthma hay fever and hypotonus carbazole (metrazole) as an inhibitor of intestinal colic bronchial asthma and as an expectorant acetylsalicylic acid is not exactly the same thing as aspirin as to melting point and composition according to commercial tests for which authority is cited rather extensive mention of trade marked products in the text though generally not without giving the chemical composition. Antisyphilitic remedies are discussed too briefly in view of their therapeutic importance. For instance mercury gets two pages, and bismuth only nine sentences not entirely acceptable with mere citation of papers by Masson and von Oettingen. The reason is that bismuth is not popular in Germany and Austria.

However, the matter which might be questioned, or objected to, in this book is comparatively small in amount and minor. Any weaknesses are greatly outweighed by many excellent features and by the active interest and preeminence in pharmacology of its authors, which gives it the weight of authority. This book is truly representative international in scope, impersonal, and eminently fair to all those who profess and are identified with pharmacology. It is exceedingly stimulating and leaves a favorable impression of the value and importance of pharmacology, which brings to mind some comments on this subject. Once a prominent pharmacologist was asked by a biochemist in this country "What is to become of pharmacology?" and was told by a prominent medical dean "There is hardly any such thing as pharmacology it is only biochemistry and therapeutics and we shall live the subject taught by a young man on patients in the wards." Some physiologists have said that pharmacology is only a branch of physiology and not only regret but even defy its separation. A prescription for these skeptics and pessimists is a tolerable familiarity with Meyer and Pick. Here they will find the really active and productive pharmacologic talent of this country, well recognized for its contributions to and achievements in one of the most progressive of the world's medical sciences today. A desk copy of this book is indispensable to every pharmacologist and researcher in medicine, and no physician, physiologist, biochemist or medical student should regard his library complete without it. It is to be hoped that Prof V E Henderson will again render this edition into English, for Meyer-Pick is really a great work, which should not escape those who cannot read it in the original.

The Occipito Posterior Position Its Mechanism and Treatment with a New Conception of the Role of the Pelvic Floor. By Roland Beard M.C. M.B. B.S. Gynecologist Adelaide Hospital Paper Price 3/6 Pp 36 with 4 illustrations Adelaide F W Preece & Sons 1933

This interesting monograph presents a somewhat new view on the mechanism and treatment of this condition based on an analysis of more than 3,000 cases from the Queen's Home in Adelaide, together with the author's study of the pelvic floor. His concept of the role of the pelvic floor in the mechanism of the occipitoposterior position is based on the fact that he divides the pelvic floor into two functional groups (1) projection group, iliooccygeus and ischiooccygeus, and (2) rotation group, the pubococcygeus of either side. He formulates a new law "With the lie longitudinal that portion of the presenting part which is related to the anterior segment the

pubococcygeal portion of the pelvic floor, rotates to the symphysis." He divides posterior positions into two groups the true occiput posterior, with the occiput at the sacro-iliac joint and the intermediate occiput position, with the occiput anterior to the sacro-iliac joint. He believes that these positions can be differentiated clinically and that, while descent of the head has significance, flexion plays no part. Failure to rotate is due to the pelvic floor function. He is further convinced that anterior rotation through three eighths of the circle is rare.

Medicolegal

Medical Practice Acts Notice and Opportunity to Be Heard Before Revocation of License, Moral Turpitude Defined.—Tullidge was a licentiate of the state board of medical examiners of Florida. It was charged that he violated his oath when he applied for a license to practice medicine, in that he swore that he had never been convicted of a crime involving moral turpitude. He had been convicted by a court martial, it was alleged, of "scandalous conduct tending to the destruction of good morals," preferred against him when he was an assistant surgeon in the United States naval reserve force. The board fixed a time and place for a hearing on the charges. Without notice to Tullidge and without affording him an opportunity to be heard in his own defense, the board proceeded. It had before it a transcript of the evidence against Tullidge at the time of his trial by court martial, the finding of the judge advocate, and the sentence of the court martial, together with certain testimony having no relation to the present charges. Notwithstanding a request by counsel for a continuance, it having been shown that he was out of the state, that his address was unknown, and that he had never been personally served with a copy of the charges against him, the board peremptorily struck Tullidge's name from the roll of those licensed to practice medicine. Thereafter Tullidge instituted an original proceeding in the Supreme Court of Florida for a writ of mandamus to compel the board to restore his license and the Supreme Court allowed the board ten days within which to show why such a writ should not issue.¹ The board filed its answer contending that the members of the board were very busy men, needed at home by their patients, and that the evidence against Tullidge was so conclusive that no good purpose could have been served or different result reached had Tullidge been notified of the hearing and given an opportunity to resist the charges preferred against him.

All this may be true, said the Supreme Court, but the matter of depriving a person of his means of support should be considered seriously. The board of medical examiners is vested with this grave responsibility and is required to give due consideration to the rights of the accused before condemning him. The law prescribes specific requirements for doing this. If those requirements are not followed, the law is meaningless and is no longer a rule of conduct to govern the high and the low alike. We do not hold, said the court, that legal service cannot be made by registered mail or that the accused can ignore or run away from such service with impunity, but we do hold that the board has no right to proceed to the examination of a cause before it has positive proof that service has been made on the accused and reasonable time given him to employ counsel and to prepare his defense.

Tullidge contended that the charge on which his license was revoked was not warranted by law and that the charge of "scandalous conduct tending to the destruction of good morals" for which he was court-martialed was not a charge involving moral turpitude as contemplated by the law under which his license was revoked. Moral turpitude, said the court, involves the idea of inherent baseness or depravity in the private social relations or duties owed by man to man or by man to society. It has also been defined as anything done contrary to justice, honesty, principle or good morals. It often involves, however, the question of intent as when an act is unintentionally committed through error of judgment, when no wrong is contemplated.

¹ State ex rel Tullidge v Hollingsworth (Fla) 138 So 372 abstr J A M A 99 588 (Aug 13) 1932

plated The question whether Tullidge might have defended himself on the ground that the charge on which his license was revoked was not warranted by law or that the offense for which he had been convicted by court-martial was not an offense involving moral turpitude was not, however, presented in such form as to authorize the Supreme Court to express an opinion.

Tullidge's petition for a writ of mandamus directing the board of medical examiners to restore his license was granted.—*State ex rel Tullidge v Hollingsworth (Fla)*, 146 So 660

"Poisoning" in Relation to Insurance Construed.—The defendant insurance company insured the life of one Urian. The policy provided for the payment of double indemnity to his widow if the death of the insured was caused by external violent and accidental means other than poisoning. The insured accidentally inhaled carbon monoxide while working on his automobile and death followed. His widow sued for the double benefits payable in event of accidental death, ignoring the provision of the policy that relieved the insurer of the payment of such increased benefits if accidental death resulted from poisoning. Judgment was given in her favor and the insurer appealed to the Supreme Court of Pennsylvania.

According to the trial court, ordinary persons, in using the word "poison," have in mind something taken into the stomach, not germ poisons, disease poisons nor gas poisons, the word "poisoning" was used in the policy to mean something taken through the mouth into the stomach, the parties making the contract did not contemplate poisoning by gas, and the word "poisoning" refers to a deliberate act, not to the taking of poison accidentally. But with these conclusions of the trial court the Supreme Court did not agree. According to the weight of authority, said the Supreme Court the taking of poison by accident or mistake is within the meaning of an exception relieving an insurer from liability as much as is the taking of poison by design, although some cases hold the contrary. When an insurance policy is clear and unambiguous and names as a condition exempting the insurer from liability something that is simply a potential cause of injury or death, and makes no reference to any possible act or possible omission by the insured or any other person in relation to that cause, either intentional or unintentional, and when injury or death results from that cause, no recovery can be had under the policy, unless there is in it some other provision authorizing such recovery. The judgment of the trial court in favor of the beneficiary was reversed so far as it required the payment of double benefits.—*Urian v Scranton Life Ins Co (Pa)*, 165 A 21

Insurance Total Disability Defined.—The plaintiff sued the defendant insurance company on a policy which provided certain benefits if the plaintiff should suffer disability wholly preventing him from engaging in any business or occupation or performing any work for compensation. The insurance company contended that even if the plaintiff was unable to perform his usual business he could not recover unless there was evidence that his disability prevented him from carrying on any kind of work for compensation. Disability clauses said the Supreme Court of Arkansas do not define disability in such a way that the insured must become helpless before he can claim the benefits under them. Such disability is meant as renders him unable to perform all the substantial and material acts of his business or the execution of them in the usual and customary way.—*Guardian Life Ins Co v Johnson (Ark)*, 57 S W (2d) 555

Evidence Admissibility of Statements Made by Examinee to Examining Physician.—A physician can testify as to symptoms and conditions of injury or disease made known to or discovered by him in treating his patient. But when an injured person for the express purpose of qualifying a physician to testify in his behalf in a personal injury suit makes statements as to subjective pain and suffering not disclosed to the physician by other and independent means there exists both motive and opportunity for the patient to mislead or feign. Under such circumstances the statements of the patient are clearly eliciting and hearsay and should not be admitted in evidence.—*Clarks v State (Texas)*, 7 S W (2d) 207

CENTRAL SOCIETY FOR CLINICAL RESEARCH

Sixth Annual Meeting held in Chicago Oct 27 and 28 1933

The President DR M A BLANKENHORN, Cleveland, in the Chair

Food Sensitization Dermatoses (Eczema)

DR CLEVELAND J WHITE, Chicago Specific food or foods have been found to be of either primary or secondary etiologic importance in 128 out of 487 cases of so-called eczema. Thirty-four were treated with the specific food propeptan. It was of decided benefit in 85 per cent but of no value or produced an urticarial or symptomatic flare up in the remainder. In this study the clinical manifestations of food sensitization dermatoses were reviewed and the importance of cutaneous food tests and elimination diets discussed.

DISCUSSION

DR LEE FOSHAY, Cincinnati I should like to inquire whether propeptan is used only once and whether immediately after the exclusion of the sensitizing foods from the diet.

DR CLEVELAND J WHITE, Chicago The propeptan therapy is well discussed in Urbach's book, which has been translated into English by Dr F M Schmidt of Chicago. The specific food propeptan tablet is taken forty-five minutes before eating a portion of the food itself. This amount is regulated by the presence of any eruption following this ingestion. My criticism of the propeptan is the almost total ignorance of its method of preparation. I believe that eventually we shall be able to prepare our own specific food peptones, thus making it economical enough to be used on a larger scale when such desensitization is necessary.

Influence of the Liver on the Metabolism of Bile Acids

DR J L BOLLMAN Rochester Minn Bile acid excretion has been studied under several experimental conditions. The excretion of bile acids in the bile collected by the external fistula of Rous and McMaster or by choledoco-ureterostomy is quite constant day by day. It is little influenced by diet. Almost quantitative recovery of bile acids administered by vein or by mouth is obtained within twenty-four hours. Small amounts of certain toxic substances—chloroform carbon tetrachloride and tetrachlorethane—which specifically damage the liver cause a marked decrease in the excretion of bile acids without producing any other evidence of hepatic dysfunction. Ligation of the common bile duct causes urinary excretion of bile acids in almost constant amounts daily. This amount, however, is only about half of that excreted by dogs with external biliary fistulas. The normal animal appears to be able to destroy large amounts of bile acids, since large amounts may be fed over long periods without the appearance of bile acids in the urine or feces. Bile acids fed or injected into animals with obstructive jaundice are only partly recovered in the urine. After complete removal of the liver the administration of bile acids is followed by the excretion in the urine of the complete amount of bile acid given. The liver appears to be the site of destruction of bile acids in the body. Bile acids, unlike bile pigment do not appear in the blood or urine following complete removal of the liver. The significance of this fact is doubtful since there is a similar depression of bile acid formation following the performance of a biliary fistula or ligation of the common bile duct.

DISCUSSION

DR M A BLANKENHORN, Cleveland Dr Bollman answered the question that I would ask as to the aid in differentiating

intrahepatic and extrahepatic causes of jaundice. It has always appealed to me as a likely aid. I should like to ask Dr Bollman whether or not in obstructed animals with the common duct tied, the feeding of bile salts has added to the intoxication that might be analogous to chloremia. That point comes up in the matter of the giving of ox-gall to patients. I should like to ask whether his work has made any contribution to that point.

DR G O BROWN, St Louis. I should like to ask what method of extraction of blood was used to carry out the test for bile salts.

DR SIDNEY A PORTIS, Chicago. I should like to ask Dr Bollman whether coincidentally in his experiments of biliary fistula and the feeding of bile salts, he noticed any increase in the excretion of bile following the feeding of bile salts.

DR J L BOLLMAN, Rochester, Minn. In reference to the chairman's question about the feeding of bile salts having any effect on the clinical well being of the animal, I have given as much as 5 Gm of sodium glycocholate daily to ordinary sized dogs and have observed no untoward effects. Even in animals with obstructive jaundice large amounts of bile salts appear to be without any deleterious effect. I know of no reason to anticipate serious consequences following bile salt administration in human beings. Dr Brown asked about my method for determination of bile salts in the blood. Five cubic centimeters of blood is precipitated with eight volumes of alcohol and centrifugated. The supernatant fluid is evaporated to dryness and taken up in 10 cc of alcohol. This is centrifugated and again evaporated to dryness. Sulphuric acid and furfural is added (Gregory method) and the mixture heated in a test tube at 65 degrees for thirty minutes. A definite blue color indicates the presence of bile salts. Normal blood gives no color. I have not been able to get the final solution clear enough for colorimetric comparison but have been able to match the unknown tubes with a series of standards prepared in the same way after the addition of different amounts of bile salts to normal blood. I have observed an increased flow of bile following administration of bile salts to animals with biliary fistula. Bile salts appear to be a fairly satisfactory chologogue. However this action is not always obtained. I would say, taking in a large number of experiments that perhaps one or two animals out of ten will fail to give an increased flow of bile following bile salt administration. I do not know why these animals at times fail to respond to this stimulus.

A Biochemical Study of the Size of the Liver and Spleen in Disease for Differential Diagnosis

DR MOSES BARRON, Minneapolis. This study consists of a careful statistical analysis of the weights of the liver and spleen as found in various diseases. A series of 16,000 post-mortem records covering a period of ten years from the department of pathology at the University of Minnesota Medical School was reviewed, from which there were chosen 312 cases of apparently normal adults killed suddenly from accidental causes. This group furnishes the normal weight standard. Another group of 489 cases is classified, in which there was also no abnormality found other than hemorrhage. This group shows the effect of hemorrhage on the weight of these organs. The principal study consists of a group of 5,843 cases subdivided into the various diseases, and the weights of the livers and spleens are presented so as to give the percentage of each group falling into various weight zones. It is found, for example, that leukemia gives the largest percentage of very large spleens with practically no spleen falling in the lower weight zones. Toxic goiters give almost as large spleens as amyloid disease. Carcinoma, both primary and secondary, and melanoma produce the largest livers, while malignant conditions that produce cachectic states result in the smallest livers and spleens. This study on a biometric basis is found to be superior to the simple statistical analysis made of the same group of cases (The Importance of Hepatomegaly and Splenomegaly in Differential Diagnosis, *Arch Int Med* 50 240 [Aug] 1932) and is a great aid in the differential diagnosis of many disease states.

DISCUSSION

DR JOHN FOULGER, Cincinnati. I wonder if Dr Barron knows of Barcroft's work on the spleen of the dog, which showed that during pregnancy the spleen was greatly shrunken. How does Dr Barron reconcile this fact with his results showing spleens in abortion cases to be about 30 per cent above normal size?

DR FREDRICK A WILLIUS, Rochester, Minn. I should like to ask Dr Barron whether in his studies of the weight and ranges of normal livers and spleens he has considered the height and weight of the individual.

DR MOSES BARRON, Minneapolis. The height and weight were not taken into consideration in this study. Another study is contemplated for this purpose. The present study simply shows the weights of liver and spleen for adults over 20 years of age, irrespective of their height or weight. In regard to the experiment cited relative to the size of the spleen in pregnancies I have no data on this particular phase. Our studies were on septic spleens following abortion, therefore it was not the pregnancy that influenced the size of the spleen but the associated septicemia. An interesting fact, however, is shown in this chart in that the spleens in cases of subacute bacterial endocarditis are definitely larger than those from simple septicemia. An enlarged spleen is therefore more characteristic of subacute endocarditis.

A Possible Relationship Between Antisyphilitic Treatment and Portal Cirrhosis

DR C W BALDRIDGE, Iowa City. In this study of portal cirrhosis every effort was made to include only undoubted cases. Thirty-six such cases were found in the records of the University Hospital for the past twelve years. In sixteen of these the diagnosis was confirmed by necropsy and in two others it was confirmed at operation. Fifteen of the thirty-six patients had syphilis. Of these fifteen patients with syphilis two had had no treatment two may or may not have had treatment and eleven had treatment which in most instances was intensive. Active antisyphilitic treatment with mercury and arsphenamine was begun an average of six years before the patients were found to have portal cirrhosis, and the average duration of treatment with arsphenamine was more than two years. Four of the patients in whom cirrhosis followed antisyphilitic treatment used no alcohol at all (three were women) and only three used alcohol excessively and regularly. In one patient a minister's wife, who used no alcohol and who did not have syphilis, cirrhosis developed after antisyphilitic treatment. Circumstances that tend to incriminate the antisyphilitic treatment as the principal etiologic factor in the production of portal cirrhosis in most of the twelve cases in this series were studied.

DISCUSSION

DR E G WAKEFIELD, Rochester, Minn. I should like to ask Dr Baldridge whether he studied the effects of repeated doses of the arsenicals or mercurials carried on over a long period of time to determine whether there were changes in the liver of a cirrhotic type.

DR C W BALDRIDGE, Iowa City. Arsphenamine does produce liver damage in animals (Craven E B Jr *Bull Johns Hopkins Hosp* 48 131 [March] 1931). The question comes up as to whether or not such damage will eventually result in cirrhosis or a lesion which is often called cirrhosis. If Mallory's classification is followed I believe that toxic cirrhosis will develop. I do not know that any of the animals have been followed long enough to develop a typical toxic cirrhosis, such as is seen in the human being.

The Urinary Excretion of Iodine in Toxic Goiter

DRS GEORGE M CURTIS and FRANCIS J PHILLIPS, Columbus, Ohio. The normal urinary excretion of iodine of hospital patients in central Ohio ranges from 25 to 75 micrograms daily. It is at a normal range in patients with nontoxic nodular goiter and also in those with nontoxic diffuse colloid goiter. In patients with diffuse hyperplastic goiter with severe hyperthyroidism, it is greatly increased during the early exacerbation of untreated toxicity. It is increased during induced

hyperthyroidism and in patients with toxic nodular goiter. The urinary excretion of iodine rises immediately following thyroidectomy. The rise soon subsides. When iodine is administered quantitatively to patients with diffuse hyperplastic goiter with hyperthyroidism, the urinary excretion of iodine is low during the first few days. There ensues an increasing excretion of iodine as clinical improvement ensues. This is interpreted as due to the taking up of iodine by the depleted gland and tissues. The cyclic changes in the urinary excretion of iodine in women are accentuated in patients with toxic goiter.

DISCUSSION

DR H L ALT, Chicago. Is the urinary excretion of iodine increased in other conditions in which there is a high metabolic rate, such as leukemia or fever?

DR LOUIS LEITER, Chicago. I should like to ask whether or not in the case of hyperthyroidism following thyroid administration there was an increase of iodine in the urine. Also, what happens to the urinary excretion of iodine in a patient who has no hyperthyroidism at all but undergoes a major operation? And, from a theoretical standpoint, do the authors have any idea as to the basis of the therapeutic effects of iodine on hyperthyroidism when the blood is full of iodine and, apparently, the gland is unable to take it up from the blood?

DR W O THOMPSON, Chicago. I congratulate Drs Curtis and Phillips for making observations of fundamental importance. I notice that in normal individuals the iodine in the urine varied from 25 to 75 micrograms daily, a variation of 300 per cent. I wonder whether this variation might be accounted for largely by differences in the amounts of iodine in the food ingested.

DR WARREN B COOKSEY, Detroit. I wonder whether the authors have shown any correlation between the iodine content of the glands that were removed by thyroidectomy and the iodine content in urine and blood. A few years ago two of us in Detroit did some work in which we attempted biologically to assay thyroid glands that were removed at the operating table because of thyrotoxicosis. We fed these desiccated glands to tadpoles in order to ascertain what rate of metamorphosis would occur with the different specimens. We found absolutely no correlation between clinically toxic goiter and the iodine content of those glands as they were biologically assayed. In other words, the higher the iodine content according to the assay of thyroid extract, the greater stimulus to metamorphosis would be expected. That did not hold true, even in patients who had not been given compound solution of iodine. Some of the glands of very high iodine content stimulated metamorphosis much less than those of lower iodine content.

DR JOSEPH L MILLER, Chicago. There has been a recent report in the German literature on this problem and the results recorded are in accord with those of Drs Curtis and Phillips. They determined not only the iodine in the urine but the amount in the stool and the amount in the perspiration. This loss through these various channels may be so great immediately after a subtotal thyroidectomy that the organic iodine practically all disappears from the blood. This has raised the question of whether or not reaction that occurs after the operation may be due to a hypothyroxemia.

DR ROGER MORRIS, Cincinnati. I should like to ask the authors whether any observation has been made on patients presenting symptoms and physical signs of thyrotoxicosis when the metabolic rate was normal or subnormal. In the last few years I have been interested in patients of this type. In the charts that were shown all the patients had a high rate. Is the iodine secretion similar in patients with increased metabolic rate and in patients with a normal rate who present symptoms and signs of thyrotoxicosis? It would be interesting to try to discover whether or not the metabolic rate and the iodine excretion run parallel.

DR G M CURTIS, Columbus, Ohio. We have investigated the iodine metabolism in one patient with goiter. More iodine is excreted in the urine than in the stool. Daily administration of 10 mg of iodine to patients with toxic goiter may increase the stool excretion to 300 micrograms a day whereas the urinary excretion may rise to 7 mg a day. In two patients

operated on for other causes than toxic goiter we have observed an increased postoperative urinary excretion of iodine. This increase is not so great as occurs in patients operated on for goiter. We find no direct correlation between the level of blood iodine and that of the basal metabolism in normal individuals in patients without thyroid disease or in patients with hyperthyroidism. An explanation of this may be drawn from the investigations of Sturm and of Lunde. They have shown that there are two forms of blood iodine, one alcohol insoluble and the other alcohol soluble. The alcohol-insoluble form may be the thyroid hormone. In regard to the instance of induced hyperthyroidism, there would appear to be no essential difference between giving so much desiccated thyroid by mouth and thyroid hypersecretion. We have estimated the amount of iodine in the 10 grains (0.65 Gm) of thyroid tablets as about 240 micrograms. The blood iodine is increased in patients with hyperthyroidism and yet amelioration of the symptoms ensues on iodization. This raises the iodine paradox, which is best explained by the work of Lunde. During iodization the alcohol insoluble form decreases, whereas the alcohol-soluble portion increases. The diffuse hyperplastic goiter is iodine poor. When iodine is administered, its iodine content increases. Microscopically, the gland presents a marked increase in colloid. Dr Thompson has pointed out the significance of the food iodine. The iodine content of the foods administered in the University Hospital is being determined. Certain of these contain more iodine than others. One microgram of iodine as desiccated thyroid accelerates tadpole metamorphosis. Iodine alone does not stimulate metamorphosis. We would point out that in lymphatic leukemia there is an elevation of the basal metabolism as in toxic goiter. There is a lymphocytosis as in toxic goiter and also a response to iodine. It was discovered by Sturm that in lymphatic leukemia there is an elevation of the blood iodine. We have confirmed this observation.

Calorigenic Effects of the Oral Administration of Thyroxine in Various Forms

DRS W O THOMPSON and P K THOMPSON, S B NADLER, PH D, DR S G TAYLOR III and L F N DICKIE, B S, Chicago. Observations have been made which show that contrary to the generally accepted opinion, thyroxine has a very definite effect on the basal metabolism when administered by mouth but that its effect varies greatly according to the form in which it is given. Compared with the effect of intravenous administration of an alkaline solution of thyroxine, the oral administration of pure thyroxine produces only about one one hundred-and-fiftieth as much effect, while that of the monosodium salt produces about one fourth as much effect and that of an alkaline solution about two thirds as much effect. (When thyroxine is dissolved in an excess of sodium hydroxide, the disodium salt is presumably formed.) Single large doses of desiccated thyroid by mouth, suspended in distilled water, have, on the average, the same effect as doses of thyroxine in alkaline solution containing the same amount of iodine. However when desiccated thyroid is treated with a weak solution of sodium hydroxide, its effect may be enhanced in some instances. A peptide of thyroxine prepared by tryptic digestion of desiccated thyroid has less effect when administered orally suspended in distilled water than thyroxine in alkaline solution, but when administered in a weak solution of sodium hydroxide it has an effect which at least equals that of thyroxine in the same form. From these observations it would appear that the effect of a thyroxine compound by the oral route depends on its solubility, and that solubility in turn is dependent as much on the formation of a soluble salt as on a peptide linkage. It is now possible to treat patients with myxedema almost as cheaply by the oral administration of thyroxine in suitable form as by desiccated thyroid.

DISCUSSION

DR JOHN FOLICER, Cincinnati. I should like to ask the authors whether they considered that a change in the optical properties of these amino acids particularly synthetic thyroxine, might occur in making a disodium salt solution. The authors perhaps remember the work of Cushny, which showed that optical activity and pharmacologic effect are closely related. It is quite possible that in treating synthetic thyroxine with

alkali one has considerably altered the internal properties of the compound, as would be shown by the measurement of the optical rotatory power of the initial and final product

DR W O THOMPSON, Chicago The thyroxine that we used was said by the manufacturers to be racemic, by which they meant that half of it was *d* thyroxine and half *l*-thyroxine. The thyroxine in the peptide was probably *l*-thyroxine. There are three different groups of observations which have a bearing on Dr Foulger's question. 1 Møller, Gram and Schou, and Thompson and his co-workers have found synthetic thyroxine and thyroxine as isolated from the thyroid gland by the method of Kendall (Squibb's thyroxine) to have about the same calorigenic action when injected intravenously in an alkaline solution, and the first observers have found the two to be the same spectrophotometrically. 2 Gaddum on the basis of experiments on four normal rats, concluded that *l*-thyroxine produced two and one-half times as much increase in oxygen consumption as *d*-thyroxine. 3 Salter, Lerman and Means noted that a polypeptide of thyroxine isolated from the thyroid by proteolytic digestion and presumably containing thyroxine in the levorotatory form, produced about the same increase in basal metabolism in man when injected intravenously as we had observed following the intravenous injection of Squibb's thyroxine in an alkaline solution.

Ammonia Excretion and Neutrality Regulation

DR A P BRIGGS, St. Louis It has been observed with dogs following subcutaneous administration of potassium chloride the salt of a low threshold base and a threshold acid that there is a greater increase in the urinary excretion of fixed base than of mineral acid. With this presumptive acid excess in the tissues there is a decreased excretion of ammonia. From disodic sulphate the salt of a threshold base and a no threshold acid, opposite results were obtained, i. e., a greater increase in excretion of mineral acid than of fixed base and an increased excretion of ammonia with presumptive sodium residue in the tissues. These results seem incompatible with the prevalent belief that the stimulus which excites ammonia formation is increased acidity of the tissues. They are in harmony with the view that ammonia formation is stimulated by increased local acidity in the kidney tubules.

The Ultimate Fate of Damaged Glomeruli

DRS ALAN R MORITZ and J M HAYMAN, JR, Cleveland Human kidneys obtained at autopsy were injected with iron salts and an estimate of the total number of patent glomeruli was made by Kunkel's method. The sections for histologic examination were prepared from different portions of each injected kidney, and the proportion of injected and obliterated glomeruli was determined. From these two measurements the total number of glomeruli, including intact glomeruli and glomerular scars, was estimated and compared with the number of glomeruli in normal kidneys. It was found that in arteriolar nephrosclerosis and in chronic diffuse glomerular nephritis there has been a complete disappearance of as many as 50 per cent of the glomeruli.

DISCUSSION

DR R W SCOTT, Cleveland I should like to ask whether the authors have found any correlation between the number of fibrosed glomeruli and the clinical picture of uremia. Is the number of glomeruli different in individuals dying of uremia from inflammatory nephritis as compared to those dying in uremia from nephrosclerosis?

DR LOUIS LEITER, Chicago I should like to ask whether there was any correlation between renal function during life and the number of vanished glomeruli in those cases in which the sum of patent and obliterated glomeruli was significantly less than the average normal number of glomeruli.

DR J M HAYMAN, JR, Cleveland I think I can answer the first two questions. In chronic vascular disease and chronic nephritis there is a rough parallelism between reduction in the urea and creatinine tests of kidney function and the number of glomeruli. In these two diseases the patients usually do not go into uremia until the glomeruli have been reduced to 25 or 33 per cent of the normal number. There is another

type of uremia, that of prostatic obstruction or accompanying infection, in which the patient will have an approximately normal number of glomeruli, which under the microscope appear normal. In reply to Dr Scott's question about young persons with so called malignant nephrosclerosis who quite suddenly go into uremia, in this condition we did not find anything like as marked reduction in the number of glomeruli as in the chronic cases. But our estimations do not give us any measure of the amount of filter surface in the remaining glomeruli. In answer to Dr Leiter, any glomerulus that is situated at all must be counted as a glomerulus even though the filtering surface may be reduced.

A Case of Simmond's Disease (Cachexia Hypophysaeopriva) with Recovery

DR CECIL STRIKER, Cincinnati A white girl aged 17 years whose weight on admission was 48 pounds (22 Kg) presented a basal metabolic rate of -48, flat dextrose tolerance and slight secondary anemia. A roentgenogram of the sella showed suggestive cystic degeneration. Roentgenograms of other bones showed marked calcium deficiency. The patient had been on a regimen of thyroid and ovarian extract prior to the examination without any improvement. She had very marked abdominal cramps with constipation and had a well marked cathartic addiction, taking as many as fifteen Peen-a-Mint tablets and three enemas daily without bloody diarrhea. She was placed on 1 cc of soluble extract from the anterior lobe of the pituitary hypodermically, daily, and continued on this for four months with very striking improvement. Examination shows that the patient now weighs 135 pounds (61 Kg), has been completely rehabilitated and is apparently cured of the intestinal condition.

DISCUSSION

DR JOSEPH L MILLER, Chicago I should like to ask the dosage of anterior pituitary. What did the roentgen examination of the colon show?

DR W O THOMPSON, Chicago I am interested in knowing whether this girl had starved herself before she was seen. I remember very well a girl who was similar to this patient. She was a schoolgirl of 17, who weighed 120 pounds (54 Kg). She had a sensitive nature and, because of the constant teasing of her companions in school about her plumpness began to diet. She gradually ate less and less until finally her appetite disappeared and her weight dropped to 65 pounds (29.5 Kg). Menstruation ceased and her metabolism dropped to minus 45 per cent. She was virtually skin and bones like the patient presented by Dr Striker. When she voluntarily increased her intake of food her weight promptly rose to 100 pounds (45 Kg). In view of the fact that the improvement in Dr Striker's patient persisted for six months after the administration of anterior pituitary was stopped, it would be particularly important to know just what the caloric intake was.

DR C C STURGIS, Ann Arbor, Mich. I saw two cases which were reported from the University of Michigan. Neither case was treated with anterior pituitary. One case was reported in retrospect from the autopsy. The other patient was uncooperative and it was not possible to keep him under observation. This case was mistaken for myxedema and treated with thyroid extract without improvement and the patient then disappeared.

DR CECIL STRIKER, Cincinnati In answer to Dr Miller, the course of treatment consisted of daily injections of anterior pituitary for two months, then every other day for a month then once a week. She had a four months series of anterior pituitary and then none for six months. Unfortunately I cannot give the results of examination of the colon. She has moved away from the city but reports state that she is no longer addicted to cathartics. Regarding Dr Thompson's inquiry, I was interested in the same question. The patient had previously been on insulin and there was no increase in appetite following the insulin. There was no psychologic factor to be removed except the use of cathartics. Her environment has been practically the same during the entire course. She was put on a high vitamin B diet. The only factor in the course of treatment was the addition of anterior pituitary.

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers to THE JOURNAL in continental United States and Canada for a period of three days. Periodicals are available from 1925 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Transplantable Tumor of the Rat—Seccof describes a tumor that he has had under investigation since June, 1928. It appeared on the supra-orbital region of a rat and has been transplanted through nineteen generations taking in about 30 per cent of the transplants. It grows best in the peritoneal cavity. In structure it resembles a carcinoma but the type cell suggests that the tumor may belong to the endothelioma or myeloma group. Since the tumor was undifferentiated, the primary object has been to transplant it through as many generations as possible, in the hope that its structure might become more differentiated and identifiable from the standpoint of common nomenclature. To date the structure has remained unaltered and the exact nature is still unknown. While the transplantations were carried out observations and experiments were made on the influence of hereditary multiplicity of inoculations and cytologic variations in relation to takes. The author records the data on transmissibility and structure.

Abderhalden Reaction in Malignant Tumors—Sanchez made 228 Abderhalden tests with nine different types of substratum. 123 were positive, 62 negative, 20 uncertain and 23 without result. Counting all tests even those with technical errors, the diagnostic accuracy is 72.3 per cent. Of the 131 tests made with serum from patients having malignant tumors, 107 were positive, 4 negative, 11 uncertain and 9 without result. Of the 97 tests made with serum from patients having other diseases or from normal persons, 16 were positive, 58 negative, 9 uncertain and 14 without result. Of 36 tests made with substratum 1, 15 were made with serum from malignant cases, of which 11 were positive, 3 uncertain and 2 gave no result, and the other 18 were made with serum from nonmalignant cases, 3 of which were positive, 10 negative and 5 gave no result. Without counting the uncertain reactions and those given no results, the percentage of error is 11.5. Of 152 tests made with substratum D (mixture of carcinoma and sar-

coma) 88 were positive, 39 negative, 14 uncertain and 11 gave no result. Of 99 tests made with serum from malignant cases, 78 were positive, 1 negative, 6 uncertain and 6 gave no result. Of 61 tests made with serum from other patients and from normal persons, 10 were positive, 38 negative, 8 uncertain and 5 gave no result. One substratum D serum from a malignant case gave a negative result and 10 serums from other patients and normal persons gave positive results. In these 11 cases the test failed. Among the nonmalignant cases which gave positive results were 5 in which the clinical diagnoses were typhoid, epidemic (lethargic) encephalitis, respiratory infection, mastoiditis and pneumonia. In 5 cases a positive reaction was obtained at a time when the clinical diagnosis of the malignant condition was indefinite or negative. Later either the pathologic report or the surgical report proved the result of the blood test.

Moniliasis of Lungs and Stomach—Lewis describes a fatal case of pulmonary and gastric (pyloric) moniliasis accompanying a pernicious-like anemia. The patient presented a clinical picture similar to that of advanced pulmonary tuberculosis. The copious sputum contained *Monilia albicans*, type II (Stovall), in large numbers. The monilia isolated was rather pathogenic for guinea-pigs, even after more than two years of artificial cultivation. Iodides by mouth did not stop the progress of the disease, perhaps owing to the late extensive involvement when treatment was begun. More frequent study of sputums is indicated for the purpose of detecting monilia and other fungus infections of the lungs. Monilia in sputum is a rather frequent finding and is perhaps more often a nonpathogenic secondary invader. The finding of monilia should not prevent a further search for other causes of pulmonary pathologic changes.

Reticulocyte Enumeration—Schleicher proposes a new method of reticulocyte enumeration. He places twenty five parts of solution A (1 Gm of neutral potassium oxalate, 0.85 Gm of sodium chloride and 100 cc of distilled water) to five parts of solution B (1 Gm of brilliant cresyl blue, 0.85 Gm of sodium chloride, 100 cc of distilled water and 1 Gm of chlorbutanol) in a conical tipped centrifuge tube to mix them and adds several drops of blood. After thorough mixing, he allows the solution to stand from ten to twenty minutes and then centrifugates it from twenty to thirty seconds at a moderate speed. The supernatant fluid is pipetted off until a layer of fluid approximately equal to the depth of the sediment remains. The sediment is mixed well with the supernatant liquid drawn up in the pipet and one drop is discharged near the end of a slide. The stained drop is spread with the edge of an 18 mm square coverslip and the film is drawn to about 6 cm from the starting point. The relative distribution of the reticulocytes is found by dividing a piece of paper into ten columns, adjusting a 4 X eyepiece to a tube length of 190 mm and using an oil immersion objective 18 mm by 95 numeric aperture 1.3 in order to obtain the specific microscopic working field. The relative distribution of the reticulocytes will usually show about four variations in concentrations, extremely high, high, low and extremely low or absent. The objective is placed on the upper edge of the film near the starting point, the slide is moved upward in a vertical line and several fields are counted that show the highest as well as the moderately high, moderately

low and low reticulocyte concentrations. The counts of each classification are recorded in column one. When the lower edge of the film is reached, the slide is moved to the left horizontally 0.5 cm, from this point the slide is moved downward and the reticulocyte concentrations are counted and recorded in column two. Ten vertical zones are counted in this manner. If a vertical zone does not show any reticulocyte, a zero is marked in the corresponding column. There will be found approximately 150 microscopic fields in a vertical zone, and the average field shows about forty erythrocytes. When the ten reticulocyte counts have been added, the total number is referred to as the sum of reticulocytes. In the same ten fields there are 400 erythrocytes. The ratio of reticulocytes to erythrocytes is therefore the sum of reticulocytes over 400. The percentage of reticulocytes is the sum of reticulocytes over 400×100 , or the percentage equals the sum of the reticulocytes $\times 0.25$.

Exophthalmos in Leukemia—Reese and Guy report a case of lymphatic leukemia in which the ocular manifestations first led the patient to seek medical advice. The first manifestation in the sequence of events was a choroidal hemorrhage, with detachment of the retina in the left eye. Six days later an orbital hemorrhage with exophthalmos and a choroidal hemorrhage with detachment of the retina occurred on the right side. Five days later this was followed by an enormous expulsive hemorrhage in the orbit on the left side. This was of an extreme degree, the eyeball protruding beyond the palpebral aperture and literally lying on the cheek. The bulbar conjunctiva was pushed out and exuded sanguineous serum.

Because of the exposure of the eye and the resulting discomfort, an enucleation was done. At the time of the operation the orbit was found to be completely filled with blood and a microscopic examination of the globe showed the retinal detachment to be due to choroidal hemorrhage. The patient died on the fifteenth day.

Air Emboli and Artificial Pneumothorax—Cobbs, in his procedure for the prevention of air embolus developing during pneumothorax uses the Robinson type of machine and has the water level in the air bottle some 8 or 10 cm. higher than that in the pressure bottle. The procedure used is the reverse of that in giving a refill and the operating needle is fitted to the terminal connection. The stopcocks to the manometer and that controlling the flow of water between the bottles are opened. This starts the flow of water from the air bottle into the pressure bottle, with the consequent aspiration of air through the needle. With this condition established, the needle is pushed through the skin. The stopcock governing the flow of water between the two bottles is closed and the needle is carefully pushed deeper into the tissues. The parietal pleura is thus penetrated with a standing negative pressure in the needle of minus four or five. With the needle in a free space, the petcock between the two bottles is opened and during an initial compression there is, as a rule, sufficient negative pressure to draw the water from the pressure bottle into the air bottle, even with the water standing some 6 or 8 cm. higher in the air bottle. The author states that by using this technic there is no chance for an embolus even if the needle is in the lung or in a venule and that this modification is also of value when free full oscillation is not obtained, as there is no danger in opening the supply petcock while the point of the needle is adjusted or changed, seeking a full oscillation.

Cockroach as Possible Carrier of Tuberculosis—The experiments of Read show that the cockroach may be considered a possible mechanical carrier of tuberculosis, as (1) all smears of the intestinal tracts were positive, thus showing that the cockroach will eat positive tuberculous sputum, (2) these organisms when recovered from the intestinal tracts are viable, for they produced typical lesions in the guinea-pig, and (3) microscopic sections did not show the bacilli to be present in the tissues, thus showing that they remain in the intestinal tract. If tuberculosis patients and "carriers" do not properly dispose of their sputum, rags, handkerchiefs or paper expectorated into, the cockroaches may make a meal of this material and crawl away to the kitchen or pantry and thus contaminate the food. Kitchens and pantries of the neighbors may also be contaminated.

nated, because cockroaches have been known to migrate in a body from one house to another

Estimating Tubercle Bacilli in Sputum—Hughes devised a method for making a closely approximate estimate of the number of tubercle bacilli in a specimen of sputum, by obtaining a homogeneous distribution of bacilli throughout the specimen and counting the bacilli in a measured quantity (1 cmm) of the specimen. In preparing the specimen and smear, 1 cc of a 10 per cent solution of sodium hydroxide is pipetted into a 10 cc test tube and 2 cc of sputum is added, along with three glass beads. The mouth of the test tube is flamed and stoppered with a cork. The tube is placed in a shaking machine in a horizontal position and agitated. Because of the viscosity of the sputum the author has used pieces of ordinary glass tubing, 4 mm in diameter and 25 cm in length and graduated by a mark with a file to deliver 2 cc, instead of the usual type of pipet. Sputum can be readily drawn up into such a pipet by means of a Luer syringe attached to it by rubber tubing. After being digested and shaken for thirty minutes, the specimen is removed from the shaking machine and an area of 400 sq mm is marked off on the end of a 1 inch microscopic slide. This measurement introduces an error of less than 0.5 per cent. The slide is cleansed by being placed over night in a solution of 97 cc of alcohol and 3 cc of acetic acid. By means of a standard loop, one loopful of serum used to fix the bacilli to the slide and one loopful of the digested sputum are mixed together on the slide and are then spread in a uniform smear over the marked off area. The smear is dried in air, fixed by heat and stained by the usual Ziehl-Neelsen technique. Ten scattered oil immersion fields are examined and the average number of bacilli per field is estimated. This average is then corrected for the dilution of the sputum by sodium hydroxide by multiplying the number of bacilli seen per field by the factor 15.

Dermatosis After Section of Fifth Cranial Nerve—Loveman presents the history of a woman who nine months after a radical resection of the sensory root of the gasserian ganglion had two superficial 18 mm ulcers above the hair line in the posterior frontal area covered with a purulent necrotic slough. Trophic ulcerations trophic ulcers with a superimposed carcinomatous degeneration and a possible factitious dermatitis were the three clinical diagnostic possibilities. The fact that the lesions were so sharply limited to the trophic area were lateral and followed roughly the nerve distribution in males

a diagnosis of factitious dermatitis untenable. Furthermore, the fact that the condition responded to roentgen therapy and failed to recur adds to the improbability of such a diagnosis. Carcinoma was ruled out only after careful histologic studies. Large doses of roentgen rays were given because of the original opinion that the changes were epitheliomatous. In view of the previous damage to the nerve the superficial nature of the lesions and their zosteriform distribution, the author believes that atrophic disturbance best explains their occurrence. Just why the lesions responded so rapidly to roentgen therapy, he does not know.

Pituitary Extract in Treatment of Alopecia—Lord states that in a series of seventeen cases of alopecia treated with pituitary extract he has observed no evidence for or against the extract. He is sure that the study of a large series of cases of alopecia areata would reveal the fact that the average length of time required for the regrowth of hair varies between six months and a year. In the three patients whom he treated with the pituitary extract at the time of the appearance of Bengtson's article he found no evidence which might lead him to believe that the drug was of any value, and in three other patients who have since submitted to its administration the results have been such as to give him no cause for altering his view.

Bismuth Arspenamine Sulphonate in Rabbit Syphilis—The experiments of Raiziss and Severac revealed that the maximal tolerated dose of bismuth arspenamine sulphonate given intramuscularly to albino rats is from 450 to 500 mg per kilogram of body weight. This is an evidence of low toxicity. Fourteen syphilitic rabbits were cured by a single dose of bismuth arspenamine sulphonate, as judged by the method of popliteal node transfer. The minimal therapeutic dose was found to be from 10 to 15 mg per kilogram. When treated by ten weekly or twenty semiweekly injections of 3 mg of bismuth arspenamine sulphonate per kilogram, four animals were cured and three were not. Sixteen animals treated with higher doses were all cured. The minimal therapeutic dose for a series of twenty injections was found to be 4 mg per kilogram. The minimal therapeutic dose for a series of from ten to twenty injections was 5 mg per kilogram, and for a series of ten injections, 10 mg. The minimal effective single dose of arspenamine for a syphilitic rabbit, when given intravenously, was found to be from 16 to 18 mg per kilogram. The minimal effective single dose of arspenamine administered intramuscularly was 20 mg per kilogram. It appears, therefore that bismuth arspenamine sulphonate is as effective as arspenamine in experimental syphilis in rabbits.

Herpes Corneae After Hyperpyrexia—Berliner reports two cases of chronic arthritis complicated by an ocular disturbance after artificial hyperpyrexia induced by diathermy. Physical therapists report that herpes labialis is not an uncommon sequela and generally appears within twenty four hours after treatment is instituted. In the cases reported the previous ocular and otolaryngologic histories were without significance. Any attempt made to explain the manifestation of herpes in these patients would naturally be speculative. Perhaps some persons harbor the virus of herpes in an inactive form in the body, and it may be that only a favorable stimulus such as fever is required to initiate an outbreak.

Effect of Aging on Antiscorbutic Material—Gerstenberger and his associates found that fresh orange juice, spray dried as a constituent of a lactose orange juice mixture, retains its antiscorbutic potency in a practically undiminished degree for at least fifteen months after its manufacture. This conclusion was reached on the basis of observations made on groups of scorbutic guinea-pigs and in one severe case of infantile scurvy. The scorbutic guinea-pigs were cured by the daily administration of an amount of the spray dried orange juice equivalent to 3 cc of fresh orange juice, and the human infant by the giving of a daily dose equal to 45 cc of fresh orange juice. Fresh lemon juice spray dried as a constituent of an acid protein milk to which is added at the time of manufacture 20 cc of lemon juice per liter, possessed, from five to twenty-three months after its manufacture, antiscorbutic potency adequate to cure scurvy in six scorbutic infants, as judged clinically and roentgenologically. The weight curves in the two infants who were decidedly underweight responded with an immediate, decided and continuous upturn, whereas the weight curves of the four infants who were not so much underweight did not so respond even though the clinical and roentgenologic symptoms of scurvy had disappeared. In two of these four infants, additional administration of the antiscorbutic vitamin in the form of fresh orange juice did not alter the weight curve at the time. Infections that were present in these infants on a non-scorbutic basis were accepted as the principal cause for the irregular weight curves. These six infants received daily at different periods the equivalent of from 9 to 24 cc of lemon juice in the form of acid protein milk. No case of scurvy in infants fed the acid protein milk has so far come to the authors' attention. This observation indicates that this milk is adequately antiscorbutic.

Retardation in Ossification of Carpal Centers—Hess and Abramson report an instance of prolonged retardation in the development of the carpal centers in two brothers. In the

older brother, as late as 8 years of age but two centers had appeared at the wrist and no progress had been made in this respect for two years. Suddenly during the ninth year, from winter to autumn, a spurt in ossification came about. Films taken in November of this year revealed the presence of five centers in the left and six in the right wrist, in addition to new centers at the distal ends of the ulnas, the appearance of which had been delayed by approximately two years. No adequate explanation can be suggested for this sudden increase in ossification. The boy's height had remained the same, but his weight had increased 6 pounds and there was an undoubted improvement in his general condition. The younger patient was never so marked a case of carpal retardation, having three carpal centers instead of five or six at 5 years of age. He caught up to the normal gradually, so that at 7 years he approached closely to the standard, except for a delay of the distal epiphyses of the ulnas. Whereas the older patient was somewhat below the average for height-weight-age, the younger was somewhat above, tending to be stout. His metabolic rate, however, was slightly above rather than below the average. It may be added that the development of the carpal centers of both parents appeared normal.

Fruit and Vegetable Feeding—Schultz and his associates state that a study of the iron metabolism of three normal infants, ranging in age from 5 weeks to 7 months, has shown that vegetable (spinach) or fruit (apricots) feeding in addition to the milk formula exerts no significant effect on the amount of iron retained by the infant. Such feeding increased the iron intake from 60 to 171 per cent. The hemoglobin concentration and the number of erythrocytes in the blood were within or above the normal range for infants of this age and were not raised by the vegetable or fruit feeding. A study of the effect of such feeding on an anemic infant, 23 months old, who had been living on an almost exclusive milk diet has shown a lack of effect in the case of dried spinach but a marked increase in retention of iron when apricots were added to the diet, an effect that disappeared again after wheat germ extract was included. The effect in each case is related to the amount of fecal matter eliminated in the period of metabolism. The hemoglobin concentration and erythrocyte count of the blood were not improved during the course of such feeding. A large increase in the concentration of soluble iron in the diet of the anemic infant, brought about by adding ferric ammonium citrate, resulted in a large increased retention of iron but, up to the end of three weeks on the diet, only a slight increase in the number of erythrocytes had occurred, and practically no change in hemoglobin concentration. When the diet of the anemic infant was further supplemented by liver, the retention of iron was increased still more. The retention in this instance was accompanied by a rise in hemoglobin from 6 to 91.

Phrenic Nerve Interruption for Tuberculosis—Of the 654 patients who have had a phrenic operation for tuberculosis from three months to six years ago, the present status of 612, or 93.5 per cent, is known to Nehrl and Alexander. Phrenic operation was used alone in 302 cases and, in addition, in three cases of the childhood type of tuberculosis and in three cases

on both sides, but on the second side only after diaphragmatic motion returned following a temporary interruption of the nerve on the first side. Of these, 272 have been traced, 34 per cent are apparently cured or arrested, 35 per cent are apparently arrested, quiescent or improved, 12 per cent are stationary and 5 per cent are worse, 14 per cent of the patients are dead. There were 215 cases with pulmonary cavity in which phrenic paralysis alone was given an adequate opportunity to close the cavity. It succeeded in 38 per cent. In sixty-five of the 181 traced cases in which a phrenic paralysis was used following an unsatisfactory pneumothorax there was no cavity, 42 per cent are arrested and 50 per cent are improved, and 7 per cent of the patients are dead. The cavities of 59 per cent of the 116 patients who had had cavities are closed. Of the forty-seven cavities that remained open, 51 per cent are still open or the patients are dead and 49 per cent have been closed by thoracoplasty, extrapleural pneumonolysis, multiple intercostal neurectomy or scalenectomy. An initial phrenic paralysis failed to cause satisfactory improvement of sixty-six patients, for whom pneumothorax, thoracoplasty or other supplementary operation was subsequently added. In sixty-seven cases, phrenic operation was used concomitantly with thoracoplasty, extrapleural pneumonolysis, intercostal neurectomy or scalenectomy. The clinical results obviously owe more to the major operations (except perhaps scalenectomy) than to the phrenic operation. In the entire series, phrenic paralysis fulfilled the authors' expectation of it, which ranged from mere palliative symptomatic relief to complete arrest of the tuberculosis in 58 per cent, partly fulfilled it in 6 per cent, failed to fulfil it in 30 per cent, and in 5 per cent the result is unknown. Phrenic paralysis was neither directly nor indirectly responsible for the death of any patient. The only severe, permanent complication of the operation was a dyspnea that has persisted for eighteen months. In one case the operation was immediately followed by extension of a few active lesions in the contralateral lung which was checked by induced pneumothorax. The results have been in limited lesions that were relatively fresh and that contained fibrous tissue that was young enough to be still capable of considerable contraction. The least satisfactory results have been in extensive fibrotic lesions with large stiff-walled cavities. The authors are convinced that phrenic paralysis is of genuine value.

Behavior of Bronchopulmonary Smooth Muscle—The investigations of Butler corroborate those of Luisida that spontaneous pulmonary contraction can be accepted only when it occurs in lungs isolated from the rest of the body and in the absence of any vagal stimulation. It is more apt to occur in lungs that have been previously inflated to a moderate degree. The author investigated also the response to vagal stimulation, the response to intrapulmonary pressure and the response to external compression. From these observations he concludes that pulmonary systole and diastole has been proved to be a factor in the normal mechanism of respiration the systole occurring during expiration and aiding in the expulsion of air from the lungs. Stimulation of the vagus causes contraction of bronchopulmonary smooth muscle. The normal stimulus to contraction of bronchopulmonary smooth muscle is distention of the lung by inspiration. An additional stimulus not encountered under normal conditions is external compression of lung tissue. Spontaneous contractions may occur in isolated lungs without any external stimulation.

Method of Closed Prostatectomy L S Nelson Salina—p 302

Method of Closed Prostatectomy—Nelson describes a method for closed prostatectomy in which a transverse incision is made about 1½ inches above the pubis giving an exposure wide enough for visibility. A catheter is left in the urethra and the prostate is grasped securely with a tenaculum the capsule is opened posterior to the urethral orifice and the gland is enucleated. Care is used in preserving as much of the capsule as possible. After the gland is enucleated a hot sponge

is placed in the prostatic bed for a few minutes and held there under slight pressure. Then, with a boomerang needle two sutures are placed deep in the prostatic capsule, one at 8 o'clock and one at 4 o'clock with the pubis considered 12 o'clock on the dial, then one or two deep transverse sutures are placed beneath the catheter, passing below the capsule, which may be picked up and elevated somewhat for the placing of these sutures, which pass through the anterior capsule and, after placement, both are tied moderately over the catheter and capsule. Suction may be used to improve visibility. Great care must be used, especially with the lateral sutures, to avoid the rectum. These sutures when properly placed will control hemorrhage. If capsule is abundant a flap is picked up at 6 on the clock dial and drawn toward the urethra, where it is fastened deep in the prostatic bed. This furnishes a fairly good new posterior urethra. After this is accomplished a silkworm-gut suture is placed through the urethral catheter and not tied, both ends being clamped outside the abdominal wall. The bladder wall is then tightly closed around these two strands of suture with a number 1 ten-day chromic gut in interrupted sutures. A number 2 chromic suture is used for the fascia, plain catgut for the subcutaneous tissue and a nonabsorbable suture for the skin. All these are interrupted sutures. The after-care of the patient is somewhat variable but usually little irrigation is needed. If clots form, irrigation is used moderately and carefully so as not to distend the bladder, which might produce a leak. The author has had no complication, no hemorrhage and no leakage from the bladder.

Lateral Sinus Thrombophlebitis—Greenfield reports two cases. One presented symptoms of an acute surgical mastoid. At operation the author found a large perisinuous abscess. The sinus was bathed in a pool of pus and its wall was thickened and covered with an abundance of mushy granulations. At one point these granulations were necrotic and black. The sinus plate was removed until normal sinus wall was visible in the circumference of the diseased area. Following the mastoidectomy the patient had a normal postoperative course and, after being afebrile four days, was discharged from the hospital. Two weeks later he had a chill followed by a quick rise in temperature to 105 F. A blood culture taken immediately on admission was reported positive for *Streptococcus haemolyticus*. The jugular vein was tied and the lateral sinus was opened and drained and a large well organized thrombus was removed from it. At the end of four days the temperature was normal and remained so until the eighth day. Blood cultures taken during this period were reported negative. On the ninth day the patient again had a chill and his temperature rose to 105 F. The blood cultures were again positive for *Streptococcus haemolyticus*. The mastoid wound was opened and the disease was found to have extended backward involving the torcular end. The lateral sinus was uncovered backward until healthy sinus wall was encountered. The exposed lateral sinus was incised and drained and a number of well organized thrombi were removed. After this operation the patient went on to an uneventful recovery. In the other case a diagnosis of thrombophlebitis of the sinus and bacteremia was made before the primary mastoid operation. There was a history of chills, a septic temperature, a recent acute otitis and finally a positive

blood culture soon after admission to the hospital. At the time of operation the otoscope revealed a resolving middle ear. When the jugular vein was ligated, a badly broken down mastoid was found. There was a fistula in the lateral sinus, from which free pus exuded. The sinus was uncovered and all thrombi were removed. Free bleeding was obtained from the torcular end only. After a week of irregular temperature the blood cultures became negative and it appeared as if the patient was going on to an uneventful recovery. However, on the tenth day the patient had a chill, followed by a rise in temperature to 106 F. The blood culture was positive. The wound was reopened and it was found that extension had taken place in the torcular end. The cortex over the lateral sinus was removed until healthy sinus wall was encountered. Some organized thrombi were removed and the diseased portion of the sinus was slit widely open. Free bleeding was obtained from the torcular end only. The patient then went on to recovery after a ten-day stormy course.

Value of Calcium in Preoperative Preparation—Evans presents a preliminary report on the routine use of calcium in preoperative preparation. Each adult patient is instructed to eat a sufficient amount of plain food (meat once a day, not fried), to drink at least one glass of milk with each meal, six glasses of orange juice daily, 2 and 3 ounces of stick candy daily, to take deep breathing exercises at least three times each day, to see that the bowels move every twenty-four hours and to sleep at least nine hours each night. On the morning of the third day before operation, each adult patient receives a

sufficient amount of calcium so that there will be a slight hypercalcemia at the time of operation. 3 Gm of calcium gluconate by mouth immediately after each meal. On the night before operation, 10 cc of a sterile 10 per cent solution of calcium gluconate is given intramuscularly and a sufficient amount of alkali so that the urine will be slightly alkaline on the morning of operation. A plain soapuds enema is given on the evening before operation, and at bedtime 0.1 Gm of phenobarbital is given by mouth. Three quarters of an hour before the operation each patient receives from 0.008 to 0.016 Gm of morphine sulphate intramuscularly. After the operation, a retention enema of from 500 to 800 cc of tap water is given. As soon as the patient begins to react from the anesthesia 10 cc of a 10 per cent sterile solution of calcium gluconate is given intramuscularly and the patient is placed in a slight Fowler position. No abdominal binders or tight abdominal dressings are used. Fluids, if desired are given immediately after operation. The patient is turned on the side every three or four hours and during the first four or six days is made to take a series of deep breaths three or four times a day. During the first three or five days especially in upper abdominal operations, a sufficient amount of morphine sulphate is given intramuscularly to prevent any sharp pain, restlessness or fear. A small rectal tube is used if there is any distention. Enemas or cathartics are given on the third or fourth day after operation. Patients are catheterized if they do not void within twelve hours after the operation, and every eight hours until they void voluntarily. Dressings are not changed except to remove drains and sutures.

Whole Animal Exposures to Gamma Rays—In order to determine some of the biologic effects of whole body exposure to penetrating X-rays, unaccompanied by softer radiation of practical interest in connection with the recent development of high voltage roentgen tubes, Whitman exposed a group of sixty-seven rats to the radiation from 6 Gm of radium highly filtered by 16 mm of lead 1 mm of platinum, 1 mm of brass and 5 mm of celluloid. Another group of sixteen rats was exposed to 25 Gm of radium filtered by 1 mm of platinum and 1 mm of brass, giving a similar exposure to the hard gamma rays, with the addition of such soft components as penetrate 1 mm of platinum and 1 mm of brass. The lethal exposure was found to be four hours for 6 Gm of radium, with filters, for a distance of 62 mm to the midposition of the rat. The minimum exposure which could be detected by blood counts was found to be from one twentieth to one thirtieth of a lethal dose. For rats that have reached maturity before exposure the sterilizing dose does not appear to be less than the lethal dose.

Breeding experiments were carried out with the result that the first progeny of rats exposed to more than one tenth of a lethal dose showed a small increase in the number of abnormal offspring. Dental films enclosed in a 7 mm lead cassette were calibrated in terms of the lethal rat dose to serve as a more sensitive measure of the amount of exposure of laboratory workers to such hard radiations.

*Localization of Spirochaeta Pallida in the Brains of Rabbits Following Intraspinal Injection of Testicular Tissue and Physiologic Salt Solution G W Raiziss and Marie Severac Philadelphia—p 195

Localization of Spirochaeta Pallida—Raiziss and Severac attempted to render the central nervous system of the rabbit more easily penetrable to spirochetes by injection of normal testicular extract. Six rabbits received an intraspinal injection of an emulsion of testicular tissue of normal rabbits. Three were inoculated intratesticularly and three intravenously, by the usual method, with syphilitic testicular tissue (Nichols strain). From six to seven weeks later testicular lesions appeared and when the brains of the animals were removed and emulsions prepared from them were injected into testicles of normal rabbits, positive results (lesions containing numerous active spirochetes) were obtained in all the six animals. This was complicated by the somewhat unexpected fact that a positive result was also obtained with one animal injected intraspinally with physiologic solution of sodium chloride. This renders the interpretation of the results obtained somewhat uncertain. In order to determine whether the effect may not possibly be due to the traumatic shock of the injection, experiments are now in progress in which distilled water and also a number of other substances are being injected intraspinally. The net result is that spirochetes may be induced to penetrate into the central nervous system of rabbits with the aid of an intraspinal injection of normal testicular tissue or (in one case) physiologic solution of sodium chloride.

*Specificity of the Weil-Felix Reaction. H A Kemp H E Wright and Faith Wayne Dallas—p 278

Weil-Felix Reaction—During the past year and a half Kemp and his associates have been doing Weil-Felix tests on serum from cases of typhoid, paratyphoid and undulant fever. Their work has shown that the Weil-Felix reaction may be positive in conditions other than typhus. They recognize the importance of dissociation in the handling of their stock antigens. They are willing to accept the use of an O type antigen because of an added degree of specificity. They do not at this time possess a clear understanding of the mechanism of the Weil-Felix test. Nevertheless they appreciate its great practical value for two reasons: guinea pig inoculation in the diagnosis of typhus is so fraught with difficulties that it is impossible in the large number of cases in which facilities for this maneuver are lacking and in typhus fever the Weil-Felix reaction becomes positive at relatively high titers (1:240-1:320) early in the disease. These titers will increase as

time passes. Increasing titers of agglutination make a non-specific test a specific test—one of diagnostic importance. Agglutinating titers in the Widal reaction or in the quantitative Huddleson, or in tests against known strains of dysentery organisms increase during the course of these illnesses. The same increase will take place in the agglutinating titers of the Weil-Felix test both in typhus and in Rocky Mountain spotted fever (Parker and Davis). Therein lies the specificity of the Weil-Felix reaction: early positive reaction with increasing agglutinating titer.

Hemostasis in Thyroidectomy—To prevent injuries to the laryngeal nerves or parathyroids, hemorrhage and infection, Nordland and Larson recommend and describe extrafascial ligation of the inferior thyroid arteries preliminary to thyroidectomy. By a careful anatomic dissection, structures may be accurately defined and the advantages of hemostasis gained. The usual type of incision for goiter is made and the flaps containing the platysma and superficial fascias are reflected upward and downward. The medial border of the sternocleidomastoid muscle is dissected free in its lower midportion and the margins are retracted outward. Directly underneath the fascia of the prethyroid muscles is exposed and at the margin of the sternomastoid a vertical slit about 3 cm in length is made in the superficial layer of the deep cervical fascia. The outer cut edge of this fascia is retracted laterally and the index finger is carried posteriorly until it is possible to palpate the transverse processes of the cervical vertebrae. The inferior thyroid artery is found running medially at right angles from the carotid artery at the level of the sixth cervical vertebra. A linen suture on a carrier is readily placed about the artery and the vessel ligated by thrusting the carrier around the superior pole, starting from the trachea and proceeding to the lateral margins of the gland. Blunt ligature carriers are far superior to the application of artery forceps. It is advantageous to guide the carrier with the finger in order to include only the amount of tissue desired. Ligation may be made in this manner either doubly or singly without danger to the superior laryngeal nerve. The authors have carried out preliminary ligation of all four arteries to the thyroid in 168 cases and state that with proper preliminary hemostasis the operative field is drier, the incidence of injury to the recurrent laryngeal nerves is definitely decreased, fewer ligatures on bleeding vessels are necessary, postoperative wound drainage is less in amount, and a better cosmetic as well as functional result is uniformly obtained. The particular indication for preliminary ligation of the inferior thyroid arteries exists in the case of recurrent toxic goiters in which secondary operations are especially prone to be complicated by nerve injury, hemorrhage and infection. Improvements in results as well as facilitation of technique have been found to accompany the procedure in this type of case. Nutrition to the parathyroid bodies is not impaired following this type of ligation.

Hyperthyroidism and Pregnancy—Lehman states that in order to protect the patient during the subsequent months of gestation and during labor it is necessary to control the hyperthyroidism. A properly conducted thyroidectomy is much more satisfactory and is attended with less risk than an interruption of pregnancy. Of the authors thirty-three cases five could not be traced; twenty-three patients went to full term and were delivered of healthy offspring, two required cesarean section but bore healthy babies, one was delivered at eight months of a hydrocephalic monster in one the pregnancy was interrupted because she was too weak for the ordeal of labor, and one patient died of cardiac failure one month after lobectomy, from an acute exacerbation of a long standing hyperthyroidism.

*Para-Esophageal Diaphragmatic Hernia N. C. Lake—p. 331

*Electrosurgical Treatment of Minor Anal Conditions W. A. Mein—p. 332

Para-Esophageal Diaphragmatic Hernia—Lake describes an operation for para-esophageal diaphragmatic hernia and reports a case in which the operation was performed. After four years there has been no recurrence of symptoms. With the patient under tracheal ether anesthesia, an epigastric, paramedian laparotomy was performed, the constriction of the stomach, where it passed through the diaphragm, was examined and no evidence of permanent damage to the wall was found. There were no intrasaccular adhesions and the stomach was easily reduced into the abdomen after the admission of air to the sac. The peritoneal sac was passed through the diaphragm immediately to the left of the esophagus and aorta (corresponding to a para-esophageal defect), which was about $2\frac{1}{2}$ inches wide by 5 inches long. The sac could not be inverted into the abdomen, and efficient repair of the aperture from the abdominal aspect appeared unlikely. Therefore the abdominal wound was packed and the patient turned on his right side for thoracotomy. The eighth rib was resected for practically its whole extent through a long incision extending back to the spinous processes. The pleura was opened and the lung was allowed to collapse by reduction of the intratracheal pressure. After protective measures were applied, the lung was retracted upward and the heart somewhat forward. A thin fibrous layer that covered the peritoneal sac was incised and, the greater part of the sac having been removed, the aperture was closed by a ring catgut suture. The muscular defect was closed by the use of tendinomuscular strips cut from the semispinalis muscles at the vertebral end of the incision. Six of these sutures were "darned" over the aperture without strain, the Gallie technic for fascial sutures being used. The esophagus was slightly short, but the level of closure was carried upward as the esophagus was approached. The reflected pleura was sutured over the fascial "raft" and the superficial wound was closed in the usual manner, the pleural cavity being completely emptied of air by raising the intratracheal pressure and so expanding the lung before the last pleural suture was tied. The patient was turned again on his back and the stomach was anchored to the anterior abdominal wall, after the fashion of a Rovsing gastropexy, before the abdomen was closed. Convalescence was uneventful. The patient left the hospital forty days after admission, taking all food without discomfort.

Electrosurgical Treatment of Anal Conditions—For anal fissures Mein uses the monopolar or Oudin current. After anesthesia, a rectal speculum is introduced and the fissure located and "sprayed" with this current. The dehydrated eschar is left in place. From three to four days after the operation, the anus is gently swabbed out with a mild antiseptic. The patient is allowed up on the day after the operation. In anal polyps, perianal anesthesia is administered and the polyp is brought down. If the base is higher than the line of perianal anesthesia, it is injected with a local anesthetic. A pair of curved artery forceps are applied to the base of the pedicle. The polyp distal to the forceps is severed with the cutting current. The electrode is then applied to the point of the forceps and the coagulating current turned on until a zone appears proximal to the forceps. If the base is broad a catgut ligature should be applied. If the polyp is above the line of peritoneal reflection, the ultimate slough will extend beyond the coagulated area visible at the time of operation. If too heavy or too prolonged a current is used, a perforation into the peritoneal cavity may result. The patient can be discharged in a week or ten days. In anal fistulas, local anesthesia is administered as usual. A soft phosphor bronze wire about 3 inches in length is used as the positive electrode. The wire is introduced down the sinus in its entire length until a finger in the

rectum feels the end of the wire just under the rectal mucous membrane. The wire is withdrawn about one-fourth inch and a medium coagulation current is passed until the skin shows signs of coagulation. With the current still on, the wire is withdrawn and a dry dressing is applied. The patient is allowed up on the following day. In hemorrhoids, after anesthesia, some gauze is rolled into a pear-shaped mass and inserted up the anus beyond the hemorrhoid bearing area. Traction is made on it. A needle, bent to form a small arc of a large circle, is used as the electrode. Each hemorrhoid is punctured at the distal end, and the electrode is inserted for a distance of about one-half inch. The coagulation current is turned on until an area of coagulation appears at the entrance. About the same time the hemorrhoid proceeds to "boil." The electrode is removed with the current still on. In cases of thrombosed hemorrhoids, the ordinary straight needle is used. The hemorrhoid is opened with a cutting current and the clot is evacuated by sponging. A ball electrode is then used, and the interior of the hemorrhoid is thoroughly sprayed with the coagulating current. Any anal tags are excised with the cutting current. The wound is dressed with a pyramidal dressing. The patients are permitted to get up on the fifth day and discharged on the seventh day. Postoperatively, the bowels are not allowed to act up to seven days. This may vary, the criterion being the tolerance of the patient. On the sixth night cascara is given and, half an hour before the bowels act on the following day, from 4 to 6 ounces of warm olive oil is slowly injected into the rectum and retained.

Typhoid-Paratyphoid Agglutinins—The results of Giglioli confirm those of Gardner that typhoid-paratyphoid inoculation gives rise to production of somatic agglutinins. This reaction is marked in the first few weeks following vaccination but it is always limited to low and medium dilutions, the highest titer at which a positive result was recorded in the author's series of cases with an O antigen was 1:320. In actual typhoid infection, H agglutinins usually occur in much higher titers than the corresponding O agglutinins, but even so the O titers found in typhoid patients are generally much higher than the O titers found in vaccinated subjects, especially after more than two months has elapsed from the date of vaccination. Smith, in his recent work on cases of typhoid and paratyphoid B, has shown that a single test may not be sufficient for the demonstration of somatic agglutinins. Repeated tests invariably revealed their existence, usually in considerable titers (from 1:100 to 1:400). In the author's experience with typhoid (four cases) and paratyphoid C (twelve cases), O agglutinins have been found constantly after the first week of the disease in dilutions from 1:80 to 1:2,560, usually appearing at a somewhat earlier date in the course of the disease than the corresponding H agglutinins. The presence of O agglutinins in the serums of vaccinated subjects does not destroy the utility of qualitative receptor analysis as a means for the serologic diagnosis of typhoid in vaccinated

subjects, but it is necessary to make this a quantitative as well as a qualitative test by establishing the end titer of agglutination for each antigen. The test should be repeated after an interval of a week or more in negative or doubtful cases. In the diagnosis of typhoid in vaccinated subjects, one should not expect much from serologic methods during the first three months following inoculation, but after this period has elapsed the finding of O agglutinins in a high dilution suggests active infection, negative observations, on the other hand, have little value unless confirmed by repeated tests, carried out at intervals of five or six days.

Media for Differentiation of *Bacillus Coli* and *Bacillus Lactis-Aerogenes*—Wilson describes an agar medium that enables one to make a direct estimation of the numbers of coliform bacilli in a water or milk sample. An enrichment medium for *Bacillus lactis-aerogenes* is one containing in every 100 cc of peptone water 0.5 Gm of sodium citrate, 0.25 Gm of soluble starch and 1 cc of a 1 per cent watery solution of neutral red. Enrichment mediums for *B. coli* are (1) lactose peptone water containing in every 100 cc 1 Gm of anhydrous sodium sulphate and 2 cc. of a 1 per cent solution of rosolic acid in absolute alcohol, and (2) lactose peptone water containing in every 100 cc. 2 cc of a 40 per cent solution of methenamine in water. A medium consisting of 100 cc of water, 10 Gm of peptone, 1.25 Gm of soluble starch sterilized at 115 C for fifteen minutes and 5 cc of Andrade's indicator was found useful in the differentiation of *B. coli* and *B. lactis-aerogenes*. Of twenty-three strains of *B. coli* tested, twenty-one gave entirely negative results, while two, after an incubation period of a few days, produced an acid reaction. Of these two, one was isolated from the urine in a case of cystitis and one from feces, and both appeared to be pure cultures. Of forty-four strains of *B. lactis aerogenes* tested, thirty-eight produced acid and gas and six were negative. The addition of starch to the citrate neutral red peptone water medium proved of advantage in practice. In a medium containing 1000 cc of water 10 Gm. of peptone 1.25 Gm. of soluble starch, 5 Gm of sodium citrate and 10 cc. of a 1 per cent solution of neutral red, twenty-nine strains of *B. coli* failed to grow, whereas forty-eight strains of *B. lactis-aerogenes* gave good growth, resulting often in the bleaching of the medium.

***Wuchereria Bancrofti* Infections**—O'Connor and Hulse excised the lymph nodes in two cases diagnosed as filarial, with a view to recovering adult filarial worms. Both operations were performed before midday and it was predicted as the result of previous observations that, if living *Wuchereria bancrofti* females were present, parturition would not have taken place but would be imminent or just beginning. The prediction proved to be correct in both cases. In the first case the glands were excised at 11.30 a.m. and microfilariae were found in the vagina and in small numbers in the lymph canals close to the vulva. In the second case while microfilariae

were also found in the vagina, no embryos had reached the exterior of the parent worm before operation. In both cases, apparently healthy microfilariae and microfilariae and eggs in various stages of degeneration were found in the afferent radicles and cortical sinuses of lymph nodes. In a separate group of glands in the second case, healthy and degenerating microfilariae but no eggs were found in similar situations. This confirms O'Connor's previous observations that microfilariae reaching a lymph node along the lymphatic vessel containing the parent female may be destroyed in the gland. Apparently, destruction of microfilariae and eggs in the glands may take place by disintegration and absorption as well as by calcification. How eggs in addition to microfilariae may reach a lymph node is not clear, but it seems possible that, independent of abortion, a few eggs may pass to the exterior of the worm following the stream of microfilariae through the vagina at the end of parturition. If the parent worm is at some distance from the gland, it is conceivable that the nearly developed eggs will have completed development in the lymphatic canals and, having stretched the chorionic membrane, be transformed into completely developed microfilariae by the time they reach the gland. The numbers of microfilariae circulating in the blood at night in the second case were not immediately diminished after operation but were at first increased and later decreased. The authors suggest that the initial increase in numbers may have been due to the removal of the gland filters when the embryos had been destroyed, so that the parasites would reach the circulation in increasing numbers through the walls of the lymph nodes, a possibility that has already been demonstrated by O'Connor. Subsequently, owing to the obstruction of the lymphatic vessel by gland excision, stasis of lymph would probably occur followed by lymph thrombosis occasioning death of the parent worm or worms. A diminution in the number of microfilariae in the night blood would naturally ensue. The microfilariae still found in the blood at night probably come from other filariae beyond the scope of the two operations. In both cases, microfilariae and eggs were found in the cortical sinuses and substance of lymph nodes, where they were undergoing degeneration.

Meningitis Due to Hemophilic Organisms—Carter and Macleod present three fatal cases of meningitis due to so-called hemophilic organisms. The organisms differ in several respects morphologically, culturally and biologically from the classic coccobacillus of Pfeiffer, though some relationship probably exists. The identity of Pfeiffer's bacillus with certain influenza-like organisms occurring in so-called influenza meningitis, leptothrix meningitis and septicemic cerebrospinal meningitis has been doubted by several writers, as Cohen, Henry, Braxton Hicks and Dible. The samples of cerebrospinal fluid from the three cases were all similar in character, moderately turbid with light purulent deposits. Microscopically, each contained large numbers of leukocytes, most of which were polymorphonuclear in type, and many pleomorphic gram negative bacilli.

Value of Queckenstedt-Stookey's Test in Nervous Diseases—Roger and Alliez studied the manometric curves obtained by Stookey's method of eliciting and registering the Queckenstedt sign in many diseases of the central nervous system. In normal persons the pressure of the cerebrospinal fluid rises from 30 to 40 cc in from ten to twelve seconds after compression of the jugular vein. Its descent does not exceed fifteen seconds. In pathologic conditions there may be complete block of the subarachnoid passages, in which case compression of the jugular vein produces no rise of pressure or only a few centimeters. Partial block exists when the pressure of the cerebrospinal fluid rises only 15 cc in twenty seconds and requires more than twenty-five seconds to descend to its initial level. Cases in which intermediate curves are obtained must be considered doubtful. In spinal compression the block is almost always complete, whether the compression is due to Pott's disease, cancer of the spine, pachymeningitis or similar conditions, it may be partial in the early stage of a spinal tumor or a recent, slight compression. Block probably depends not only on the volume of the tumor but on the arachnoid reaction associated with it. In a tumor without congestive reaction, block may be absent. Partial block is much more frequent in arachnoiditis than in compression from any other reason. Chronic myelitis and multiple sclerosis never produce a complete block, but the rise of pressure of the cerebrospinal fluid is usually retarded, indicating a partial block. Amyotrophic lateral sclerosis and tabes produce only insignificant modifications of the manometric curve. In syringomyelitis the graphs may be normal or depict total or partial block, probably depending on the degree of gliosis and hypertrophy, in radiculitis, on the other hand, the graph is always normal. In spinal diseases the complete block has an absolute value, but partial block must be interpreted in relation to other symptoms. A normal manometric curve does not rule out compression, since certain subarachnoid strictures have little influence on the cerebrospinal fluid. The Queckenstedt-Stookey test usually confirms the roentgenographic results but does not furnish such accurate diagnostic information. In encephalic disease the test must be employed cautiously, as it is not without danger in intracranial hypertension. It may have important therapeutic consequences, as the demonstration of an occipital block is an indication for ventricular puncture in cerebrospinal meningitis as well as in cranial trauma. In the latter case it is essential to know whether a complete or partial block exists before deciding on surgical procedure. In cerebral tumors the high degree of hypertension makes the use of Stookey's method difficult. The test is not modified in epilepsy, Parkinson's disease and dementia paralytica. The test is a valuable supplement to the study of the spinal fluid and to spinal roentgenography in spinal meningeal and encephalic diseases.

Pseudotumoral Syphilis of Spine—Launay and Poumeau-Delille discuss the inconstant action of antisyphilitic therapy in pseudotumoral syphilis of the spine, the term applied by them to syphilitic pachymeningitis, which is generally localized in the lumbar region and which may or may not be associated with syphilitic myelitis. They think that the existence of the myelitis and its mode of reaction to treatment are prime factors in determining this difference in the response of the patient. They report a case that illustrates the dissociated action of treatment in combined meningeal and spinal disease of syphilitic origin. The patient had a syphilitic paraplegia associated with a syndrome of incomplete compression of the dorsal region. This syndrome consisted of intercostal pains of the radicular type, relative albuminocytologic dissociation

and partial block (revealed by the Queckenstedt-Stookey test). Under the influence of antisyphilitic treatment the radicular pains disappeared, the circulation of the cerebrospinal fluid returned to normal and the hyperalbuminosis of the spinal fluid disappeared. From this the authors conclude that the syndrome of compression was probably due to arachnoiditis of the dorsal region which receded following antisyphilitic treatment. The severe paraplegia persisted undiminished despite continued treatment. The unique motor symptoms that persisted must have been due to the subjacent syphilitic spinal sclerosis, which is not amenable to treatment.

Treatment of Angina by Certain Amino Acids P Halbron, J Tenormand and P Durrigues—p 1585

*Study of Circulatory System and Cardiac Function by Registration of Arterial Pressure R Giroux and G Boulitte—p 1586

*Experimental Colibacillary Catatonia and Colibacillary Psychoses H Baruk—p 1588

Study of Arterial Pressure—Giroux and Boulitte describe a new instrument perfected by the latter, which registers the absolute value of the arterial pressure at each moment of the cardiac contraction in the form of a continuous curve traced on a photographic film. This curve registers the maximum and minimum tensions and the average tension. The method can be applied to different arteries, permitting a precise study of the circulatory system of the normal and pathologic person. The essential part of the apparatus is a new type of manometric and optic oscillograph, which is linked to the needle puncturing the artery by a tube containing an anticoagulant. The amplification is considerable (about 20,000) because the displacements are extremely weak and the movements of the anticoagulating fluid through the lumen of the needle are nil, as are the effects of the viscosity, since the blood does not penetrate into the needle. The movements of the manometric oscillograph are photographed on a film moving at constant speed and marked every one twenty-fifth second by a chronograph, the arterial pressure (in centimeters of mercury) is thus marked on the film along longitudinal lines. Several tracings taken in normal persons and patients with various kinds of heart disease are reproduced but the authors consider it too early to draw general conclusions. The curves of the arterial pressure make it possible not only to study the condition of the arterial system but also to discover modifications throwing light on the functional capacity of the myocardium.

Experimental Colibacillary Catatonia—For several years, Baruk's attention has been drawn to the role of colibacillary infection in the genesis of certain psychoses. He has now succeeded in demonstrating experimentally the role of colibacillary toxin in the genesis of catatonia. By subcutaneous injections of a neurotropic colibacillary toxin (obtained from Vincent) he produced in animals all the signs of catatonia and even symptoms such as negativism and stereotypy. The experimental colibacillary catatonia is especially pronounced in animals with a highly organized nervous system, including cats and some other mammals, and much less perfect in birds. In other vertebrates one can no longer speak of catalepsy or catatonia but only of a torpid state. The fundamental mechanism of colibacillary catatonia appears to reside in a special somnolent action: the colibacillary toxin produces a torpor which, however, even in lower animals, is accompanied by special psychic reactions, such as agitation and emotional and aggressive reaction. These experimental ideas are in harmony with the important role of cataleptic sleep and onirism in human catatonia. The author notes that the results were often inconstant, varying with the age and virulence of the toxin and resulting also from the difficulty of exact dosage of the toxin and of watching the animals continuously for hours or days to detect the sometimes transitory appearance of catatonic states.

*Mode of Action of Phrenectomy Bonafe—p 1604

Mode of Action of Phrenectomy—Bonafe calls attention to the importance of distinguishing between the purely

mechanical action of phrenicectomy and the modification of the pulmonary innervation resulting from the unavoidable extirpation of fibers of the sympathetic during phrenicectomy. The rapid healing of severe ulcerating lesions after phrenicectomy is a result of vasomotor action due to the partial sympathectomy, in his opinion, and the congestive attacks, sometimes developing at the base of the lung, the asthmatic and the gastralgic attacks may be due to a vagosympathetic disturbance also resulting from the sympathectomy. A case observed by the author permits the dissociation of the mechanical effects of phrenicectomy and the accessory nervous effects. In a patient with fibrocaceous tuberculosis the accidental excision of a cervical nerve other than the phrenic (by another surgeon) resulted in the rapid disappearance of the cough and auscultatory signs, although no modification of the movement of the diaphragm and no ascent had occurred. Excision of the intact phrenic nerve in a second intervention was followed by the customary immobilization and ascent of the hemidiaphragm. The absence of sensory and motor disturbances after the first intervention indicates that the extirpated nerve was an important anastomotic branch of the phrenic with the sympathetic. Probably an unusual anatomic condition permitted the dissociation of the mechanical effects of phrenicectomy and the purely nervous effects, heretofore considered accessory. Among the latter is the postoperative dyspnea. It is usually out of proportion to the ascent of the diaphragm and the extent of the lesions, in this case it was observed after the first intervention. The complex mode of action of phrenicectomy that results from the more or less extensive obligatory sympathectomy demands further study.

Amount of Lactic Acid in Blood in Experimental Occlusion of Common Bile Duct M Titone—p 618

Periduodenal Hernias—Papa states that 90 per cent of cases of internal hernia are periduodenal. Predisposing causes are abnormal size and depth of the fossas and narrowness of the outlet and abnormality in the position of the vascular arch that surrounds it, proximity of the inferior mesenteric vein to the fold circumscribing the opening, and minor resistance of the peritoneum or greater laxity of the retroperitoneal connective tissue in patients constantly losing weight. The author maintains that the periduodenal fossa forms a recess capable of accommodating an intestinal loop and comparable to the peritoneal inguinal pouch and its remains in oblique inguinal hernia. From this point of view all periduodenal hernias may be considered congenital, despite the intervention of acquired factors capable of gradually distending the small pre-existing pouch and transforming it into a true hernial sac. According to most authors, this would be formed at the expense of the primary leaf at the right of the root of the mesentery, between the mesocolic vessels anteriorly and the fusion of the left leaf with the posterior parietal peritoneum. Therefore the anterior wall of the sac would be formed by two peritoneal leaves while posteriorly the peritoneum would cover the herniated viscera. It is certain that the denomination of retroperitoneal hernias is incorrect. The contents of periduodenal hernias are almost always the small intestine and its mesentery. The author distinguishes three groups: in the first the symptoms are those of ileus due to strangulation. Hernia may be suspected if there is evidence of an abdominal tumor in the right or left hypochondriac areas in the sac develops within the transverse mesocolon and more especially if attacks of partial occlusion occur in which the ileus represents the final stage. The author observed that the hernia can be seen in the iliac fossa as it becomes larger. In the second group there are symptoms of gradually increasing intestinal obstruction accompanied by acute attacks of partial obstruction. The alteration in patency of the intestinal tract result in diarrhea abdominal pains and colics and nausea accompanied by alimentary and biliary vomiting. Abdominal tumor when present may exhibit changes in size depending on intestinal function. Development of hemorrhoids and pres-

ence of blood in the feces are found in connection with circulatory disturbances of the lower mesenteric vessels. Diagnosis cannot be definitely made, but it can be helped by roentgenography. In the third group, objective examination reveals little or at most presents a diffuse abdominal distention. The patients suffer from dyspepsia, pains a feeling of heaviness lasting several hours after eating, epigastric cramps, nausea lack of appetite, belching and constipation. These symptoms might well be indicative of gastrectasia, dyspepsia and enteroptosis, as well as gastric and duodenal ulcer. In these cases roentgenologic examination may give an exact diagnosis. A characteristic of this entity, also found in a patient of the author, is the displacement of all the loops of the small intestine high up and to the left, leaving the right and lower quadrant void of barium shadows on roentgen examination. In the author's case the intestine displaced the large curvature of the stomach medially. Roentgenologic evidence suggestive of periduodenal hernia would be the presence of clear zones at definite distances apart above the small curvature and distinct from the gastric shadow.

Semana Médica, Buenos Aires

40 869 972 (Sept 28) 1933 Partial Index

Localization and Development of Melanin Cells in Human Cerebellum J Aranovich—p 927
Abdominothoracic Deflection Caused by Nonneoplastic Pulmonary Disease Case H Basabe—p 933

Significance of Deep S Wave in Lead I—On the basis of an examination of 8,000 electrocardiograms, Padilla and Cossio believe that the presence of a deep S wave in lead I of the electrocardiogram is of diagnostic value indicating organic diseases of the heart. They regard the S wave of the electrocardiogram as deep when its amplitude exceeds from 25 to 30 per cent the greatest amplitude of the initial ventricular complex in any of the three leads. A deep S wave deviated to the right side of the electrical axis indicates a preponderance of the right ventricle, caused usually by a disease of the mitral valve and to a lesser degree by a congenital heart disease or by a pathologic condition of the pulmonary artery. A deep S wave nondeviated to the right side of the electrical axis indicates in 95 per cent of the cases the presence of a myocardial disease, especially of the mitral valves, or pathologic changes in the coronary arteries, such as those observed in infarct of the myocardium and in angina pectoris. The coexistence of a deep S wave and of a deep Q wave is frequent because the two waves are the expressions of the same electrical phenomenon. A deep S wave represents the final phase of the QRS complex seen in lead I, while a deep Q wave represents the initial phase of the same complex as seen in lead III.

Treatment of Abortion—Puntel reports the results of the management of abortion in a group of 2,219 patients who were treated in a gynecologic clinic during a period of ten years. In this group 147 women were treated for either evitable or inevitable initial abortion. Pregnancy continued in 108, 4 had an incomplete abortion and 35 had a complete abortion. Forty-five women were admitted to the hospital after a complete abortion. These were dismissed after abstention treatment. A group of 2,360 women were admitted to the hospital after a noninfected incomplete abortion. The 2,110 patients in this group who were treated by curettage immediately after their entering the hospital were dismissed after a week's stay in the hospital. The progression of severe anemia caused by the intense hemorrhages in 407 patients in this group was controlled by checking the hemorrhages. A group of 324 patients were admitted with infected abortion without complications. This group is 10.8 per cent of the total number of abortions that were treated. In this group the 255 patients who were treated by curettage immediately after admission were dismissed in good condition sooner than those treated by the abstention treatment. A group of forty-three patients were admitted with infected abortion with complications that is with lesions of

the adnexa or of the parametrium. In this group, eighteen received emergency treatment with instrumental curettage. Only two of the eighteen patients survived the infection and their stay in the hospital was lengthened for several weeks. The rest of the patients in the group of forty-three with infected complicated abortion were treated by abstention and were dismissed in good condition sooner than those who survived among the group that had surgical intervention.

Osmotherapy in Treatment of Brain Compression—Buchka states that the dehydration method of treatment of increased intracranial pressure, introduced by Weed and McKibben and widely adopted in the United States, was not applied in Germany until recently. The purely mechanical explanation of the relation of brain compression to increased blood pressure has given way to the modern theory of irritation of the vasomotor centers as the cause. The author has used the dehydration method in Schmiedens clinic for the last three years in instances of injury to the skull and as a preoperative and postoperative measure in tumors of the brain. This paper is concerned with the results obtained in thirty-six cases of injury to the skull in nineteen of which a fracture of the skull was present. The author has come to discard sodium chloride or magnesium sulphate because of unpleasant by-effects. Since 1931 he has used, exclusively, a 50 per cent solution of dextrose intravenously in doses ranging from 50 to 200 cc. The injection is given slowly, occupying from ten to twelve minutes. No untoward effect, such as rapid fall in the blood pressure, was noted. When rising intracranial pressure is due to a depressed fracture or to a subdural hematoma the only rational treatment is the lifting of the depressed fracture or the ligation of the spurting vessel. Osmotherapy is indicated in cases in which the local symptoms are largely absent and the general symptoms predominate. Of the thirty-six patients treated by osmotherapy, seventeen were symptom free at the end of the treatment and eleven had only slight symptoms. Two died shortly after injury of severe complications, and in six the end-result could not be estimated because of such conditions as epilepsy or psychosis. Histories of four patients are given in whom intravenous injections of dextrose promptly relieved symptoms persisting from two to three weeks after the injury. The author expresses the belief that in cases with difficult localization and predominant general symptoms the method of osmotherapy will replace that of the operation of subtemporal decompression.

- Multiple Tumor Like Skin Nodules of Unknown Origin P. Frank —p 1467
 *Fever Therapy of Female Gonorrhea Experiences in 163 Cases H. Feilchenfeld —p 1471

Fever Therapy of Female Gonorrhea—Feilchenfeld employed fever therapy in 163 women with gonorrhea. A bacteriogenic protein preparation was injected intravenously. The aim was to produce a fever of about 40 C (104 F). The total number of injections was from five to six. In patients who, in the course of these injections, reacted with fever of less than 38.9 C (102 F) the therapeutic result was doubtful, unless they still reacted after the fifth or sixth attack. In some cases favorable effects were produced after the first injection. The author advises against a too large number of injections. He generally began with the injection of 0.1 cc

and increased the dose by 0.1 cc each time until 0.6 cc had been reached. Intervals of from four to five days between injections were found most advantageous, since a too rapid succession of injections (intervals of one or two days) may accustom the organism so that the febrile reaction is no longer sufficiently intense. Of the total number of 163 patients, 117 (71.7 per cent) improved and became free from gonococci as the result of the fever therapy. The treatment was effective particularly in refractory gonorrhea of the cervix, and it counteracted inflammatory disturbances of the adnexa. However, open gonorrhea of the mucous membrane of the urethra and of the anus and gonorrhea of the vulvovaginal glands was not influenced by the fever therapy. The author thinks that the therapeutic effect is due primarily to some alteration of the tissues. He thinks that fever therapy is most effective in gonorrhea of the cervix which does not yield to local measures. But since severe complications cannot always be avoided in the course of fever therapy, he advises that it be used only as a last resort.

Electrocardiographic Observations in Acute Myocarditis—Quincke combines the description of the course of a myocarditis with a description of the most frequent disturbances in the conduction system of the heart. He shows how the electrocardiographic record of a new myocardial lesion gives a clear insight into the steadily changing disturbances of the cardiac function. In the course of a myocarditis lasting two weeks, all forms of conduction disturbances may appear and disappear again: constant and increasing retardation of the conduction, partial auriculoventricular block, bundle branch block and arborization block.

Iodine Combining Capacity of Blood—Hinsberg and Holland call attention to the important role of the unsaturated fatty acids in intermediate metabolism, in the processes of food resorption, and in the regulation of the cellular function, particularly of diffusion. The unsaturated fatty acids detected so far in the organism are oleic, linoleic, linolenic, arachidic and clupanodonic acids. In order to avoid complications, the

authors determined only the total amount of unsaturated fatty acid. For the extraction they employed Bloor's method, and the bromine additive capacity was determined according to Winkler, but, instead of the iodine number of the extracted fat, they determined the iodine combining capacity, that is, the quantity of iodine bound by the fatty acids from 100 cc. of blood. This quantity is more constant than the iodine number, because it is independent of the total quantity of the lipoids. In the formation of the unsaturated fatty acids the functions of the liver, kidney, intestine, biliary tract, pancreas and thyroid are involved. The authors cite experiments demonstrating that a slight lack of oxygen produces an increase in the unsaturated fatty acids of the blood, while great deficiency of oxygen effects a reduction. The important part played by unsaturated fatty acids in intermediate metabolism is borne out by experiments on pancreatectomized dogs which survived for more than two years without insulin, when lecithin (containing unsaturated fatty acids) was added to their food. This effect could not be produced with saturated fatty acids. The authors determined the quantities of the unsaturated fatty acids in healthy persons and in patients suffering from various disorders. As a rule the iodine combining capacity was increased noticeably in diseases of the liver. Patients having pernicious anemia likewise showed values greater than normal, but a gradual and steady reduction set in under the influence of liver therapy, while discontinuation of the liver therapy again was followed by an increase. The hyperglycemia of diabetic patients could be considerably reduced by lecithin (prepared from egg yolks), and the lecithin was the more effective, the higher its iodine combining capacity.

Action of Milk Injections in Gonococcal Infections.—The therapeutic efficacy of milk injections in gonorrhea and particularly in the metastatic eye disorders induced Buschke and Casper to study the action mechanism of milk injections in animal experiments. Studies on white rats disclosed that prophylactic intraperitoneal injections of milk protect the majority of the animals against a gonococcal infection induced with ten times the lethal dose. This could perhaps be interpreted as indicating an active immunity conferred on the animals by the milk injections. However, the authors point out that milk therapy has no influence on urethral gonorrhea, while it is highly effective in gonorrheal conjunctivitis, and that specific gonococcus vaccines do not influence the metastatic eye diseases of gonorrhea. Thus the action of milk cannot be considered due to the production of a specific immunity. The authors assume that the gonococcus produces certain toxins and that the milk checks the formation of toxin in the organism. By influencing the reticulo endothelial system, it stimulates the leukocytes to phagocytosis and to the formation of protective substances.

Treatment of Sterility.—Bentlin maintains that the man is at fault in more than a third of sterile marriages and that this aspect of sterility should be thoroughly investigated before the treatment of the woman is begun. Sterility may exist in case of apparently normal genitalia, because functional disturbances of the ovaries of the secretory organs or of extra-genital organs and constitutional psychic nervous climatic and nutritional influences may eventually cause sterility. Moreover the manner in which the sexual act is performed may be at

fault. The absence of orgasm and of sexual feeling represent important factors. Vaginismus, due to spasticity of the musculature of the pelvic floor, the result of fear, generally can be counteracted by proper explanations. The woman should be told that the vagina can be opened by abdominal muscular pressure. The author describes measures for the prevention of too rapid discharge of the semen from the vagina, such as a prolonged rest and a slight elevation of the pelvis following coitus. He discusses the advisability of dilatation of the cervical canal, insufflation of the uterine tubes, improvement of the woman's general condition, temporary sexual abstinence, treatment with ovarian preparations and artificial impregnation. Myomas of the uterus are less frequently a cause of sterility than is sometimes believed. Their removal is necessary only in case they are of submucous and cervical location, in case they grow rapidly and are multiple, and when they cause distortion of the uterine cavity.

Autocomplement Titer and Allergy.—Deutsch and Weiss point out that new serologic methods have stimulated interest in the determination of the normal antibody content of the serum and particularly of the autocomplement titer, but that the nature of the complement is not yet completely understood, for by some it is considered a structural constituent of the serum, by some a protein body and by others a ferment, while at present it is generally considered a functional condition of the serum rather than a distinct body. At any rate, it is certain that the complement in the serum is a normal biologic condition, and the disappearance of the complement in anaphylaxis and the changes it undergoes in various conditions are therefore of great interest. The authors emphasize that the height of the complement titer is largely dependent on the method by which it is determined, for instance, it is important how much time has elapsed since the withdrawal of the blood, in what manner it was stored in the meantime, and at what temperature the test is made. They made their tests four hours after the withdrawal of the serum. The titer is expressed by the quantity of serum that effects complete lysis. Titer values of less than 0.05 cc indicate an increase in the complement, and values in excess of 0.08 cc indicate a reduction in the complement. Inhibition of lysis when 0.2 cc or more of serum is added indicates practically a complete absence of the complement. The authors call attention to reports in the literature, in which the theory is defended that certain forms of rheumatism are not infections but present an allergic condition, which in turn is due to a sensibilization originating in a focus of infection. In the allergic complex, conditions such as polyarthritis, endocarditis and glomerular nephritis present a phase that is accompanied by a disappearance of the complement. There are a number of diseases of varying etiology in which allergic reactions exist, but only if the definition of allergy is taken in the wider sense as given by von Bergmann does it become understandable that a disappearance of the complement exists in such different disorders as atrophy of the liver and allergy, for in both of these processes the protein metabolism is seriously impaired. The authors illustrate the significance of the disappearance of the complement with a case history. Von Bergmann's definition of allergic disorders stresses the significance of endogenous allergens. This author thinks that the intermediate autoinactivation of the sensitized organism presents an important factor in the problem as to why inflammations flare up and subside, whether bacteria play a part in them or not. Observations on the phenomenon of the autocomplement indicate how the knowledge of an allergic inflammation can be utilized in the clinic.

Ménière's Vertigo in Polycythemia.—A report in the recent literature about the concurrence of Ménière's vertigo with polycythemia and the disappearance of Ménière's vertigo following the successful treatment of the polycythemia with a high fat diet induces Bieling to report a case of his own observation. The patient a man aged 38, had frequent attacks of vertigo and complained of ringing in the ears. Examination of the blood revealed an erythrocyte count of over six million, a hemoglobin content of 107 and a color index of 0.85. Treatment with a preparation of spleen was instituted in order to counteract the polycythemia. The result of this treatment was that the blood picture became normal and the Ménière vertigo disappeared.

Intrathoracic and Intra-Abdominal Quartz Lamp Irradiation—Fervers calls attention to the fact that in recent years efforts have been made to apply ultraviolet rays to parts of the body ordinarily not reached by rays the larynx, the vagina and even the inside of the bladder. The peritoneum has been irradiated with ultraviolet rays in the course of operations. The author devised a new method comparable to this irradiation during a surgical intervention. By puncture, the abdominal and pleural cavities can be subjected to the therapeutic action of ultraviolet rays. The instrumentarium consists of a rod-shaped cold quartz lamp. The shaft of the lamp is silver plated and only 5 cm at the end is left uncovered, so that the rays are emitted only here. The rays are produced by a glowing discharge in the burner, and a transformer keeps the burner cold in the open as well as in the body cavities, so that the temperature of the body is not surpassed. For special purposes the linear burner may be surrounded by a tightly fitting cover of blue or dark ultraviolet glass. The lamp can be connected with any lighting circuit. The intrathoracic and intra-abdominal treatments require pneumothorax and pneumoperitoneum, respectively. The irradiation generally lasts three minutes, after which the small opening is closed with a cutaneous suture or with a clamp.

Errors in Diagnosis of Sarcoma—Ilichenko states that there were 187 cases of sarcoma of the extremities and of the trunk treated between 1921 and 1931 at the Institute for the Treatment of Tumors in Moscow. In 71 of these a wrong diagnosis was made. 66 were diagnosed incorrectly at various medical institutions prior to admission to the institute, 4 were diagnosed incorrectly at the institute but were recognized later and one received a wrong diagnosis at the institute. The most frequent diagnostic errors included such conditions as sciatica, periostitis, tuberculosis, osteomyelitis, syphilis and the various benign tumors. The hip and the leg furnished the greatest number of wrong diagnoses. The first symptom of sarcoma in 50 per cent of wrong diagnoses was pain, in 31 per cent the tumor, and in 6 per cent, in addition to other early symptoms, elevation of temperature. The following factors contributed to the mistakes in the differential diagnosis: (1) the presence of early symptoms of sarcoma, such as pain and rise in temperature, in a number of conditions of nonblastomatous character, (2) inherent faults in such diagnostic means as roentgen examination or biopsy, or their employment at the wrong moment, (3) diagnosis made on the basis of a single method of investigation, such as roentgen examination or biopsy, without a consideration of the general clinical picture, and (4) deep localization of the growth. The author suggests that the diagnosis of sarcoma should be thought of in the presence of long continued pain in an extremity not yielding to treat-

ment even in the absence of a clinically demonstrable tumor. In his material 80 per cent of sarcomas were mistaken for inflammatory lesions, while in 20 per cent the error was in the reverse order, the inflammatory lesions being diagnosed as sarcoma. Because of similarity in the early symptoms of inflammatory lesions and of sarcoma, physical therapeutic measures particularly massage, should be employed with great caution. In the presence of a tumor the nature of which has not been determined, such therapy is inadvisable.

Finska Lakaresallskapetets Handlingar, Helsingfors

75 829 929 (Sept) 1933

- *Hepatogenic Hemorrhagic Diathesis E A von Willebrand —p 829

 *Organic Heart Diseases in Thrombo-Angitis Obliterans and in Raynaud's Syndrome M C Ehrstrom —p 892

Hepatogenic Hemorrhagic Diathesis—Von Willebrand states that his first two cases present a picture in accord with Frank's "hypoleukia splenicohepatica," a syndrome occasionally seen in connection with grave liver insufficiency. He ascribes the origin of the hemorrhages mainly to the pronounced thrombopenia and partly to changes in the blood vessels. In the third case, with seropositive syphilis and aortitis, arsphenamine jaundice and acute atrophy of the liver developed after treatment with neoarsphenamine. The patient had massive hemorrhages with marked jaundice, prolonged bleeding time and delayed retraction of the clot. The pathogenesis of the hemorrhages is chiefly attributed to the disturbance in coagulation, also in part to changes in the blood vessels.

Organic Heart Diseases in Thrombo-Angitis Obliterans—Ehrstrom describes four cases with organic defect in the mitral valve, one combined with thrombo angitis obliterans one with vasomotor neurosis, and two with vasomotor neurosis and organic change in the blood vessels. He asserts that changes in the blood vessels in Raynaud's disease and thrombo angitis obliterans and in septic and some forms of syphilitic angitis may occasionally present similar anatomopathologic pictures. With combined vasomotor symptoms and organic changes in the blood vessels it is extremely difficult to determine which is primary. The combination of organic heart defects, especially mitral defects, with changes in the peripheral vessels makes it probable that the latter occurred secondarily on the basis of pathologic changes of the circulation due to the cardiac defect.

Mummification of Skin—Freudenthal reports two cases of skin gangrene resembling necrosis due to pressure (decubitus), one on the radial side of the arm and the other on the volar surface of the underarm. Both are ascribed to a tightening bandage, properly applied but allowed by the patient to remain without attention for several days and transformed by blood or secretion into a firm hard dry compress which compromised the nutrition of the skin.

- Malignant Case of Lupus Vulgaris Treated with Modified Forms of Arc Light S Lomholt —p 1115
 *Hereditary Multiple Exostoses O Andersen —p 1116

Hereditary Multiple Exostoses—The exostoses in the first case described by Andersen were discovered when the patient, now a man of 25 was 4 years old. In the second case in a girl aged 8 signs of exostoses were noted at the age of 3. The author, like others, suggests the theory that endocrine disorders play a part in the origin of exostoses. Both patients were fat until the age of 2 and have since been thin and unable to gain. About the time of puberty in the first instance some exostoses disappeared and the others stopped growing. Of thirty-seven members in four generations of the family of the second patient, nine have multiple exostoses. Inheritance is thought to depend on a single dominant factor.

THE EFFECT OF DIURETICS IN DIFFERENT TYPES OF EDEMA

MELVIN W BINGER, MD

AND

NORMAN M KEITH, MD

ROCHFESTER, MINN

Blackall,¹ an English physician, endeavored in 1813 to analyze a series of cases all presenting definite signs of dropsy. He showed that dropsy was due to several different causes. During the last nine years we have in a similar manner studied approximately 200 cases of varied types of edema. Our aim is to present the clinical observations and course of the various diseases in much the same fashion as Blackall, but in addition to give the results of certain biologic, chemical and therapeutic studies. The edema was actually controlled in some cases whereas in others the treatment was unsuccessful. Thus, success or failure to rid the patient of edema could be and was, subjected to critical analysis. We hope that the results reported in this paper will lend to the more general and accurate use of suitable diuretics in the treatment of edema, and possibly to the discovery of further helpful therapeutic agents.

CLINICAL GROUPS

In this study 216 cases in which edema was present, comprising eight different types of disease were considered. These were classified according to diagnosis as represented in table 1. As will be observed in table 2, certain outstanding features were observed in each group.

In this study, renal function, as determined by the value for urea in the whole blood (method of Marshall) and by excretion of intravenously injected phenolsulphonphthalein was normal in the majority of cases. As would be expected more severe renal insufficiency was noted in the cases of chronic glomerulonephritis and of myocardial degeneration associated with diffuse arterial disease.

Protein² was found in the urine in large amounts (graded 3 to 4) in all of the cases of lipid nephrosis and in 92 per cent of the cases of chronic glomerulo-

nephritis. In the other groups, usually only a small amount of protein was found in the urine.

The urine of each patient was examined many times to detect the presence of erythrocytes. If in a given case erythrocytes were never found in any examination, erythrocytes were said to be absent in that case. If, in a given case, erythrocytes were sometimes absent and sometimes present, but never in large numbers, the presence of erythrocytes was graded 0 to 1. If, in a given case, erythrocytes were always present and always in considerable numbers, the presence of erythrocytes was graded 2 to 4. The results are given in table 2.

Hyaline casts were present in varying numbers and were present in all cases of chronic lipid nephrosis and in 96 per cent of the cases of chronic glomerulonephritis. They were present in both cases of myxedema and were less frequently observed in the other groups.

Tests of hepatic function were made in some cases of all groups, results are given in table 2. In only fourteen cases of all the groups was the value for serum bilirubin more than 3 mg in each 100 cc, and in only four cases was there distinct jaundice.

The basal metabolic rate was determined in the cases of four groups (table 2). Estimations were made in six cases in each of the groups of myocardial degeneration and cirrhosis of the liver and with one exception all were normal or above normal.

We previously mentioned that there were thirty-nine cases of glomerulonephritis in which there were alterations in the chemistry of the blood similar to those found in lipid nephrosis. Of these thirty-nine cases, in twenty-one the basal metabolic rate was less than minus 10, and in five of the twenty it was less than minus 20. In seventeen cases the rate was within normal limits, and in a single case it was plus 35, which was thought to be due to coexisting hyperthyroidism. Similar results were obtained in the cases of genuine lipid nephrosis in only three was the basal metabolic rate less than minus 10. Our experience would indicate that the low basal metabolic rate in lipid nephrosis found by Eppinger³ and Epstein⁴ occurs only in a certain percentage of cases. The most obvious explanation of the decreased metabolism would be that it was due to undernutrition.

TREATMENT

The treatment consisted of the use of diuretics and of control of diet and of intake of fluid. In 96 per cent of all the cases the diet was controlled and contained protein from 40 to 60 Gm and sodium chloride from 1 to 5 Gm daily. The water component of the food

⁵ During the period the cases were studied the concentration of the blood was considered the most dependable method for estimating renal function. A concentration of more than 45 mg in each 100 cc of whole blood was considered abnormal because averaging normal persons when under a similar regimen to bring about dehydration the value for blood urea rose to 45 mg in each 100 cc.

⁶ Determined by the method of Folin. The reaction was not shown in this article and is not applicable here.

salicylate¹⁰ These all were used singly and in combination The diuretics most frequently selected, as will be noted in table 3, were ammonium chloride, ammonium nitrate and organic preparations of mercury Derivatives of caffeine were used extensively, they were employed in 66 per cent of the cases of myocardial degeneration However, in a number of cases of the different groups in which the values for blood urea were elevated and in which acid salts and organic compounds of mercury were contraindicated, theophylline calcium-calcium salicylate, theobromine and aminophylline were frequently effective As has been demonstrated previously by Keith, Barrier and Whelan,¹¹ the organic compounds of mercury act more energetically as diuretics in combination with the acid salts ammonium chloride and ammonium nitrate, and the substances were employed in this combination in most of the cases of all groups Engel and Epstein¹² also have found that ammonium bromide and decholin may enhance the diuresis caused by mercury Shelling and Tarr¹³ have shown a similar effect with magnesium sulphate injected intramuscularly Calcium chloride was used to a less extent, and chiefly in the cases of chronic glomerulonephritis and chronic lipid nephrosis Ammonium chloride, ammonium nitrate or calcium chloride were given in doses of from 6 to

§ No retention in one case

ingested was limited to from 800 to 1,400 cc daily, in all of the cases of glomerulonephritis, lipid nephrosis, hepatic insufficiency, intra-abdominal malignant conditions, polyserositis, and general edema of indeterminate origin

The same limitation on the water component of the food was applied in 70 per cent of the cases of heart disease and in one of the two cases of myxedema The intake of extra fluid in the form of water and other beverages was limited to 800 cc, so that the total intake of fluid amounted to from 1,600 to 2,200 cc in 75 per cent of all cases

The diuretics most commonly employed were ammonium chloride, ammonium nitrate, calcium chloride, the organic compounds of mercury, mersalyl and merbaphen,⁹ and the derivatives of caffeine theobromine, theocin, aminophylline and theophylline calcium-calcium

14 Larger doses were occasionally given Two patients received 18 Gm of calcium chloride and three patients ammonium nitrate 12 Gm daily

times in combination with organic compounds of mercury. Organic compounds of mercury, in the form of merbaphen or mersalyl, were always given in a small initial dose of 0.5 cc, and if no untoward reactions occurred, 2 cc was given at intervals of three days or more thereafter. Merbaphen was injected beneath the skin, into the muscles and into the veins, but mersalyl only intravenously. As much as 35.5 cc of the organic compounds of mercury was given to one patient.

EFFECT OF TREATMENT

Immediate—On the whole, a summary of the immediate effect of treatment was gratifying (table 4). The average loss of weight varied somewhat in each group studied and was greatest in the cases of myocardial degeneration.

An ineffectual result of treatment was indicated by slight or no diuresis, inability to reduce edema materially, or progressive course of the disease. Such results occurred most often among the cases of intra-abdominal malignancy.

which was observed during treatment followed the administration of organic mercury.

The occurrence of diarrhea usually followed the administration of merbaphen but sometimes followed the administration of mersalyl. This was not persistent and subsided in a day or two after cessation of the administration of organic compounds of mercury.

Methemoglobinemia, as evidenced by cyanosis and the finding of methemoglobin in the blood, was noted only with the administration of ammonium nitrate. In only one case did it seem to be a serious complication.¹⁵

With reactions resulting both in renal insufficiency and in the production of acidosis, a more serious problem presented itself. In eighty-nine of the 216 cases (table 5), increase in the value for blood urea developed during treatment. In thirty-four of the eighty-nine cases, the value for blood urea was more than 45 mg in each 100 cc on admission, in twenty-eight of these the concentration fell to normal before the patients left the hospital. In fifty-three of the eighty-

Toxic Reactions—Untoward reactions both local and general were noted in certain cases of all the groups studied. They are recorded in table 5. One of the toxic reactions, increased renal insufficiency, was evidenced by increase in concentration of blood urea and lowering of the return of phenolsulphonphthalein. Another toxic reaction was acidosis. Local necrosis, stomatitis, gross hematuria and diarrhea could be traced to the administration of organic compounds of mercury. Local necrosis was observed in three cases following injection, intramuscularly or subcutaneously of mersalyl. When given intravenously this did not occur. Local necrosis did not occur in any instance following intramuscular or subcutaneous injection of merbaphen.

Stomatitis, although uncommon, appeared in nine cases following administration of organic compounds of mercury and more frequently following the use of merbaphen than the use of mersalyl. Gross hematuria

in nine cases the value for blood urea returned to normal before dismissal of the patients.

It often has been observed, with the administration of the acid salts ammonium chloride or ammonium nitrate, together with organic compounds of mercury, that there will be marked diuresis, associated with a rise in concentration of blood urea and, especially when ammonium chloride is given a fall in the carbon dioxide combining power of the plasma. Whether the renal insufficiency as shown by the rise in value for blood urea, is due in these cases to the acidosis to the dehydration or to the direct irritative action on the renal epithelium or to a combination of these factors has not been definitely determined. Usually this reaction is seen in cases in which there previously has been renal injury as evidenced by elevated values for urea and low output of phenolsulphonphthalein.

¹⁵ Euseman, C. B. and Keith, N. M. Transient Methemoglobinemia Following Administration of Ammonium Nitrate. *M. Clin. North America* 12: 1487-1496 (May) 1920.

Decreased Alkali Reserve¹⁶—The carbon dioxide combining power of the plasma was usually normal in these cases on admission. The well known acidosis that is known to be produced by acid salts¹⁷ led us to make, after administration of these salts, frequent determinations of the bicarbonate reserve of the plasma

* As determined by the value for blood urea. In the majority of cases the excretion of phenolsulphonphthalein also was determined and was found decreased.

† One case of urticaria like reaction, three cases of toxic dermatitis.

in 109 of the cases in this series (table 6). The intake of food and fluid was controlled in the manner mentioned previously. It was the rule to estimate the value for urea, the chloride and the bicarbonate reserve from the same specimen of blood. This procedure was a test of certain effects of an excess of inorganic acid on the metabolism of patients with edema, it also gave us information as to the relative action of these acid radicals in different diseases, as for example in chronic glomerulonephritis, myocardial degeneration, and cirrhosis of the liver. The total amount of acid-producing salt exhibited before the sample of blood was withdrawn varied from 9 to 412 Gm (the daily amount averaging from 5 to 10 Gm). The chlorides of ammonium and calcium caused a distinct shift in the acid direction much more consistently than ammonium nitrate. This fact we had noted in previous work.¹⁸ So-called chloride acidosis, in which the plasma chloride was almost invariably increased, was produced in fifty-six cases by doses of from 9 to 412 Gm of ammonium chloride or calcium chloride, and in eight of these, all cases of glomerulonephritis, the carbon dioxide combining power of the plasma decreased markedly to 20 volumes per cent or less. On the other hand, ammonium nitrate in amounts of from 28 to 78 Gm produced a moderate fall in the carbon dioxide capacity of the plasma in only four cases. The relative occurrence of acidosis among fifty-eight cases of the different types of edema are given in table 6. Acidosis occurred in a high percentage of cases of glomerulonephritis, indeterminate edema, abdominal malignancy and hepatic

insufficiency, and much less frequently in cases of cardiac disease and lipid nephrosis. Acidosis also seemed more likely to occur in cases in which there was hepatic and myocardial injury, when complicated by renal insufficiency. In three cases of hepatic insufficiency the plasma carbon dioxide combining power fell to less than 30 volumes per cent and serious renal involvement was indicated by concentrations of blood urea of from 72 to 89 mg in each 100 cc. In only one case of this series was the acidosis severe enough to produce respiratory difficulty.¹⁹ In this, a case of glomerulonephritis, following the giving of 25 Gm of ammonium chloride in five days, typical Kussmaul breathing developed, the carbon dioxide combining power of the plasma decreased to 9 volumes per cent, and the value for blood urea rose from 109 to 276 mg in each 100 cc. This patient's acidosis, fortunately, was successfully combated by intravenous injection of sodium bicarbonate. We believe that marked acidosis, such as occurred in this case, can be avoided, since this severe condition has subsequently never developed in any of our cases.

Usually the degree of acidosis present produces no respiratory or other untoward symptoms.¹⁹ In some cases the reduction in plasma carbon dioxide is only slight after continuous giving of large doses of ammonium chloride. This fact suggests that the body may, under these conditions, gradually develop a satisfactory buffer mechanism to this salt. The observations of Keith and Whelan, that the early acidosis may clear and the carbon dioxide combining power of the plasma

TABLE 6—Effect of Acid Salts on Carbon Dioxide Combining Power and Urea of Plasma

* In three cases plasma urea not estimated. Fifty-six patients with acidosis received chloride from 9 to 412 Gm and organic mercury from 0.5 to 21.5 cc. Four patients with acidosis received ammonium nitrate from 28 to 78 Gm and organic mercury from 1 to 10.5 cc.

return to normal and the finding of Denning Dill and Talbott²⁰ of similar changes in the pH of arterial blood, support such a view. In twenty-nine of our cases in which acidosis developed, the concentration of blood urea was normal, whereas in twenty-six there was an associated rise in the value for blood urea ranging from 46 to 130 mg in each 100 cc if we omit the case of severe acidosis mentioned in which the value for blood urea rose to 276 mg in each 100 cc. A marked rise in the value of blood urea, along with acidosis, following administration of ammonium chloride or calcium

16 It is recognized that a shift in acid-base equilibrium toward the acid side may be compensated in the blood plasma and still the pH of the urine be strongly acid. We have arbitrarily decided in this paper to consider acidosis present only when the carbon dioxide combining power of the blood plasma was below 40 volumes per cent. When the carbon dioxide combining power of the plasma was more than 40 volumes per cent compensated acidosis was said to exist when less than 40 volumes per cent the acidosis was said to be uncompensated.

chloride is a definite contraindication to the further use of these substances

In fifty-one cases, or 47 per cent of the 109 cases in which acid salts were given, the carbon dioxide capacity of the plasma was more than 40 volumes per cent at the time of the analysis of blood. In other words, partial or complete compensation for the acidosis had taken place in the plasma. In thirty-four of these fifty-one cases there was no rise in concentration of blood urea, whereas in seventeen cases it was increased from 46 to 95 mg in each 100 cc. Thus, in a small group in which the acidosis is compensated renal insufficiency does occur, but fortunately it is as a rule, of short duration. It is of interest to point out that early clinical observations indicated that acid salts could be given in large doses to patients with anasarca without apparent toxic effect. There is now chemical evidence that this is often a fact. Conversely, certain patients of this series, with persistently small or moderate amounts of edema when given acid salts quickly gave evidence of acidosis and renal impairment.

Organic compounds of mercury were given to many of these patients in doses of from 0.5 to 21.5 cc (from one to eleven injections) during the period of ingestion of acid salts. The injections of mercury did not appear to enhance the acidosis, nor did the presence of moderate acidosis seem to increase the frequency of toxic effects from mercury. In a single case following the giving of 0.5 cc of merbaphen when marked acidosis was present the carbon dioxide combining power had been reduced to 13 volumes per cent by administration of ammonium chloride, and severe stomatitis and convulsions developed. Several days later this patient, while taking ammonium nitrate, did not give evidence of acidosis, and injection of 2 cc of mersalyl caused no rise in the value for blood urea or other abnormal conditions.

The results of this study of acidosis occurring in various types of edema due to administration of acid salts indicate that the acidosis itself only rarely causes serious toxic effects and that these can be reduced to a minimum when the cases are suitably selected and the administration carefully controlled. Acidosis was produced in several cases in which the diuretic response was satisfactory and the subsequent course remarkably good. Such a result was obtained in our first case in which ammonium chloride was administered nine years ago.¹ The patient, a woman, continues to be free from edema and has excellent general health. The dose of chloride should be carefully estimated and its effect on the carbon dioxide combining power and the chloride and urea content of the blood plasma should be observed from time to time. Severe acidosis thus can be avoided. Ammonium nitrate has much less tendency than ammonium chloride to produce acidosis, therefore it can be used in a larger series of cases and especially in those in which administration of chloride might be contraindicated.

Ultimate Course—A follow-up investigation of the 216 patients of all groups showed that 104 or approximately half, returned one or more times for further observation. The usual reasons for returning were for reexamination or because of recurrence of edema. Two patients returned nine times each. Review disclosed the results recorded in table 7.

The highest mortality has been among the cases of intra-abdominal malignancy with 85 per cent deaths, of the patients with hepatic insufficiency 79 per cent died and of those with glomerulonephritis the per-

centage of deaths was 68. Sixty-four per cent of the patients with myocardial degeneration died. Only one patient with nephrosis died, in this case, acute septicaemia developed following tonsillectomy. Neither of the patients with myxedema and only two of the patients of the indeterminate group, died.

COMMENT

The most constant effect of the therapeutic measures employed in this study was the production of marked diuresis in all types of edema. Similar results have been reported in types of edema not included in this paper, as, for example by de Takats²¹ in acute edema caused by thrombophlebitis. The edema frequently disappeared and the patient's subsequent course was satisfactory. This happy result occurred very often in cases of lipoid nephrosis, in the group of cases of indeterminate edema, and in a limited number of cases of myocardial degeneration, cirrhosis of the liver and chronic glomerulonephritis. Other patients, in spite of only temporary decrease in the edema and the necessity of continuous treatment, derived much comfort. However, in many cases in which there was serious cardiac,

renal or hepatic injury, even with subsidence of the edema the usual progressive course of the disease was not altered.

Obvious toxic effects, such as stomatitis, diarrhea and dermatitis, occurred very infrequently. They occurred relatively more often in cases of hepatic insufficiency than in any other single group of cases and usually followed injections of merbaphen. The most frequent toxic effect was definite renal insufficiency, which was present in approximately half the cases. With this renal insufficiency, clinical symptoms of a toxic nature were usually absent. As one would naturally surmise renal insufficiency occurred most frequently in cases of glomerulonephritis, but it also occurred in a considerable number of cases of hepatic disease. Fortunately in the majority of instances it was a temporary dysfunction and the value for blood urea fell to the normal concentration and the excretion of phenolsulphonphthalein rose before dismissal of the patient. On the other hand the renal impairment of 16 per cent of all patients treated was of longer duration and was still present at dismissal. Severe acidosis

21 de Takats (Cza): The Management of Acute Thrombophlebitis. *Ann. N. Y. Acad. Sci.* 100: 3-7 (Jan. 7) 1953.

when caused by ingestion of ammonium chloride or calcium chloride, may be accompanied by marked renal insufficiency. By careful administration of these salts, such an untoward event can be prevented. It is well to point out that in the compensated acidosis that so frequently is present after these acid salts, particularly ammonium nitrate, have been taken, mild renal impairment does sometimes occur but it disappears quickly when the administration of the salt is discontinued. Dehydration resulting from both a low intake of water and a large output of water from continuous diuresis is a possible etiologic factor in the production of this temporary renal insufficiency. In uncomplicated cases of myocardial degeneration, toxic reactions seem less likely to occur than in cases in which there are either renal or hepatic lesions. This finding is in agreement with previous observers.²²

Organic compounds of mercury, administered in large and rapidly repeated doses, are undoubtedly toxic to the kidneys and other organs.²³ When they are employed as advocated in this paper, we have seen surprisingly little evidence of definite toxicity. Mersalyl is the compound of choice. When gross hematuria did take place after an injection, in several instances the patient later tolerated an equal or larger dose without apparent harm. By using the urea clearance test, Pollard²⁴ has shown that merbaphen depresses the capacity of the kidney of the normal person to excrete urea. Page,²⁵ on the other hand, after the administration of organic compounds of mercury, has found no change in results of the urea clearance test in a small group of cases in which arteriosclerotic kidneys and chronic glomerulonephritis were present. Further studies with this test, and with other more sensitive determinations than that of concentration of blood urea and excretion of phenolsulphonphthalein, are necessary for a final conclusion. However, two facts are important in this discussion: (1) that when a mild degree of renal insufficiency develops after the administration of mercury it is of very short duration, and (2) that many patients with edema have tolerated large amounts of mercury, given at regular intervals, with subsequent satisfactory renal function.

Undoubtedly a shift in acid-base equilibrium toward the acid side occurred in all cases in which a sufficient dose of an acid-producing salt was given. Those salts which contain chloride produced it in greater degree and more rapidly than those which contain nitrate. Part of the diuretic effect of these salts is probably due to this change in the acid-base equilibrium, so that the presence of compensated, or even moderately uncompensated, acidosis is assumed to be a desirable action. Too marked acidosis may on the other hand, cause dangerous effects. When demonstrable renal insufficiency is present, administration of acid salts must be carried out cautiously. In many cases in which this treatment was given, the subsequent diuresis was very

beneficial. In other cases the development of more marked renal failure contraindicated their further use.

A large amount of both laboratory and clinical investigative work has been done on the relation of the concentration of plasma protein to the formation of edema. In this series of cases diuresis apparently occurred just as often in cases in which the value for plasma protein was low as in those in which the value was normal. As a matter of fact, our cases of lipoid nephrosis in which the value for plasma protein was lowest responded well to diuretics. In cases of lipoid nephrosis with very stubborn edema, Hartmann, Senn, Nelson and Perley²⁶ have injected solution of acacia intravenously, thus raising the osmotic pressure of the plasma, with some encouraging results. Diets⁸ high in protein given to increase the protein in the plasma, and secondarily to decrease the edema, have not been effective in our experience. A diet comparatively low in protein, in our study at least, did not prejudice the diuretic action of the drugs employed.

In any consideration of the action of these diuretic drugs, the general and renal effect must be considered. The acid chlorides alter the acid-base equilibrium and raise the level of plasma chlorides. Both factors aid diuresis.²⁷ In cases in which the value for plasma chloride is low, acid chlorides raise it to the effective diuretic level.²⁸ Nitrate apparently can cause a fall in the concentration of plasma chloride, which in turn is followed by a diminishing diuresis. This fact explains the beneficial substitution of chloride for nitrate. Too much chloride may give rise to renal insufficiency. Could this be caused by too great a shift in the pH of the renal cells, as suggested by Steglitz's²⁸ experiments? A balanced chloride action is thus desirable for developing its optimal general and renal diuretic effect. Blumgart, Gilligan, Levy and Brown²⁹ have shown that metaphyllin may be an ineffectual diuretic agent when the value for sodium in the plasma falls to a low concentration, even though the value for chloride be normal. When it was increased by the ingestion of a sodium salt, spontaneous polyuria occurred. They expressed the belief that an optimal concentration of sodium, in addition to that of chloride in the plasma, is important for diuresis and may in part be the reason for the production of diuresis by alkaline salts. Melville and Stehle,³⁰ in their experimental work with compounds of mercury, stressed their general action on tissue because there is a definite latent period before diuresis begins. Bieter's³¹ experiments on the action of mercury in plasma, and Engel's and Epstein's observations in the absorption of isotonic solution from the skin, also suggest a general effect on tissue. The experiments of Govaerts,³² and of Christian and Bartram,³³ on the other hand, emphasize the marked renal action in diuresis caused by compounds of mercury.

Recent advances in renal physiology suggest that different types of diuretics might have specific actions on

the glomerulus or tubule Schmitz³⁴ employing the creatinine clearance test, was able to show that merbaphen and ammophylline had quite different effects on the renal excretion of creatinine. Herrmann³⁵ obtained similar results. Because there is some question as to the exact significance of creatinine clearance by the kidney, we do not feel that the results of Schmitz and of Herrmann have yet established the facts that mercury exerts its diuretic action by diminishing reabsorption of water by the tubules, and that the effect of ammophylline depends on its increasing glomerular excretion. Experiments of Smith and his co-workers³⁶ with the renal excretion of certain sugars have suggested that these sugars pass through the glomerulus and are not reabsorbed by the tubules. It will be of interest to see how much new information these investigations can give in this subtle field of the renal action of diuretics.

Potassium salts have been known for many years to have a dehydrating effect on the animal organism. Wilks and Taylor³⁷ in 1863 administered potassium nitrate by mouth to a patient with nephritic edema, with success. The toxic effects of potassium salts, when administered by vein, deterred physicians for many years from using them in clinical medicine. Barker³⁸ has recently introduced the use of potassium chloride by mouth in cases of cardiac and renal edema. He has seen no toxic effects, and the diuretic effect, in some cases, has been very satisfactory. We have confirmed his results in a few cases. This action of potassium chloride suggested to us a trial of potassium nitrate in place of ammonium nitrate. The nitrate ion has definite diuretic properties, and potassium should have a greater dehydrating effect than the ammonium radical. We have used it in several cases of edema in the last few months and it has proved a valuable addition to the list of diuretic drugs. Further study as to its action on the blood and urine are now being carried out.

The ideal diuretic has yet to be discovered. In the last fifteen years, experimental work and clinical observation have added much to knowledge as to the action and therapeutic results of various types of diuretics. This should give much hope for their continued development in the future.

ABSTRACT OF DISCUSSION

DR M. HERBERT BARKER, Chicago. This therapeutic plan of diet and diuretic substances is effective in 75 per cent of the authors' cases. One must not be satisfied to treat the symptoms of edema. The edematous patient is always markedly wasted so that he must be built up generally and maintained. The plan given here lends itself well to the removal of fluid from the tissues and to the support and maintenance of the patient. One cannot emphasize the dietary care too much. The use of the specific diuretics requires consideration as to the type of patient. In my experience, patients of myocardial type tend to show a higher carbon dioxide combining power and indicate in the general check of acid base equilibrium that they are on the alkaline side. A diuretic plan composed of acidotic salts

and a diet with an acid ash has been extremely beneficial in my hands. The reverse, however, is true of the nephrotic group. They usually present high chlorides and relatively low carbon dioxide combining power and the acid-forming salts such as ammonium chloride and calcium chloride, frequently within a few days, while producing diuresis will carry them into a state of peculiar acidosis with depression and nitrogen retention. Ammonium nitrate, or even potassium chloride seems to be a much better salt in that particular case. I find that patients change very rapidly, depending on the plan in use, and that the plan that is effective one day may need definite changes within a few days. The optimum of hydration and dehydration is not easily measured, but in following the chlorides, the carbon dioxide and perhaps the serum proteins for concentration and dilution, one has a great adjunct in the care of these patients.

DR EDWARD J. STIEGLITZ, Chicago. Since Martin Fischer pointed it out, patients have been flooded with alkalis and sometimes their edema subsided and sometimes it got much worse. More recently, acid-forming salts ammonium chlorides and ammonium nitrate have been used with much better results. The fundamental reason probably lies in the tissues. But in part it may be in the kidney structure. It was demonstrated some years ago that when the urine is acid in reaction, the cells of the tubules are alkaline in reaction, and when the urine is made alkaline, the cells are acidified. The cells of the convoluted tubules in the loops of Henle have exactly the opposite reaction to the urine. Alkali therapy in a nephritic as well as in a normal individual tends to make the reaction of the cells opposite to their normal reaction, theoretically it is justifiable to assume that they are probably less efficient when their hydrogen ion concentration is not their normal one. On the other hand acidifying the urine more strongly with the addition of acid salts tends to alkalinize the reaction in the cells of the convoluted tubules in the loops of Henle, in other words to approach more the normal reaction. An effort has been directed toward the elimination of edema as water. Water is probably the least important part of the edema. Edema fluid is toxic; it contains a great deal of toxic material. The modern conception should consider edema as a protective mechanism to remove from the circulation toxic and noxious substances. If that is the case the prime consideration is not the removal of water alone but the removal of the toxic material that is responsible for the accumulation of water. During these diuretic periods as the edema subsides the patient, in the majority of instances, becomes much more intoxicated, much more sick than he was during the period of the accumulation. This does not mean that one should encourage edema nor try to treat it at all. That would be a very unjustified and dogmatic statement. It means that during the subsidence of the edema it is perhaps safer to cover the diuresis with an adequate water intake and perhaps let the patient lose 1 liter of his edema fluid daily plus 1 liter of fresh water so that the intoxication is not made too great.

DR NORMAN M. KEITH, Rochester, Minn. The problem of edema is very complicated. The fact that it is possible to rid the body of this abnormal fluid in a good percentage of cases of course does not mean that the patients are being cured of their primary disease. The point brought out by Dr Barker that the diet is important is especially to be stressed. We had a man with marked anasarca due to renal disease who was finally rid of his edema by different diuretics. At this time we found him in a condition much like a convalescent case of typhoid. The metabolism was low. He needed protein and when we gave it in large amounts he stored it for days and gradually came up to his original weight. The point brought up by Dr Steglitz is also fundamental because we have noted that when the amount of chloride administered is above a certain amount acidosis develops and with the acidosis the patient may have severe renal insufficiency. The chlorides must be above a certain level in the plasma for diuresis to be effective, but if it is too high it may affect the renal cells in some way that is not understood. Finally there is the question of renal insufficiency. Dr Steglitz brought up the point that some of these patients when they are dehydrated become toxic. We had a case of liver insufficiency with cirrhosis with very little jaundice and yet when this treatment was given the patient

developed a peculiar toxic mental state and the question at that time was whether the therapy had produced this condition or whether it was one of the incidents seen in that disease when left untreated. This patient recovered from the acute toxemia and later went through a similar course of diuretic treatment. During this period the accumulated fluid was passed and the patient is alive and well today. Two interesting facts brought out by this form of treatment are (1) the frequent development of a temporary acidosis and (2) temporary renal insufficiency. A very important practical question is to know how far to proceed with the treatment in each individual patient.

DIVIDED DOSES OF TYPHOID VACCINE IN THE FEVER THERAPY OF NEUROSYPHILIS

J. R. DRIVER, M.D.
AND
HENRY C. SHAW, M.D.
CLEVELAND

It is no longer necessary to defend the principle of fever therapy in the treatment of neurosyphilis, for Wagner-Jauregg's malaria treatment of dementia paralytica has had universal acceptance, and its value in other forms of resistant neurosyphilis has been firmly established. Soon after its introduction, however, it was recognized that inoculation with malaria was attended by certain dangers and limitations which precluded its general application for all cases. Generally speaking, only robust persons without serious physical sequelae should be inoculated. Also, it is found that approximately 10 per cent of the patients inoculated

labeled the trial of various foreign proteins in the fever treatment of neurosyphilis. Of these, typhoid vaccine has had by far the most extensive use. While it largely eliminates the objectionable features of malaria treatment and other disease-producing methods, the difficulty of producing high fever, comparable to those of malaria, consistently throughout a course of treatment, has been a serious drawback and has prevented a more general adoption of the method. In the past typhoid vaccine has been used largely for safety and convenience. Therapeutically, in the opinion of most investigators, it was inferior to malaria treatment.

The beneficial effects of fever therapy in neurosyphilis are roughly proportional to the height of the temperature obtained. Kirby³ thinks that temperatures above 105° F are necessary in order to obtain the maximum effect. Winslow, Miller and Noble⁴ believe that a high temperature, artificially produced, 104° F or higher, has a favorable influence on an established infection, while lower temperatures would seem to retard the formation of immune bodies. Thus, any procedure that would safely increase the fever-producing capacity of foreign proteins would probably also increase their therapeutic value. In order, throughout a course of treatment, to produce high temperatures by the intravenous injection of typhoid vaccine, it has been the usual custom to increase greatly the amount of each subsequent injection. Thus, doubling the previous dose is often resorted to, and amounts as high as from 2,000,000,000 to 4,000,000,000 organisms in a single injection have not uncommonly been reported. Even so, pyrexia comparable to that obtained by malaria has not been possible in all cases.

Chart 1.—Temperature reactions obtained in a patient treated by divided doses of typhoid vaccine given intravenously. The solid dots indicate the temperatures at the time each injection was made. Distinctly lower temperatures resulted from the first, second, third and fourth reactions.

have a partial or total immunity to malaria, making it necessary to adopt some other method of producing pyrexia. The difficulty of maintaining a suitable strain of tertian plasmodium, even in larger cities, is well recognized. For similar reasons, relapsing fever and sodoku have not fulfilled the requirements for a safe, efficient, easily available method of producing fever. Investigations, therefore, have continued in search of methods which would eliminate these objections.

The suggestion of Cowie and Calhoun,¹ of Barr, Du Bois and Cecil² and others, that the effect of malaria is due to the foreign protein nature of the paroxysm and not to a specific effect of the parasite itself, stimu-

In 1931, Nelson⁵ reported on "An Improved Method of Protein Fever Therapy in Neurosyphilis," using combined typhoid vaccine. The technic consisted in giving two daily intravenous injections of the vaccine in the following manner:

The first dose is given at any selected time and is of a size calculated to cause slight fever; the second is given during the height of the fever produced by the first—usually at the end of the second or third hour. The second dose seems to have the effect of "exploding" the charge supplied by the first and in this way relatively small doses are capable of producing fever apparently as high as desired—105°, 106°, 107° F.

Case records were submitted which clearly demonstrated the advantage of the double injection over the old single injection method.

Without knowledge of Nelson's report the following experience resulted in our investigation of the

divided dose technic of using typhoid vaccine in fever treatment

CASE 1 (chart 1)—E M a Negro, aged 31 had a meningo-vascular type of neurosyphilis, and on Nov 10, 1932, was inoculated with malaria. At the end of nine days no febrile reactions had occurred, and no malarial parasites were found on examination of blood smears. A dose of typhoid vaccine containing 25 000,000 organisms was given intravenously, followed by a rise in temperature to 100.8 F at the end of four hours. At six hours it had fallen to 99.5 F, at which time a second dose of 50,000,000 organisms was given. This produced an additional rise, with a fastigium of 106.5 F, three hours later. This unusual reaction was interpreted at the time as being a malarial paroxysm precipitated by the injection of the foreign protein. However, in the following three days no further rise in temperature took place, and examination of blood smears again failed to reveal any plasmodia. It was then decided to continue fever therapy by the use of typhoid vaccine, as had been our custom in the past in many similar instances of natural immunity to malaria. A dose of 50 000,000 organisms was given on November 22 with a peak temperature of 103.1 F. On the following day, a dose of 100 000 000 organisms resulted

It is advisable to avoid the use of antipyretics for relief of headache or other symptoms during the course of the treatment, as they may greatly diminish the fever reactions.

The first dose is given at any convenient time, preferably in the morning. Within from thirty minutes to two hours the patient usually experiences a chill lasting for a few minutes and followed by a rise in temperature. The second dose is then given after the rise is well established, i. e. 100 F or higher. The interval between doses should be not less than two hours. It is found that an interval of from three to six hours is equally satisfactory providing the temperature has not dropped to near normal by this time.

In many instances the fastigium lasts for only a few minutes so that unless the temperatures are taken frequently the peak cannot be recorded.

A course of treatment may consist of any number of reactions—as many as from ten to sixteen have been given. Subsequent courses may be given with equally satisfactory results after an interval of weeks or months.

It should be remembered that there is a great individualism in the tolerance of patients to the injection of foreign proteins, and although it is believed that this factor is less marked with

Chart 2—Temperature chart of a patient treated by divided and single doses of typhoid vaccine intravenously. In the seventh and tenth reactions no rise in temperature had occurred when the second doses were given. The results are similar to the second, third and eighth reactions in which single doses were used.

in a rise in temperature to 103.3 F. Two days later, November 25 a dose of 200 000,000 organisms produced a temperature of 103.1 F. At this point the possibility of the unusual initial reaction being due to the divided dose was suggested. Therefore on November 27, a dose of 200 000 000 organisms was given, causing an hour later a slight fever, the temperature being 99.1 F. Another dose of 200,000,000 organisms was then given resulting in a peak temperature of 105.4 F. On November 29, a dose of 400,000,000 organisms was injected. At the end of one and a quarter hours a temperature of 100 F had developed, and an additional dose of 400,000 000 organisms produced a rise in three hours to a peak of 105.4 F. Four additional reactions were given in a similar manner, resulting in temperatures of 105.8 F or higher.

This experience stimulated further study of the subject, and to date we have treated a total of twenty-one patients. Nineteen were suffering from various types of neurosyphilis, and two had resistant syphilis associated with interstitial keratitis and iritis.

TECHNIC

Fresh commercial typhoid vaccine is used containing 1 000 000 000 organisms per cubic centimeter. To 1 cc. of the vaccine 9 cc. of physiologic solution of sodium chloride is added. One cubic centimeter of this mixture contains 100 000 000 killed organisms. The diluted vaccine is kept in an icebox and can be used throughout the course of treatment. Injections are given preferably with a tuberculin syringe to ensure accurate dosage. If a fresh vaccine is used smaller doses are required. As a general rule treatment is given on alternate days although it can be given on successive days providing the temperature has returned to normal the reactions are well sustained and there are no other contraindications. Temperatures are taken rectally every half hour until the temperature has risen to 104 F and then every fifteen minutes until it falls to 104 F again. Thereafter the temperature is recorded hourly until normal.

the divided dose method of using the vaccine, yet careful attention and bedside study are perhaps required in greater measure than in most therapeutic procedures.

REPORT OF CASES

The following case histories illustrate some of the factors which contribute to the success or failure of the method.

CASE 2 (chart 2)—J T, a white man aged 38, suffering from a well developed case of dementia paralytica received the treatment outlined in table 1. In this case, temperatures from

TABLE 1—Treatment Employed in Case 2

	Date	Dose Millions	Interval Hours	Temperature F	Dose Millions	Highest Temperature F
1	2/8/33	10	1 1/2	100.8	10	101.4
2	2/10/33	2		Single dose		101.9
3	2/11/33	20		Single dose		101
4	2/14/33	20	1	100.2	20	104.4
5	2/15/33	20	1 1/2	100.3	20	104.7
6	2/16/33	100		Single dose		103.1
7	2/16/33	4	1	98.2	40	101.1
8	2/20/33	100		Single dose		102.9
9	2/21/33	12	2	100.0	12	101
10	2/21/33	2.0	1	98.4	2.0	101
11	2/21/33	2.0	1 1/2	100.6	2.0	101.4
12	2/25/33	2.0		100.4	2.0	101.1
13	2/27/33	2.0	4	100.5	2.0	101

104.4 to 106.9 F were obtained in all instances in which a rise in temperature had occurred before the second dose was given. When single doses were used the temperature was much lower. When fever had not been produced by the time the second dose was given the reactions were similar to those produced by single injections.

CASE 3 (chart 3)—F C a white woman aged 37 suffering from early dementia paralytica received the course of treatment outlined in table 2. In this case in each of the three reactions the sixth, eighth and ninth respectively three doses

were used In the sixth reaction the doses were spaced one-half hour apart, and there had been no production of fever when the third dose was given The highest temperature, 102.9 F, was, therefore, relatively low In the eighth and ninth reactions

TABLE 2—Treatment Employed in Case 3

Date	Dose Millions	Interval Hrs	Temperature F	Dose Millions	Interval Hrs	Temperature F	Dose Millions	Highest Temperature F
1 12/29/32	10	2	100.0	10				103.4
2 12/31/32	10	1	100.4	10				104.0
3 1/2/33	20	1	100.4	20				105.3
4 1/4/33	20	1	98.0	20				104.0
5 1/6/33	20	2½	101.1	20				105.8
6 1/8/33	25	½	98.6	25	½	98.6	25	102.9
7 1/10/33	35	2¼	101.7	35				105.3
8 1/12/33	35	1½	98.6	35	1	99.3	35	105.1
9 1/14/33	35	1	98.6	35	1½	101.3	35	104.9
10 1/15/33	35	2	100.0	35				105.1

it will be noted that there had been no fever when the second doses were given, while at the time the third doses were administered a rise in temperature had taken place the highest temperatures being 105.1 and 104.9 F, respectively A total dosage of 595,000,000 killed bacteria for the course of ten reactions is much lower than is generally used by the single injection method

CASE 4 (chart 4)—C W, a white woman suffering from tabes dorsalis with Charcot's joint of the right knee, was treated as outlined in table 3 In this patient fever was present before each second injection High temperatures comparable to those

Chart 3—Chart showing satisfactory temperature reactions obtained with divided small doses of typhoid vaccine The importance of a rise in temperature before second doses are given is illustrated in the fourth and sixth reactions

seen in malaria resulted from each reaction The highest temperature recorded occurred in the tenth reaction following an interval between doses of three hours A total dosage of only 350,000,000 organisms was used

TABLE 3—Treatment Employed in Case 4

Date	Dose Millions	Interval Hours	Temperature F	Dose Millions	Highest Temperature F
1 1/14/33	15	1¾	100.8	15	104.4

10 2/6/33	20	3	99.7	20	106.5

COMPARISON OF SINGLE AND DIVIDED DOSE METHODS

Single Injection Method—Using single injections of combined typhoid and paratyphoid vaccines MacKenzie⁶ treated thirty patients with dementia paralytica with the following results "Temperatures up to 107° F have been obtained, but a usual average is 103° F" Schlem,⁷ treating patients with dementia paralytica

6 MacKenzie J. M. Treatment of General Paralysis of Insane by Pyrotherapy. Brit. J. Ven. Dis. 5: 95-101 (April) 1929
7 Schlem G. W. U. S. Vet. Bur. Med. Bull. 6: 544-548 (July) 1930

stated that "The average maximum temperature obtained in all patients was 101.5° F" O'Leary⁸ found it necessary to give 350,000,000 organisms on several occasions to produce a temperature of more than 101 F Kemp and Stokes,⁹ in a series of thirty cases of neurosyphilis, found that with comparatively low dosage the average temperature was 103.67 F while with larger doses it was 104 F Kunde, Hall and Gerty,¹⁰ in cases of dementia paralytica, obtained temperatures varying from 102 to 104 F with an average of 103 F Robie¹¹ stated that he has never succeeded in getting a rise in temperature to over 104 F in the patients with dementia paralytica whom he has treated Goldsmith,¹² treating fifty-five patients with neurosyphilis, reported an average temperature of 103 F

Divided Dose Method—Nelson⁵ stated that by his double injection method "Fever apparently as high as desired—105, 106 or 107° F—may be produced by relatively small doses" Robinson and Johnson,¹³ using Nelson's method, obtained temperatures from 104 to 106 F Our experience corroborates that found by Nelson, and temperatures of 105 F or higher have been the rule when the technic has been carefully followed A rapidly developing immunity necessitating increasingly large subsequent doses is not so apparent in the divided dose technic, thus, smaller doses are required and often several satisfactory elevations of temperature

can be secured without any increase in the dosage (chart 4)

COMMENT

Various technics have been developed in an effort to determine the proper number of divided doses, the size of the dose best suited and the optimal time interval between injections

From these studies it is

believed that there is no particular advantage to be gained in giving more than two injections and that the amount of vaccine should be approximately the same for each dose Increase in dosage is entirely dependent on the character of the previous reaction

While it is entirely too soon to draw any final conclusions from the clinical results, yet the early improvement in our cases compares favorably with that seen following malaria treatment No serious untoward effects were observed in any case The reactions are tolerated unusually well without the marked prostration, anemia and loss of weight usually obtained with malaria treatment It is especially useful in instances in which malaria treatment is considered too dangerous or in which a natural or partial immunity to malaria exists It has the advantage of being always available and makes fever therapy possible for many patients to whom malaria therapy is not suitable

Definite myocardial disease, active tuberculosis and marked debility or cachexia are absolute contraindications to fever therapy

At present no one can offer a satisfactory explanation of the interesting phenomena produced by the divided dose technic of giving typhoid vaccine. Ecker²⁴ suggested that since the body has the property of promptly destroying or neutralizing some of the foreign protein after intravenous injection, this tendency may largely be satisfied by the first dose, permitting the second dose to cause an unusually intense reaction. Further studies along this line and on other phases of the subject in general have been planned.

SUMMARY

1 A series of nineteen patients with neurosyphilis and two with resistant syphilis associated with interstitial keratitis and iritis were treated with therapeutic fever, typhoid vaccine being administered intravenously, by the divided dose method, as described by Nelson

2 Providing an initial rise in temperature has resulted from the first dose, the second dose produces an additional elevation with a fastigium usually comparable to that resulting from a malarial paroxysm

3 The temperature of the patient should be taken before the second injection is made, and the vaccine should not be given unless a definite rise in temperature has occurred. The optimal interval between injections will vary between two and four hours.

4 The method is an excellent substitute for malaria treatment and brings satisfactory fever therapy within the reach of a still larger group of patients suffering from neuro-syphilis

5 Several courses of treatment can be given without the establishment of a permanent immunity, and chemotherapy can be combined with it if desired.

6 The higher temperatures made possible by this method clearly demonstrate the advantage to be gained over the older methods of producing fever by the injection of typhoid vaccine

ABSTRACT OF DISCUSSION

DR PAUL A. O'LEARY, Rochester, Minn. This report augments the reports that have been made on the value of nonspecific therapy other than malaria therapy in the treatment of syphilis and adds weight to the fact that the best therapeutic results occur in the group in which the higher temperatures are produced. In the series of cases I treated by typhoid vaccine and reported several years ago the incidence of serologic reversal was considerably less than following malaria therapy. At that time I had not used the split dosage method as originally described by Nelson. The debate is still going on as to the mechanism by which malaria therapy produces its therapeutic results. The proponents of the electrical temperature elevating contrivances lean to the fact that the heat per se is the factor while others believe the reticulo-endothelial system or the individual's defense mechanism produces the satisfactory results. At the present time the evidence inclines toward the concept that heat produced within or heat returned

within the body, produces the successful therapeutic results. Nonspecific therapy is of value in the treatment of syphilis other than neurosyphilis. The authors mentioned the use of the split dosage method in the treatment of interstitial keratitis and I likewise have found it of definite value in the treatment of keratitis in syphilitic children. The photophobia disappears within one half the time that it does when specific measures are used alone. In my experience the results in the treatment of latent and Wassermann fast syphilis have been less encouraging to date. The great value that has been derived from these studies on nonspecific therapy is the fact that in selected cases satisfactory serologic and clinical results may be obtained when the arsphenamines, bismuth compounds and preparations of mercury have failed. Frequently the concurrent use of specific and nonspecific therapy augments, hastens and intensifies the results usually obtained by one or the other method when used alone.

DR M O NELSON, Tulsa, Okla. I am glad that some one else has tried this method, because my efforts to interest others in it have been rather unsuccessful. In fact, it was only with the persistent encouragement of Dr Stokes that its development was carried to something like completion of technical detail, in spite of meager opportunity. The authors speak of "divided doses", the term "double" or "coupled" doses seems a trifle more accurate. Certainly the effect produced is not merely a cumulative one. The two doses are timed and have a complementary and differing action, like the combination

Chart 4.—Temperature reactions obtained in a patient given divided small doses of typhoid vaccine. Fever comparable to malaria resulted. A definite rise in temperature occurred before each second injection was made. Several satisfactory reactions were secured without the necessity of increasing the dosage.

of powder and a lighted match. The authors say that the second dose will not raise the temperature if the first dose has not caused fever. My own experience has been that it is the timing that is important, for I have often seen very high temperatures following the second dose, even when the first dose had not caused any elevation of temperature at all. A little experience with the method may be necessary to secure maximum effectiveness and it is important to follow technical details strictly. A partial list of these details appeared in the May, 1933 issue of the *Southern Medical Journal*. From the excellent results obtained I am convinced that this method of treatment is at least as effective as malaria and in one case it accomplished what malaria had failed to do. While in some of the larger institutions malaria treatment may be found more convenient, the ready availability of the double injection method makes it seem likely that it could be made to replace malaria almost entirely in general use. It has the advantage of being applicable early in the course of resistant syphilis before serious organic damage has occurred and at the very time when such a method is capable of doing the most good.

DR. LOUIS A. BRUNTING, Rochester, Minn. It is generally conceded that the old technique of the use of typhoid vaccine by single injection even in enormous dosage produces reactions that are decidedly inferior to those of malaria. Following the original report by Nelson, I have used typhoid vaccine in broken doses as he specifies especially in those patients who are resistant to inoculation by malaria or in whom the course is interrupted spontaneously after a few fever bouts as is so often the case in the southern European patient. The method has the advantage over malaria as with radiotherapy or superdilatation that the individual paroxysms can be regulated and modified as to time and to severity according to the condition of the patient. A certain amount of experience and control is

essential in the selection of proper cases and in the grading of dosage to provoke optimal reactions. Fevers of from 105 to 106 F are not uncommon, and on one occasion a rise to 108 F followed the administration of a double dose of 150 million organisms three hours apart. As a rule the febrile reactions by this method are more abrupt than with malaria but are of shorter duration, which can be demonstrated by using an electrical recording potentiometer with the rectal electrode in place for the duration of the paroxysm. There is a surprising individual variation among patients under fever therapy. As a rule it is well to avoid this method of therapy in those who present much involvement of the lower cord such as tabes with cord bladder or progressive ataxia, or those with acute syphilitic myelitis. Not infrequently such symptoms are aggravated by vigorous fever treatment. During the course of treatment, one of the most important laboratory aids in the recognition of toxemia is the level of the blood urea. Patients under malaria treatment sometimes show an alarming increase in the blood urea after four or five paroxysms, and in these the course is often stopped short of the desired number of fevers. It has been my experience recently that such a rise in the urea has been most marked when the loss of fluid by perspiration was greatest and especially in the summer months. I assumed that the elevation was merely a relative increase, due to concentration, and on this assumption proceeded to force fluids by mouth and by vein when necessary, to a total of 4 to 5 liters daily. The results have been quite satisfactory. In most instances the urea is reduced to its normal level, symptoms of dehydration disappear, and it is rarely necessary to stop treatment on this account short of the desired number of paroxysms.

DR J. R. DRIVER, Cleveland. It is important to emphasize that the split dose technic of using typhoid vaccine in fever therapy may present some danger if at the time the second dose is given, an unusually high temperature has resulted from the first injection. This can be illustrated by an example that came to my attention a few days ago. A patient suffering from chronic arthritis was given an initial dose of 25 million which at the end of two hours had produced a temperature of 103.5 F. This high fever was accompanied by convulsions and unconsciousness lasting for four hours. Following the use of carbon dioxide inhalations, injections of epinephrine, soluble barbitol and chloral hydrate cold packs and a saline infusion the temperature returned slowly to normal in ten hours. On the following day the patient felt perfectly well and his joint symptoms had disappeared. On the day this patient was treated the temperature of the room was approximately 95 F and unusually humid. The symptoms were those usually seen in a heat stroke. While it is entirely possible that this patient was extremely sensitive to intravenous protein, it may be that the second injection precipitated a heat stroke as a result of the unusually hot day. As a general principle, in using this therapy, the second injection should not be given if a temperature of 103 F or over resulted from the first dose.

Technic in Palpation.—The sensitiveness of hands and finger tips must be almost as variable as their character and shape. I believe we chiefly fail in palpation through lack of the art of "fine adjustment," to borrow a term from the microscope. It is scarcely ever necessary or useful to examine forcibly or roughly. Gross abnormalities we are only likely to miss if we are hasty or careless. But again it is the slighter abnormalities that are most valuable to us and our patients and these are only to be detected by the cultivation of a technic which is at once gentle and searching. The texture and qualities of the skin and the hair, whether we are looking for myxedema or testing the lost luster in the locks of an ailing child, are assayed by the fingers as well as the eyes. The slight edema of the skin over an empyema or other deep supuration is more worthy of discovery than the deep and obvious pitting of hydremic nephritis and only the trained and expectant thumb and forefinger can do it. The tiny anal fissure so often the cause of misleading and widely distributed pain and quite commonly missed can be appreciated as well by the forefinger as by the speculum, the feel of the lesion reminds one of the roughness of the button hole in the lapel of one's coat.—Ryle, J. A. *The Training and Use of the Senses in Clinical Work*, *Guy's Hosp Gaz* 47:421 (Oct. 28) 1933.

GESTATIONAL POLYNEURITIS

E. D. PLASS, M.D.

IOWA CITY

AND

W. F. MENGERT, M.D.

PHILADELPHIA

There have recently appeared several reports on gestational polyneuritis (neuronitis), emphasizing the clinical and pathologic aspects of this little known disease (Berkwitz and Lufkin,¹ Wilson and Garvey, McGoogan,² Hoffman³ and Strauss and McDonald⁴). Having seen twelve certain or probable cases within the past seven years, we are persuaded that the condition is not so rare as is generally thought and that a wider knowledge of the essential clinical picture will increase the frequency with which the diagnosis is made and will proportionately diminish the number of patients reported as succumbing to "late toxic vomiting of pregnancy." It is our purpose to discuss particularly the clinical observations in the light of the recorded cases and of our own experience.

ETIOLOGY

It has been commonly assumed that the disturbance is the direct result of the action of a toxin which is elaborated by the product of conception and which has an especial affinity for certain parts of the nervous system. No evidence is available to support this hypothesis, which, moreover, is rendered improbable by the fact that termination of the pregnancy frequently fails to arrest the progress of the disease. More recently, Berkwitz and Lufkin,¹ McGoogan,² Hoffman³ and Strauss and McDonald⁴ have called attention to the similarity of the nervous manifestations to those of beriberi and pellagra and have suggested that a deficiency of vitamin B (complex) may be responsible. The evidence supporting this position is not completely convincing, but the suggestion warrants serious consideration, since it offers a method of prophylactic and curative treatment not otherwise available.

PATHOLOGY

Visceral lesions are usually confined to mild degenerative changes in the various organs—kidney, heart, liver, suprarenals and the like. Grossly, the brain, spinal cord and peripheral nerves usually appear normal, although petechial hemorrhages may be detected, especially in the cerebrum and the meninges. Microscopically, the peripheral nerves show degenerative changes, while in the spinal cord, particularly in the anterior horn cells, there may be swelling of the cells with loss of the Nissl substance and occasionally a definite necrosis. Cerebral lesions are usually limited to petechiae. The involved muscles show marked degenerative changes.

From the Department of Obstetrics and Gynecology, State University of Iowa College of Medicine.

Read before the Section on Obstetrics, Gynecology and Abdominal Surgery at the Eighty-Fourth Annual Session of the American Medical Association, Milwaukee, June 15, 1933.

⁵ Strauss M. B. and McDonald W. J. Polyneuritis of Pregnancy, a Dietary Deficiency Disorder. *J. A. M. A.* 100:1320-1323 (April 29) 1933.

INCIDENCE

No estimate of the frequency of polyneuritis can be offered, although it is undoubtedly less rare than is commonly thought. Many cases of so-called late toxic vomiting of pregnancy should be placed in this category, as can be demonstrated by a careful survey of the reports in the literature. In other instances there may be a suspicion of "hysteria" because of the character of the subjective complaints and the almost complete absence of evidence of visceral disease. In any doubtful case, careful neurologic examination is demanded, since it is only in this way that polyneuritis can be diagnosed.

OCCURRENCE

The disease occurs more commonly in those pregnant for the first or second time, although women with a greater number of previous gestations are not exempt. There is no age relationship, the majority of cases occur between the ages of 20 and 35 years, when child-bearing is more common. Patients who have previously exhibited evidences of mental instability may be more susceptible.

ONSET

Gestational polyneuritis, of the type under consideration, almost invariably develops late in the course of, or following, an attack of hyperemesis gravidarum, making its appearance from twelve to twenty weeks after conception. It differs in this respect from those forms of isolated nerve involvement which may develop at any time during pregnancy or after delivery, without relation to nausea and vomiting.

SIGNS AND SYMPTOMS

There is a tendency to regard the early evidences of the neuritis merely as recurrences of a neurosis, since in many instances the patients who develop the condition have suffered earlier in their pregnancies from hyperemesis gravidarum, which has responded to simple treatment and which has therefore been viewed as "neurotic" in character. This is particularly true of the subjective complaints, such as the generalized weakness, the hyperesthesia and the tachycardia, which are so frequent in functional nervous disorders.

Chief Symptoms and Signs on Which the Diagnosis Depends—General weakness usually first appears in the lower extremities and may be limited to them. Ordinarily, the extensor muscles are more involved than the flexors, although the distribution is not uniform. The ankles and wrists may be less affected than the knees and elbows, or the paralysis may be more clearly of the ascending type. With the increasing weakness there is evident atrophy of the muscles which become soft and flabby.

Hyperesthesia in the affected parts is extremely variable. Occasionally the skin is hypersensitive but more commonly increased tenderness is elicited only by pressure deep into the muscles or over the nerve trunks. Placing the nerves on tension as by forcible flexion at the ankles or raising the straight leg on the abdomen, produces exquisite pain.

Tachycardia is almost uniformly present and may be among the earliest changes to attract attention. The cardiac rate is not altered by physiologic doses of atropine, a fact that suggests actual involvement of the vagus. Electrocardiograms give no evidence of abnormal cardiac action other than the increased heart rate.

Absence of the tendon reflexes in the affected extremities points to involvement of the lower neurons. As a rule, the knee jerks and achilles reflexes are lost first while the biceps and triceps jerks may be merely weakened or may disappear relatively late in the disease. Plantar stimulation and tibial pressure may evoke no response or one that cannot be easily interpreted.

Korsakoff's psychosis, with loss of recent memory, disorientation as to time and place and a tendency toward confabulation denotes cerebral involvement. It may appear late and, in mild cases, may disappear within a week or two. On the other hand, it usually persists for some months and may be permanent, particularly as regards the loss of recent memory.

Less Characteristic and More Variable Conditions—Ocular nystagmus, lateral and vertical, ocular squint more commonly divergent, and diplopia may result from involvement of the oculomotor muscles.

Optic neuritis may be indicated by indistinct, raised disk margins and slightly enlarged veins and may result in dimness of vision. On the other hand, ophthalmoscopic examinations may be negative and yet the dimness of vision may be attributable to an optic neuritis. Retinal hemorrhages of the "flame" variety have been rather commonly reported.

Exophthalmos has been recorded but is rare.

Central deafness is occasionally evident. There is good evidence that the actual auditory apparatus is adequate as shown by the prompt turning of the head in the direction of an unusual sound, but that the receptivity of the cerebrum is disturbed, so that response to questions is greatly delayed. In other instances there is evidence of nerve deafness, pointing to involvement of the auditory nerve. Auditory hallucinations have also been observed.

Delirium or drowsiness may develop in association with the psychosis, or quite independent of the mental alterations characteristic of the Korsakoff syndrome.

Choreiform movements of the head and face have been observed but are uncommon.

Dysphagia may result from paralysis of the muscles of deglutition, dysphonia, from involvement of the laryngeal and pharyngeal apparatus, while dyspnea may be due to paralysis of the diaphragm or the intercostals.

Pain in the involved extremities, independent of motion or pressure is rarely prominent but may occasionally demand attention.

Loss of positional sense is usually present as a manifestation of the ataxia of the extremities.

Involuntary urination and defecation have been noted rather frequently but appear more commonly late in the disease. In other instances there may be difficulty in urinating and catheterization may be necessary.

Jaundice has been described but is not common. Even in the patients who become icteric there is usually no marked necrosis of the hepatic cells.

Numbness is occasionally a prominent symptom even when there are no other evidences of sensory disturbance.

Paralysis of the diaphragm may be present as suggested by a costal type of respiration with the abdomen sinking with each inspiration or as shown by fluoroscopic examination. There may be an associated partial atelectasis of the lungs.

Laboratory Examinations—These do not generally give useful information although variations from normal may be noted at times. The urine is usually

normal but may show albumin and casts, especially when dehydration is pronounced. The blood commonly shows a moderate hypochromic anemia and occasionally a slight leukocytosis. Blood chemical studies ordinarily reveal no alteration from normal, but in rare instances there may be evidence of a moderate nitrogen retention. The carbon dioxide combining power is normal or slightly increased, and the hydrogen ion concentration tends to approach the upper limit of normal. The spinal fluid is under normal tension and shows no abnormal elements. There may be absence of free hydrochloric acid in the gastric contents. The blood and spinal fluid Wassermann reactions are commonly negative. Temperature elevations are uncommon except in the presence of an intercurrent infection or as a terminal event. Blood pressure readings are usually normal.

PROGNOSIS

In the forty-eight cases gathered from the literature by Berkwitz and Lufkin there were nine deaths—a mortality of 18 per cent. However, in the recent reports from this country the death rate was much greater, possibly because the condition was recognized more definitely in patients who succumbed early.

Percentage of Fatal Cases in Recent Literature

Author	Number of Cases	Deaths	Per Cent Fatal
Berkwitz and Lufkin ¹	4	9	75
Strauss and McDonald ²	3	0	0
McGoogan ³	5	4	80
Hoffman ⁴	1	1	100
Wilson and Garvey ⁵	2	3	100
Plass and Mengert	12	8	67
Total	28	19	68

When recovery does occur, it is usually slow but reasonably complete. Occasionally, however, the nerve changes are too extensive and the patient never regains the use of the involved extremities. In the four patients whom we have seen survive, a marked and rapid increase in weight was a prominent part of the convalescence. Patients who survive more than two weeks after the diagnosis can be made on physical examination have a relatively good chance of complete recovery. In fulminating cases, death may ensue within three or four days of the first symptom. Death is occasionally due to intercurrent disease but usually occurs because of complete paralysis of respiration or of swallowing.

TREATMENT

On the basis of the hypothesis that the disease results from a deficiency of vitamin B, intelligent prophylaxis would demand attention to securing an adequate consumption of this accessory food factor during and after hyperemesis gravidarum. With the recent tendency to force a high carbohydrate diet on patients with vomiting of pregnancy, there would seem to be an increased risk of producing vitamin deficiencies unless special care is paid to the inclusion of foods rich in these factors.

Curative treatment is generally ineffective unless one is impressed by the results of vitamin B feedings in the three patients of Strauss and McDonald. It would appear that their cases were mild in character, but the record of 100 per cent recoveries is impressive.

Emptying the uterus, as soon as a definite diagnosis is made, has not been so effective as to make it the

treatment of choice, although the association of the condition with pregnancy in an apparent cause-and-effect relationship presents a strong argument for therapeutic abortion. The fact that, in certain instances, the disease appears or becomes aggravated after the uterus has been emptied, or after the fetus has died, speaks against a toxic etiology and against too great reliance on termination of pregnancy as a therapeutic aid.

The possibility that the disease may appear in an aggravated form in a subsequent pregnancy constitutes sufficient reason for recommending contraception or sterilization for those patients who may recover.

The diet should be nutritious as well as vitamin containing. A plentiful intake of fluids should be assured, by mouth if vomiting is not frequent but by other routes if oral feedings are not well tolerated. Dehydration may be present and must be combated.

Heat and salicylates are most useful for the control of pain. The infra-red lamp, the heat cradle and the electric pad are helpful. Opiates should be used cautiously because of the chronic nature of the disorder.

Massage and electrotherapy are valuable adjuncts to the later treatment when reestablishment of function is particularly sought.

Orthopedic appliances are useful to combat the tendency of the involved extremities to develop contractures.

SUMMARY

Gestational polyneuritis commonly follows or develops concurrently with hyperemesis gravidarum. There is a tendency to explain the symptoms on the basis of hysteria unless a neurologic examination is made, since there are usually no evidences of visceral disease. The cardinal observations include (1) general weakness more marked in the legs and in the extensor muscles, (2) sensory disturbances, (3) tachycardia, for which no organic explanation can be elicited, (4) marked diminution or absence of the various tendon reflexes, and (5) a psychosis of the Korsakoff type.

The etiology is unknown, but the disease is variously explained as due to (1) a toxin developed by the conceptus or (2) a deficiency in vitamin B intake.

Pathologic changes in the viscera are scarcely significant, but degenerative changes in the peripheral nerves and spinal cord and petechial hemorrhages in the cerebrum offer an explanation for the neurologic manifestations.

The prognosis is poor. If the patient survives the first two weeks, slow recovery usually ensues, but it may never be complete.

Treatment is empirical and none too successful. Prophylaxis on the basis of high vitamin feeding offers the best hope for improving treatment. Therapeutic abortion is well advised but the results are frequently disappointing.

ABSTRACT OF DISCUSSION

DR. RALPH H. LUKART, Omaha. Cowgill of Yale demonstrated the lack of foundation for the hypothesis that polyneuritis is caused by a toxin. He has shown that, if the disturbance is not too advanced, relief can be procured by stabilizing the vitamin balance, particularly the vitamin B complex. This includes the antineuritic part of this vitamin, which formerly was called vitamin G. A patient with severe vomiting in pregnancy developed symptoms almost identical to beriberi, Korsakoff's syndrome and pellagra. Forced feeding of the vitamin B complex was instituted, and because of the results the case was reported at the obstetric meeting at Memphis last

October The paper by Straus and McDonald, referred to by the authors, emphasized the important fact that there is a decrease and often a lack of free hydrochloric acid in the gastric juice of pregnant women. In all these conditions there is a history of vomiting, diarrhea, loss of appetite, emaciation or some hepatic disturbance. It is well known that avitaminosis causes a loss of appetite which in turn prevents ingestion of vitamins, thus establishing a vicious circle. In these various disturbances evidenced by polyneuritis the etiology simmers itself down to a failure on the part of the individual to digest, assimilate or metabolize the needed vitamins to maintain a proper vitamin balance.

DR J H SURE, Milwaukee I want to call attention to a condition not quite so severe as polyneuritis, a form of toxemia that occurs in the latter months of pregnancy and is associated with pain and tingling in the extremities, which will not allow the patient to sleep. In former years it was my practice to use salicylates and barbiturates and even narcotics, but with no relief. Now, however, I have learned that these symptoms are caused by calcium deficiencies. It required at least 120 to 150 grams of calcium lactate daily to get relief from pain, and whenever the dose was cut down the pain recurred.

DR RAE T LAVAKE, Minneapolis I should like to ask the authors whether they have arrived at any definite conclusions as to how long one can subject these patients to non-operative treatment of any type and feel that they are safe. Four such cases have come under my observation and in each instance, from an examination of their charts, I would have terminated the pregnancy from indications of pulse and mental condition weeks before the neuritis developed. Gestational polyneuritis, to my mind, represents one of the possible terminal stages of early toxemia of pregnancy. If pregnancy is not terminated early, I feel that 60 per cent is possibly a low mortality rate.

DR F H FALLS, Chicago During the five years that I was at the University of Iowa I saw more of these cases than I have seen before or since. I also noted the rapidity in pulse and the similarity between the symptoms these patients manifest and those of a thyrotoxicosis. Since coming back to Chicago I have been interested in the question of hyperemesis gravidarum and thyrotoxicosis and have taken a large number of basal rates in patients suffering from hyperemesis gravidarum. The basal rate is nearly always high, not plus 10 or plus 20 but as high as plus 60 or 70, in two cases it was 111 and 109. A large percentage of them will recover from hyperemesis gravidarum, and the polyneuritis will improve if they are given compound solution of iodine. There is no question that a woman with hyperemesis gravidarum is suffering from an avitaminosis, but there are other things besides, and the polyneuritis may well be a combination of the toxemia with the thyrotoxicosis superimposed on an avitaminosis. I agree with Dr LaVake in that when I see severe or even beginning evidence of polyneuritis and a rising pulse up to 120 I consider seriously the emptying of the uterus. On the other hand I never have emptied the uterus unless I have proved to my own satisfaction that I cannot control conditions by the use of thirty drops of compound solution of iodine a day. With this treatment I have been able to carry along practically all patients without emptying the uterus except in those entering the clinic in a dying condition.

DR F J SCHATZ, St Cloud, Minn I wish to report a case that I saw in 1923 in a secundipara aged 28 in order to bring out a point not mentioned by Drs Plass and Mengert. The first pregnancy was normal. In her second pregnancy, at six months she developed weakness of the lower extremities, severe pain and gradual paralysis. There were no complications above the waistline. She went on to full term and delivered normally. A subsequent pregnancy two years later was normal with an easy delivery. She is still alive in good health but with complete paralysis of the lower extremities.

DR L D PLESS, Iowa City I am grateful to Dr Lunkart for having emphasized the possibility of polyneuritis being an avitaminosis. Dr Sure intimated that the pain in polyneuritis could be controlled by calcium therapy. My experience in one case would indicate that calcium is not so effective as in other neuritic pains in the extremities. I am not sure when the

pregnancy should be ended. Most of my patients have come after mental symptoms were well developed, actually being admitted because of a psychosis. Certainly at that stage of the disease, emptying of the uterus is not an effective therapeutic procedure. In one case the uterus was emptied within a week after the tachycardia had appeared and the therapeutic abortion apparently had a good effect, in other cases it has not been so effective. There is such wide variation in the time of appearance of mental disturbances that the development of a psychosis is not an adequate indication for abortion. In the case presented, mental symptoms were first noted three weeks after the uterus was emptied. I would emphasize again that prophylaxis is infinitely better than the cure, and, on the avitaminosis hypothesis, it should be possible to provide protection by adequate vitamin feeding during and after the hyperemesis. In answer to Dr Falls, I may say that in one or two cases the basal metabolic rates were not excessively high, no higher than one would expect in a normal pregnancy. I am glad that Dr Schatz brought out the possibility that the paralysis may be permanent. I would also emphasize that some of the mental symptoms may be permanent. I have had one patient under observation for about eighteen months who still has loss of recent memory. She can recall distant events perfectly well but cannot remember what happened yesterday or last week. The possible permanence of some of the nervous manifestations must be kept in mind in any case of gestational polyneuritis.

THE BLADDER POST PARTUM

LAWRENCE M RANDALL, MD

AND

STEPHEN E MURRAY, MD

Fellow in Obstetrics and Gynecology the Mayo Foundation
ROCHESTER, MINN

For several years, we have followed a definite routine when caring for the urinary bladder post partum. This paper is concerned with an outline of this care, and a review of obstetric conditions that may influence the behavior of the bladder during the puerperium.

Our care of the urinary bladder post partum is based on the principles that overdistention of the bladder, and the presence of residual urine, favor infection of the urinary tract. We recognize a small group of women who are unable to void spontaneously post partum, apparently from no demonstrable cause. Nervous inhibition, posture and decreased intra-abdominal pressure may explain this. In caring for these patients, as well as all others, an attempt is made to cause spontaneous urination by such means as warm external "pitcher douches." However these are not persisted in to the point of exhausting the patient. We believe that too great value may be placed on spontaneous urination during the puerperium through fear that catheterization will cause infection of the urinary tract. It has been shown by Cabot¹ that infection rarely, if ever, is caused by aseptic drainage by catheter in itself but that previous overdistention and the persistent presence of residual urine are etiologic factors. The observations of Mengert and Lee² and others have demonstrated the presence of dilated, atonic ureters during pregnancy. This condition persists for a time post partum and would seem to make desirable avoidance of distention and residual urine.

In our experience it has been necessary to drain by catheter, the bladders of approximately 15 per cent of

puerperal women. Our patients are usually catheterized on the delivery table and so return to their rooms with the bladder empty. The average parturient woman is not dehydrated, but she is encouraged to take fluids as soon as any nausea that may have been incident to the anesthesia has disappeared. The majority of puerperal women have normal renal function, hence the secretion of urine should not be materially altered.

It would seem, therefore, that the decision whether the catheter is to be used should depend on the inability of the patient to void in the presence of a desire to do so or on evidence of a full bladder being gained by abdominal palpation. Not infrequently evidence of a full bladder will be elicited without the woman being conscious of a desire to void. However, if the patient does not void within eight to twelve hours post partum the catheter is used as a rule. Subsequently she is given an opportunity to void spontaneously, but if she is unable to do so the catheter is inserted at intervals of eight hours. Following the first spontaneous urination she is again catheterized to learn if any residual urine is present. The average patient with retention is able to empty the bladder completely and spontaneously by the third day post partum.

Those patients who begin to void spontaneously, but frequently and in small amount, are catheterized after one of their voidings, and not infrequently residual urine is found. These women are then catheterized after each urination until the quantity of residual urine is less than 50 cc. A few cubic centimeters of solution of silver nitrate, 1 per cent, is instilled through the catheter after each drainage for the antiseptic and stimulatory effect.

The regimen outlined in the preceding paragraphs has been in force for eight years, with no untoward results.

Nine hundred and eighty-four patients were studied post partum to determine, if possible, the cause of retention of urine in the puerperium. The selection was made solely on the basis of ability or inability of the patient to empty the bladder spontaneously. Patients who were able to void spontaneously numbered 776, those who had retention necessitating catheterization numbered 208. Of the patients who could urinate spontaneously, 63 per cent were multiparas and 37 per cent primiparas, of those who were catheterized 26 per cent were multiparas and 74 per cent primiparas.

The pelvic measurements were recorded to determine the incidence of deviation from normal in the two groups. Of the 776 women who were able to void spontaneously post partum, 90.52 per cent had normal measurements. The remaining 9.48 per cent had pelvic contraction, classified as follows: unspecified contraction, 1.1 per cent, flat pelvis, 1.0 per cent, generally contracted pelvis, 2.5 per cent, funnel pelvis 0.28 per cent and contraction of the pelvic outlet, 4.6 per cent. Of the 208 women who had retention of urine post partum, 79.49 per cent had normal pelvic measurements. The remaining 21.51 per cent had pelvic contraction classified as follows: unspecified contraction 3 per cent, flat pelvis, 2.7 per cent, generally contracted pelvis 1.2 per cent, funnel pelvis 0.61 per cent and contraction of the outlet, 1.4 per cent. There is no significant difference in the proportion of the various pelvic abnormalities except in contraction of the outlet. This condition is naturally associated with a considerable proportion of cases in which there is trauma to the soft tissues of the perineum and in which episiotomy and low forceps deliveries are necessary.

The frequency of certain factors that might be associated with increased trauma to the maternal soft tissues was studied. The 776 cases in which urination was spontaneous post partum were studied first. In forty cases (5.2 per cent) manual rotation from the occipitoposterior position to the occipito-anterior position was carried out, in seven cases (0.9 per cent) the same change in position was effected by means of forceps. There were seventy-one cases (9.2 per cent) in which the occiput rotated spontaneously from posterior to anterior. In ten cases (1.3 per cent) the cervix was dilated manually, and in four cases (0.5 per cent) the cervix was incised because it failed to dilate. Sixty patients (7.7 per cent) had dry labors. Episiotomy was performed in 326 cases (42 per cent). Next, the 208 cases in which catheterization was necessary were studied. In seventeen cases (8.1 per cent) manual rotation from the occipitoposterior to the occipito-anterior position was effected. There were four cases (1.9 per cent) in which the same change in position was brought

The percentage of patients who are unable to empty the bladder spontaneously increases progressively with the length of labor.

about by means of forceps, and eleven cases (5.2 per cent) in which it took place spontaneously. Manual dilatation was performed in six cases (2.9 per cent) and incision of the cervix in two cases (0.96 per cent). Dry labor occurred in nineteen cases (9.1 per cent). Episiotomy, with repair, was performed in 150 cases (75 per cent).

It would seem that occipitoposterior presentation, whether rotation is spontaneous or whether manipulation is necessary to correct it, has little to do with subsequent retention of urine except as it affects the length of labor. Likewise, conditions that may be associated with increased trauma to the cervix, such as manual dilation of the cervix, Dührssen's incision of the cervix, and loss of the bag of waters before dilatation begins, seem to have no bearing on the subsequent ability of the patient to void. Trauma of the pelvic floor and vulva, associated with episiotomy, apparently increases the chances of retention of urine post partum.

The numbers of various operative deliveries through the vagina were as follows. Among the cases in which urination was spontaneous low forceps was used in 144 cases (19 per cent), midforceps in thirty-one cases

(4 per cent), and high forceps in two cases (0.25 per cent), in four cases (0.5 per cent) the after-coming head required operative delivery, and version and extraction were performed also in four cases (0.5 per cent). The total incidence of operative delivery was 24 per cent. Among the cases in which catheterization was necessary, low forceps was employed in seventy-seven cases (37 per cent), midforceps in eighteen cases (8.6 per cent), and high forceps in one case (0.48 per cent). There were fourteen cases (6.7 per cent) in which it was necessary to use forceps on the after-coming head, and two cases (0.96 per cent) in which version and extraction were performed. The total incidence of operative delivery was 53.74 per cent. Of the patients who required catheterization, 74 per cent were primiparas, hence the higher incidence of operative delivery. Naturally, among primiparas who underwent operative delivery, the labors were longer and the proportion of cases in which episiotomy was performed was high (92 per cent). The factors of fatigue and of reaction to analgesia and anesthesia perhaps played a part in urinary retention in this group of cases.

Position and presentation of the infant were virtually of the same distribution in the two groups, except that among the cases in which urination was spontaneous the incidence of breech presentation was 2.2 per cent and among the cases in which catheterization was necessary, 8.1 per cent. It may be that the more rapid passage of the after-coming head through the birth canal is a factor in causing retention, but the incidence of episiotomy in breech deliveries is high and this factor may be the more prominent contributory cause.

Labor had been induced for various reasons in 30 per cent of the cases in which catheterization was necessary and in 19 per cent of the cases in which urination was spontaneous. The methods of induction of labor bore no relation to the subsequent behavior of the bladder.

SUMMARY AND CONCLUSIONS

The percentage of patients who cannot urinate spontaneously increases as the length of labor increases. This suggests that fatigue is a factor. In addition those patients who go through prolonged labor, as a rule have had more analgesia during labor and more anesthesia during delivery than those whose labor is of shorter duration. These factors may affect the ability to void.

As compared with the patients who could urinate spontaneously post partum the incidence of pelvic contraction was found to be twice as great among patients with retention post partum. Contraction of the pelvic outlet was the most common form of pelvic contraction. Naturally the percentage of episiotomy and forceps delivery was high in this group of cases.

Factors thought to be associated with increased trauma to the vaginal wall and cervix such as spontaneous rotation in cases of occipitoposterior position, operative correction of errors of rotation, manual dilatation of the cervix, incision of the cervix, and premature rupture of the bag of waters did not materially influence the frequency of retention of urine. Injury to the bladder or ureters did not occur in any case.

Operative delivery through the vagina had been performed in 53 per cent of the cases in which catheterization was necessary and in 25 per cent of the cases in which voiding was spontaneous. Of the women who underwent operative vaginal delivery 76 per cent were primiparas. 70 per cent of the operations were deliveries by low forceps.

Episiotomy with repair had been performed in 72 per cent of the cases in which catheterization was necessary and in 42 per cent of the cases in which voiding was spontaneous. Ninety-two per cent of the primiparas and 76 per cent of the multiparas who underwent operative delivery also had episiotomy. Eighty-four per cent of the operations were accompanied by episiotomy.

It would appear, therefore, that primiparity associated with episiotomy and repair is most frequently followed by urinary retention. Prolonged labor, delivery by forceps and contraction of the pelvic outlet exist as contributory causes. While this regimen of care of the bladder post partum has been carried out 3,500 women have been confined with no untoward effect on the urinary tract. We believe, therefore, that avoidance of overdistention and residual urine must in part account for the freedom from infection of the urinary tract among patients who are catheterized post partum. Further, it would seem that the act of catheterization properly performed, before overdistention occurs and residual urine appears, is a safe procedure.

DILATATION OF THE KIDNEY PELVIS AND URETER DURING PREGNANCY AND THE PUERPERIUM

A PYELOGRAPHIC STUDY IN NORMAL WOMEN

HERMAN L. KRETSCHMER, M.D.

N. SPROAT HEANEY, M.D.

AND

EUGENE A. OKULY, M.D.

CHICAGO

In 1925 we¹ reported our observations on dilatation of the ureter and kidney pelvis during pregnancy in a group of cases studied by retrograde pyelography. The cases were divided into three groups.

In group 1 were eleven cases of acute pyelitis during pregnancy. In every case either bilateral or unilateral dilatation was found of from marked to enormous degree.

Group 2 consisted of nineteen cases of normal pregnancy with normal urine. In sixteen of these cases, or 84.16 per cent, either unilateral or bilateral dilatation was found.

In group 3 were six patients who gave a history of a pyelitis either before marriage or during a previous pregnancy but who were normal at the time of the investigation. Bilateral dilatation was found in two cases, unilateral in three cases and no dilatation in one case. The conclusion was reached that varying degrees of dilatation occur in approximately 80 per cent of cases of normal pregnancy.

Seng² studied a series of seventy-eight normal pregnant women by retrograde pyelography and found that 100 per cent showed dilatation of the right ureter and 94.5 per cent showed right hydronephrosis while the left ureter showed dilatation in 66 per cent of primiparas and 77 per cent of multiparas and left hydronephrosis in 46 per cent of primiparas and 66 per cent of multiparas.

Schumacher³ studied 100 pregnancies by intravenous pyelography. He found that dilatation of the lumbar ureter occurred in 100 per cent of cases after the fifth month and increased with the duration of pregnancy, and that bilateral dilatation of the lumbar ureter occurred in 83 per cent of cases. He found dilatation of the pelvic ureter in only two cases. He found twist-

Fig. 1—Moderate dilatation of the right kidney pelvis and slight clubbing of the calices in Mrs. S. at fourth month of pregnancy.

ing of the upper third of the ureter in 80 per cent of the cases and attributed the conditions to obstruction.

Cornell and Warfield⁴ in a similar study found dilatation of the right ureter in every case examined, beginning as early as the fifth month.

In order to verify our previous observations and conclusions, we undertook to study another series of cases by intravenous pyelography, expecting that we might find in this series fewer dilatations, since we suspected that possibly overdistention of the ureter and kidney pelvis by the retrograde method might have increased the percentage of dilatations in our first study.

For this investigation we selected only such women as gave normal previous kidney and bladder histories and who were normal as to urinary examinations and obstetric conditions at the time the study of each case was begun. We not only wished to determine how commonly dilatation of the kidney pelvis and ureter occurs during pregnancy but were curious regarding several other questions, namely, How early on the average does the dilatation begin and does it always increase as pregnancy lengthens? Does the dilatation, when present, start to disappear immediately after delivery, and how long after delivery does it require for

the normal conditions to return? With these questions in mind, we decided to assume the study of only such cases as we could probably follow throughout pregnancy and the puerperium, expecting to make examinations first between the second and fifth months, then during the seventh or eighth month or just before delivery, then between the eighth and fourteenth days post partum, again six weeks after delivery, and finally about three or four months post partum, should the last previous examination not already be normal.

Neoskiodan was the drug selected for this study. Twenty cubic centimeters was injected into the cubital vein and the first films were made ten minutes after the injection, and the second films taken from twenty to forty minutes after the first films were made. Only one patient showed any idiosyncrasy for the drug. She vomited each time after the injection but had no febrile reaction.

In all, the study of fifty-nine cases was begun. Five of these were discarded after the first intravenous pyelogram was made because the urine examined bacteriologically was found to show a few colon bacilli and the sediment to show a few leukocytes, leaving a series of fifty-four normal cases for further study on whom intravenous pyelograms were made between the second and fifth months. Ten of these patients failed to return, so that forty-four patients were studied.

Fig. 2—Massive right hydronephrosis and dilatation of the right ureter and moderate dilatation of the left kidney pelvis and kinking of the left ureter with fetal long bones overlying the right kidney pelvis, in Mrs. S. at term.

between the sixth and eighth months. Some of these patients have not yet been delivered while others have been delivered so recently that their complete study has not been finished. There are, however, thirty-one cases

that have been followed from early pregnancy through the delivery and puerperium until the kidney and ureteral conditions were normal

ANALYSIS

The youngest woman was 17 years of age and the oldest was 37. In this group there were thirty-five primiparas and nineteen multiparas

Fig 3—Decrease in the size of the right hydronephrosis with some increase in the dilatation of the left kidney pelvis and blunting of the calices and dilatation and tortuosity of both ureters in Mrs S two days post partum

First Period—This part of the study lay between the second and fifth months. Fifty-four cases were studied and there was evidence of dilatation in 67 per cent

TABLE 1—Analysis of the Distribution of the Dilatation in First Period

Calices on right side	57.0 per cent
Calices on left side	15.0 per cent
Pelvis on right side	54.0 per cent
Pelvis on left side	15.5 per cent
Lumbar ureter on right side	2.0 per cent
Lumbar ureter on left side	5.0 per cent
Pelvic ureter on right side	1.7 per cent
Pelvic ureter on left side	3.4 per cent

The dilatation was distributed as follows: right and left sides, 37.0 per cent; right side only, 28.3 per cent; left side only, 1.7 per cent

The earliest case was examined at two months and showed dilatation of the right pelvis and calices with kinking of the right ureter and the left side was normal. An analysis of the distribution of the dilatation is given in table 1

Second Period—This period of study lay between the sixth and ninth months. Forty-four cases were studied during this period and 93 per cent showed dilatation, an increase of 26 per cent over the first period. The dilatation was distributed as follows:

right and left side, 54.7 per cent; right side only, 38.3 per cent; left side only, none. An analysis of the distribution of the dilatation is shown in table 2

Third Period—This period of study was in the early puerperium, that is, during the first two weeks after delivery. In this group there were thirty-two cases. In 59.375 per cent the pyelograms showed a return to normal after two weeks. In 34.375 per cent the pyelograms were normal after six weeks and the remaining 6.250 per cent were normal after twelve weeks

TABLE 2—Analysis of the Distribution of the Dilatation in the Second Period

Calices on right side	92.00 per cent
Calices on left side	30.70 per cent
Pelvis on right side	86.15 per cent
Pelvis on left side	30.70 per cent
Lumbar ureter on right side	74.60 per cent
Lumbar ureter on left side	50.00 per cent
Pelvic ureters	Not visible

Fourth Period—The fourth period of study included those cases that were not normal at the end of the two weeks and were studied between the sixth and tenth weeks post partum

Fig 4—Further decrease in the size of the right hydronephrosis with normal pyelogram and ureterogram on the left in Mrs S six weeks post partum

Although 93 per cent showed some dilatation during the sixth to the ninth month of pregnancy, 4.6 per cent of these forty-four women who previously showed dilatation between the second and fifth month were found to be normal during the sixth to the ninth month, so that some time during pregnancy dilatation was found in 97.6 per cent

Only one patient (2.4 per cent) in this series failed to show dilatation at some period during pregnancy and she was a primipara who had twins. However, she did show a mild dilatation of the calices and lumbar ureter on the left side ten days after delivery. Twenty-one days after delivery the calices had returned to normal and the dilatation of the ureter had decreased 50 per cent, at the end of seven weeks she was normal.

In this series of cases, therefore, 100 per cent showed evidence of dilatation at some time during pregnancy or after delivery.

DEGREES OF DILATATION

For purposes of comparison, we graded the degrees of dilatation from 1 to 6. On the average the dilatation found between the second and fifth months increased in size between the sixth and ninth months.

As previously stated, 4.6 per cent of the dilatations found between the second and fifth months showed no dilatation between the sixth and ninth months. Between the second and fifth months 4.6 per cent of the dilatations remained stationary as the pregnancy advanced, 90.8 per cent of cases showed a progressive increase in the dilatation, some of them up to six times the amount of dilatation seen early in pregnancy. Some trouble was met in the interpretation of a few films because of obscurity caused by the fetal parts overlying the urinary system.

LATERAL DISPLACEMENT OF LUMBAR URETER

As this study progressed, we were impressed by the frequency with which lateral displacement of the lumbar ureter was found. From the second to the fifth month the following displacements were noted: bilateral displacement 12.95 per cent, displacement of the right ureter only 7.40 per cent and displacement of the left ureter only 5.55 per cent, making a total of 25.90 per cent.

As the pregnancy advanced the number of cases showing displacement increased, so that from the sixth to the ninth month the following incidence was noted: bilateral displacement 24.97 per cent, displacement of the right ureter only 22.60 per cent and displacement of the left ureter only 13.56 per cent, making a total of 61.13 per cent.

Mesial displacement of the right ureter was found in three cases between the second and fifth months and in two cases on the left side, while between the sixth and ninth months only one mesial displacement of the ureter was found and that was on the right side.

The ureters that were mesially displaced between the second and fifth months became laterally displaced between the sixth and ninth months, except in one case in which the right ureter remained mesially displaced.

Outward displacement of the ureter increased as pregnancy advanced, except in one case in which it was less.

PELVIC URETER

The pelvic ureter was visible between the second and fifth months in 23.2 per cent on the right side and in 37.2 per cent on the left side. Only one case showed dilatation, and this was on the left side.

Between the sixth and ninth months the visibility of the right ureter was 9.3 per cent and the left 20.9 per cent. There was no evidence of dilatation. In the case that showed dilatation between the second and fifth months, the dilatation was not visible between the sixth and ninth months.

After delivery the pelvic ureter was visible on the right side in 61.5 per cent and on the left side in 51

per cent. Only one case showed dilatation and that on the right side, along with dilatation of the lumbar ureter.

GENITO-URINARY ANOMALIES

In this group of fifty-nine cases in which pyelograms were made, the following malformations were found: bifid pelvis, two cases, double kidney and complete double ureter (left), two cases, and bilateral double pelvis, double kidney (left), one case. In one of the cases of complete double kidney and ureter the upper half remained normal while the lower half showed marked dilatation of the pelvis and ureter.

SUMMARY

1 Dilatation of ureters and kidney pelves occurred in 100 per cent of our cases during pregnancy or the puerperium.

2 The striking feature about the dilatation of the ureter during pregnancy is that the dilatation is almost universally above the brim of the pelvis.

3 As a rule, the dilatation is progressive along with pregnancy. There was one exception to this statement in which case the ureter was normal in advanced pregnancy when earlier it was dilated.

4 Lateral displacement of the ureter, when found early in pregnancy, tends to increase as the pregnancy advances.

5 In none of these cases did pyelitis develop during pregnancy, although marked dilatation and lateral displacement were present.

6 Presentation and position of the fetus could not be brought into causative relationship with dilatation or displacement.

ABSTRACT OF DISCUSSION

ON PAPERS OF DRs RANDALL AND MURRAY AND DRs KRETSCHMER, HEANEY AND OCKULY

Dr. F. H. GALLS, Chicago. I have been interested in this subject since I did some work on pyelitis in 1922, particularly the question of dilatation of the ureters in pyelitis and the subsequent contraction that occurs. I wish to raise the question as to why the ureters dilate and why they recover so rapidly in most instances after delivery. It has occurred to me that it is possible that the dilatation may be due to some substance in the blood which inhibits the smooth muscle contraction. There is something in the blood of the pregnant woman that prevents the uterus normally from emptying itself until the fetus is at term. When the time comes, the uterus starts to deliver itself. During the distention of the uterus and while its ability to contract is inhibited there is distention also of the ureters, and when the uterus empties itself the ureters also contract. Both the uterus and the ureters are made of smooth muscle and are developed embryologically from similar tissue, and are controlled by a similar nervous mechanism. In regard to the observation of deviation of the ureter which Drs. Kretschmer, Heaney and Ockuly brought out I wish to ask whether the position and rotation of the uterus were noted. Any one who has done cesarean sections has noted marked deviation and rotation of the uterus. When examining the uterus early in pregnancy one often finds that the two sides of the uterus do not enlarge at the same rate. Frequently the uterus is not pear shaped but is larger on one side than on the other. Embryologically the uterus is a bicornate organ and early in pregnancy the side containing the pregnancy enlarges first. The asymmetrical development may account for the deviation of the ureter early and the rotation of the uterus increases the deviation as pregnancy advances. In connection with work on pyelitis I examined a number of normal women post partum to see how many had residual urine containing bacteria. Practically 80 per cent had residual urine and most of them had staphylococci and *B. coli* in the urine. So it seems that the danger of introducing other organisms by careful use of the catheter may be overemphasized. I agree with

Drs Randall and Murray that women suffering from retention of urine should be relieved. Those who do many perineorrhaphies frequently notice the retention following perineorrhaphy. I frequently note this complication, although there is no injury or irritation to the floor of the bladder. I feel that retention in these cases is due to a reflex inhibition of the sphincter.

DR VINCENT J O'CONNOR, Chicago. As has been illustrated this morning excretory urography enables one to demonstrate dilatation of the ureters and renal pelvis during pregnancy in a large majority of instances. These studies afford further and added proof of the accuracy of the work of Hofbauer and others that pregnancy is accompanied by the frequent occurrence of ureteral dilatation and, consequent on it, a degree of ureteral atony and a delay in ureteral action. Hofbauer has shown that during pregnancy the lower end of the ureter and the trigon undergo hypertrophic changes in the musculature, associated with hyperplastic changes in the connective tissue with resultant narrowing of the lower part of the pelvic portion of the ureter. These changes are frequent enough to be designated as "physiologic" and can in no way be satisfactorily explained by the time honored theory of ureteral pressure from the enlarged uterus or the pressure of the fetal head. Histologic evidence suggests an analogy between these processes in the ureter and the trigon, with the involution phenomenon occurring in the uterus during the puerperium. In the presence of urinary infection during pregnancy, this ureteral stasis and added narrowing may favor the development of permanent sclerotic changes in the ureteral wall with a continuation of inadequate drainage and recurrent infection. Clinically, one sees rather frequently women who have never had a urinary infection before pregnancy but who continue to have renal infection and backache unless relieved by ureteral dilation. On the other hand, one sees in even greater number the women with pyelitis during pregnancy whose ureteral activity is normally restored shortly after the puerperium. As clinicians, it seems idle for us to argue back and forth as we have done in the past, as to whether these individuals had preexisting ureteral obstruction as the cause of their faulty drainage and infection or whether they had pyelitis in infancy and so forth. The important point is to regard any woman who has urinary infection during pregnancy as demanding follow-up observation of the ureteral dynamics, after the puerperium has terminated. In this way those patients with persistent obstruction may be treated before marked upper urinary tract damage has occurred and those in whom normal function has been restored may be dismissed with the knowledge that the normal cycle has been completed. Whether excess of bile salts in the blood or insufficient pituitary or suprarenal secretion comprises the underlying 'physiologic' reasons for these changes during pregnancy remains to be proved. The discussion of Drs Randall and Murray on the care of the postpartum bladder is excellent proof of the dicta of Dr Hugh Cabot in his oft repeated pleas for the prompt and sane use of the urethral catheter. If this teaching should be followed there would be a decreased necessity for later urologic care in these patients.

DR WILLIAM E STEVENS, San Francisco. Various investigators estimate that dilatation of the kidney pelvis and ureters occurs in from 80 to 100 per cent of all pregnant women. The latter figure is more nearly correct. Schumacher, Mengert and Lee and Hodges studying in all 148 cases by means of excretory or retrograde urography found as did Kretschmer and his co-workers that dilatation occurs in every case. Dilatation like pyelitis during pregnancy is more common and more pronounced on the right side. A diagnosis of pyelitis of pregnancy was made in 106 or 13 per cent of 8118 cases of pregnancy seen in the department of gynecology and obstetrics at Stanford University School of Medicine. In a study of 225 cases of pyelitis of pregnancy treated in the Stanford service or reported in the literature I found that the right kidney was involved in 1-2 cases, the left in twenty six and both kidneys in forty six. About 18 per cent of our pyelitis cases that were associated with pregnancy occurred post partum. Dilatation of the upper urinary tract was seen in all of a small series of the cases in which pyelograms were taken. Opinions vary widely as to the etiologic factors in dilatation

of the kidney pelvis and ureters during pregnancy. Some believe that the latter is due to pressure of the enlarged uterus on the ureter, others because of obstruction of the ureters due to stretching, torsion and traction. Hofbauer states that the dilatation is due to the obstruction caused by the fibrosis and muscular hypertrophy that occur in the lower ends of the ureters during pregnancy. Ureteral and urethral strictures plus the congestion of the pelvic organs associated with pregnancy may be responsible for dilatation, stasis and subsequent pyelitis especially in the presence of an antepartum low grade infection. It is well recognized that very little pressure is necessary to obliterate the lumen of the ureter. The frequency with which dilatation of the ureter extends upward from the pelvic brim in cases of pregnancy lends weight to the conclusion that distention is often due to pressure of the uterus on the ureter at the brim of the pelvis. The position of the fetus and pressure by the uterus are etiologic factors in the dilatation of the ureters and pelvis during pregnancy. Most urologists will agree with Drs Randall and Murray that postpartum infection of the urinary tract is more common in the presence of residual urine plus overdistention. Other factors also have an influence in producing infection of the postpartum bladder. Following catheterization, two days after delivery, I found residual urine in twenty-nine, or 81 per cent, of thirty-six cases. Evidence of infection was absent in the majority. Residual urine alone without overdistention or other contributory factors probably has very little influence in producing infection.

DR G C PRATHER, Boston. At the Boston Lying-In Hospital, where we have about 2,000 deliveries a year, investigation shows that we have about 3 per cent who fail to void normally post partum. In 1929 I reported a system of intermittent drainage or constant drainage, or a combination of the two in the treatment of these atonic bladders, being especially careful to avoid overdistention of a bladder residual in those having urinary tract infections. I believe that such factors are responsible for certain cases of postpartum pyelitis. Since that time our figures show that in 192 cases of bladder complications post partum, during 1930-1932, there were only six in which pyelitis developed. This incidence of pyelitis is better than the series I reported in 1929 in which there were eight cases of postpartum pyelitis in fifty-eight cases of postpartum bladder complication. The methods of treatment now are essentially the same as those recommended in 1929, so the only conclusion to be drawn is that the house staff is more alert in recognizing these bladder complications and in giving them prompt treatment.

DR N S HEANEY, Chicago. There are some points that I wish to emphasize. The first is the preponderance of right-sided dilatation. During the fourth and fifth month the right side is dilated in 28 per cent and the left side in only 6 per cent of these cases. From the sixth to the ninth month the right side is dilated in 38 per cent and the left side in a low percentage. The work that has been done has left much to be explained. Why does the right side show this marked dilatation? Certainly it is not due to hypertrophy. Hyperplasia and hypertrophy (Hofbauer's theory) occurs at the vesico-ureteral junction and it decreases as one ascends the ureter. We found the pelvic ureter dilated in only one case while the lumbar ureter was dilated in many cases. If the hypertrophy is a factor the dilatation should begin at the vesico-ureteral junction and since hyperplasia and hypertrophy are the same in the two ureters the dilatation should be the same on the two sides but it is found thirty eight times on the right to one on the left. The frequency of right sided pyelitis over left sided pyelitis agrees with the increased frequency on the right side of dilatation and dilatation without a doubt others to the contrary is the factor of importance in the etiology of pyelitis.

DR L M RANDALL, Rochester, Minn. I should like to emphasize again the value of a definite routine in the care of the bladder in the puerperium. Without this one has to depend considerably on the patient's complaint of discomfort and inability to void and by the time this complaint is made overdistention may have occurred. We have found since the institution of a definite routine that our bladder complications during puerperium have been reduced to a minimum.

URETHROCYSTOGRAPHY IN THE MALE

JOSEPH A. HYAMS, MD
HERBERT R. KENYON, MD
AND
SAMUEL E. KRAMER, MD
NEW YORK

The lower urinary tract has been the subject of intensive investigation for the past decade, during which notable advances have been made particularly in the field of instrumental diagnosis and treatment. With increasing application, certain limitations of these procedures became apparent indicating the need for a supplementary method by which a clearer conception of form and function could be obtained. Urethrocystography fulfills this need and should be used as a part of the routine examination of patients presenting certain lesions of these organs.

Although, in our hands, urethrography has proved a valuable diagnostic procedure, its scope is limited as it fails to demonstrate pathologic conditions other than those confined to the urethra and its adnexa. Cystography, while more extensively employed and better understood, also has its limitations. Because of the close anatomic and functional relationship of the pos-

delineation than from urethrography or cystography alone. Previous experience with these two methods enabled us to develop a technic for the performance of urethrocystography by combining several procedures previously advocated by other workers with a simplified manometrically controlled syringe devised by us. Our early work convinced us that manometric control adds greatly to the accuracy and value of the procedure,

Fig. 1—Asepto syringe with by pass leading to air chamber trap and manometer

terior urethra, adnexa, vesical neck and bladder muscle, a more accurate concept of their morphology and function can be obtained by their simultaneous and complete

Fig. 2—Normal urethrocystogram oblique view. Anatomic landmarks and sphincteric contours clearly defined. Verumontanum demonstrated as a negative shadow.

minimizing its dangers and aiding in the duplication of observations on repeated examinations. The types of apparatus previously introduced are too cumbersome for routine use and on this account have been discarded by many workers.

Our syringe (fig. 1) possesses all the essential elements of a pressure apparatus. It consists of a two ounce Beckton Dickinson Asepto syringe modified by the inclusion of a by-pass and trap which prevents the flow of the medium into the manometer and renders possible the retention of all the advantages of manometric control while employing a simple syringe technic.

The complete and simultaneous delineation of the lower urinary tract by this technic provides a valuable supplement to the usual methods of diagnosis, and in certain instances in which instrumentation is impossible, undesirable or contraindicated, urethrocystography delineates the nature of the lesion and indicates the choice and extent of operative measures.

CONTRAST MEDIUMS

Solutions in the concentrations ordinarily employed in cystography are usually too radiopaque and may obscure smaller intruding masses and the outline of the bladder base when used for urethrocystography. We prefer a 3 per cent solution of sodium iodide, although in bladders of large capacity a 2 per cent solution is sufficient. Various substances have been advocated

From the Department of Urology, New York Post Graduate Medical School and Hospital, Columbia University.
Read before the Section on Urology at the Eighty-Fourth Annual Session of the American Medical Association, Milwaukee, June 14, 1933.
This work has been carried out through the courtesy of Dr. J. F. McCarthy, director of the Department of Urology at New York Post Graduate Medical School and Hospital, Columbia University.

for urethral delineation. We believe that any solutions used for this purpose should be nonirritating, sufficiently radiopaque, sterilizable, nontoxic, miscible with urine, and harmless if introduced into the circulation. The preparations of iodized oils do not fulfil all these requirements. The various compounds used for intravenous urography are ideal but too expensive for routine use. Simple solutions of sodium iodide in concentrations sufficient to give shadows of adequate density cause irritation. In our experience, equal proportions of a 20 per cent solution of skiodan and a solution consisting of sodium iodide 17.5 per cent, sodium bicarbonate 2 per cent and gelatin 1 per cent provide a medium adequate for ordinary use. Increasing the proportion of skiodan obviates any tendency toward irritation. The fact that the use of improper solutions may give rise to chemical urethritis of varying grades of severity and duration should be borne in mind.

TECHNIC

The patient is placed on an x-ray table equipped with a Bucky diaphragm. A small catheter is gently introduced under careful asepsis, the bladder capacity estimated with sterile water and a quantity of the 3 per cent solution of sodium iodide slightly less than the estimated capacity is introduced through the catheter, which is then withdrawn. Gentleness of instrumentation is important as it promotes relaxation and gains the cooperation of the patient. After trying the various positions, we have come to the conclusion that the oblique and anteroposterior positions are most satisfactory. During the first exposure the patient is placed

Fig 3—Pneumocystogram of posterior vesical lip two and one half years following nephrectomy for calculus pyelonephrosis showing associated posterior urethritis, prostatic and elevation of bladder base. Contracted bladder and ureteral remnant also demonstrated. Anteroposterior view.

obliquely on the table with the under thigh flexed and the upper thigh extended. This posture is maintained by the patient or if he is unable to retain this position he is supported by sand bags. The penis is extended below and parallel to the flexed thigh and the urethral contrast solution injected through the meatus the

manometrically controlled syringe providing a safeguard against the use of excessive force. The total quantity of fluid used for urethral distention is approximately 50 to 70 cc. Elaborate methods designed to prevent leakage are unnecessary, as adequate apposition of the bluntly tapered syringe tip and the meatus can be maintained by simple digital pressure. The use of oily solutions increases the possibility of leakage.

Fig 4—Oblique view of inflammatory stricture at bulbomembranous junction. Glands of Littre deformity of bulb tortuous nature of the stricture and irregularly dilated membranous urethra demonstrated.

The tube is focused on the lower portion of the symphysis pubis and inclined toward the head at an angle of 5 degrees. The x-ray exposure is made as the fluid is flowing freely into the bladder. Should the flow be impeded, the patient is instructed to void as the exposure is made. In the exceptional case in which the bladder cannot be entered because of impassable obstruction, the bladder contents may be rendered opaque by the intravenous use of a contrast substance, after which the urethra can be filled in the ordinary manner. A second film is exposed with the patient in the dorsal position the legs extended and the penis drawn down between the thighs. The best roentgenograms are obtained by using an x-ray apparatus of the greatest penetration, thus diminishing the time of exposure.

The statement has been made by Ledoux-Lebard and his associates¹ that the injection pressure should not exceed 300 mm of mercury. Ordinarily the pressure does not exceed from 150 to 160 mm and we have found it unnecessary to go above 220 mm. A drop in pressure of from 10 to 20 mm is usually noted as the external sphincter relaxes. Pressures exceeding 200 mm of mercury suggest the possibility of traumatic spasm or lack of cooperation on the part of the patient which may prevent satisfactory filling of the posterior urethra. Should this occur the procedure must be interrupted the patient reassured and the injection cautiously continued. Excessive pressures may result in

1. Ledoux-Lebard R, Garcia Calieron I, and Peletun J. J. Urethrographie. Paris: med. 1, 10, 111 (Feb. 6), 1932. X-Ray Exploration of Male Urethra. J. de radiol. et d'electrol. 15: 473-476 (Sept.) 1931.

mucosal injury and, when this occurs in the bulb, the contrast material may enter directly into the vascular system, owing to the intimate relationship of the vessels to the mucosa in this region. In our experience this has occurred only in cases of urethral stricture involving the bulbomembranous junction in which recent instrumentation had been attempted and manometric control was not employed. This efflux may take the form of a slight extravasation with entrance of the contrast solution into a few small vessels, or it may be sufficiently extensive to delineate the venous channels of the corpora cavernosa and the entire pelvic and gluteal regions (fig 5). Although we have not observed any constitutional reaction or permanent ill effects following urethrovenous injection, its occurrence emphasizes the necessity of employing innocuous solutions. Following instrumental exploration of the canal, an opportunity should be afforded for the traumatized urethral areas to heal before urethrocytography is performed. Furthermore, should both roentgenographic and instrumental investigation be contemplated at one sitting, the former should precede other intra-urethral manipulations. Injections of contrast mediums are contraindicated in the presence of acute infections, active inflammations and recent extensive injuries.

INTERPRETATIONS OF URETHROCYSTOGRAMS

The outlines of the normal urethra (fig 2) are sharply defined and regular, and the contour is symmetrical. The caliber varies with the anatomic areas

Fig 5—Urethrovascular injection in a patient with impassable stricture showing a widespread escape of medium into the venous chain draining into the internal pudendal and hypogastric veins. No manometric control.

of narrowing and dilatation, is widest at the bulb, and diminishes markedly as the membranous urethra is approached. The shadow of the bulb in the oblique view possesses a characteristic onion-shaped appearance, while the tortuous contour of this region in the anteroposterior film is the result of superimposition of shadows. The membranous urethra, in both antero-

posterior and oblique films, is represented as a narrow pyramid with the base situated distally. The posterior urethral shadow is narrower than that of the anterior urethra, is fusiform, and is widest at its midportion. The verumontanum may produce an elliptic area of decreased density in the anteroposterior film or a filling defect on the urethral floor in the oblique view. In the anteroposterior position the posterior urethral shadow

Fig 6—Prostatic enlargement. Oblique exposure showing distortion and angulation of posterior urethra; patent prostatic ducts displaced and widely open; internal meatus. Marked intra-urethral encroachment and moderate intravesical intrusion demonstrated. Note irregularly dilated bladder with numerous sacculations.

lies between the two pubic bones and terminates at right angles to the bladder base. The bladder has the usual circular or oval contour, with the inferior border parallel to the upper margin of the pubes. In oblique films the urethral shadow overlies the pubic ramus and merges with that of the bladder at an obtuse angle. The curve of the bladder base is larger and more gradual than in the anteroposterior view.

Advanced chronic urethritis is manifested by fairly definite changes. In the anterior urethra those most frequently noted are irregularities of outline and caliber, resulting in a characteristic undulatory appearance of the urethral margins, while the glands of Littre or accessory pockets are demonstrable at times in the oblique view. There may be either dilatation due to atonicity of the walls or loss of the normal dilatability because of infiltration and spasm in the posterior urethra. The internal sphincter and bladder base show no deviation from the normal.

When concomitant adnexal disease is present, the prostatic and ejaculatory ducts are frequently delineated and occasionally the injected medium may be discernible in the seminal vesicles, Cowper's glands and para-urethral pockets. This demonstration of the accessory urethral structures is of diagnostic importance. Our experience confirms the observations of Langer² that normal adnexal structures do not readily permit

2 Langer E. Roentgenography of the Male Urethra. *Venerol. Dermat.* 6:36-40 (May) 1929. Pulmonary Embolism from the Use of Iodized Oil in Urethrography. *Roentgenpraxis* 4:405-406 (May) 1932. (Comment on article of Eichler P. Pulmonary Embolism from Use of Iodized Oil. *ibid.* 4:138-140 [Feb. 1] 1932). *Die Roentgendagnostik der männlichen Harnröhre*. Leipzig 1931.

entrance of the injected fluid. Flattening of the bladder base and irregularities in its contour may be present, depending on the extent and severity of prostatic involvement.

In advanced prefibrosis of the posterior vesical lip (fig 3) the appearances are those accompanying chronic urethritis with adnexal involvement plus sphincteric irregularities and alterations in the angle of entry of the urethra into the bladder. Changes in contour and regularity of the bladder shadow, if present, are proportionate to the degree of obstruction. While the urethrocytographic changes are often sufficiently characteristic to indicate the nature of these inflammatory lesions, confirmation by clinical and cysto-urethroscopic examinations is desirable.

STRICTURE OF THE URETHRA

The use of the micturitional method for the delineation of stricture is unsatisfactory for, although the proximal portion of the urethra can be outlined, visualization of the constricted area and the distal portion of the urethra may be incomplete. Simple anterior injections do not adequately delineate the urethral lumen proximal to the site of constriction. The combined method clearly depicts the nature of the obstruction and the secondary urethral (fig 4) and bladder changes and is particularly applicable to patients with strictures of small caliber in whom instrumentation is difficult, who present fistulas, or on whom previous operations have been performed. Changes characteristic of chronic inflammation may be present in the

Fig 7.—Moderate intra-urethral and intravesical prostatic enlargement. Few associated changes.

anterior urethra or its accessory glands (fig 4) and false passages may be visible. The most frequent location of constriction of the inflammatory type is at the bulbomembranous junction and the bulb is frequently deformed. Traumatic strictures may occur at any site. The degree of involvement and the character of the lumen in the constricted zone are well delineated. Indications of pathologic changes in the posterior urethra

characterized by irregularly dilated segments are frequently seen and the adnexal passages may be visualized when actually involved. Deformities of the vesical sphincter, the bladder base and the bladder itself, as well as diverticula and vesicorenal reflux, are demonstrated when present. Both views are essential for the complete delineation of the extent of the stricture and all complicating disturbances. Urethrocytography plays

Fig 8.—Prostatic enlargement. Apparent increase in anteroposterior diameter of prostatic urethra. Forward angulation at vesical neck, intra-urethral encroachment and marked intravesical intrusion demonstrated.

an important role in this field, both as a supplementary and as an independent method of diagnosis, and it also provides a graphic record of the progress of these cases.

ENLARGEMENT OF THE PROSTATE

There are no characteristic changes in the anterior urethra, bulb or external sphincter in prostatic enlargement. The spindle-shaped contour of the posterior urethra is altered in the presence of encroaching masses and the verumontanum may show evidences of lateral compression. The direction of the prostatic urethra may deviate laterally and anteroposteriorly, depending on the size and disposition of the prostatic lobes. Forward displacement of the supramontane portion of the prostatic urethra is a common finding in median lobe enlargements and, in the smaller types, may be the only discernible change. This distortion results in the loss of the normal obtuse angle of entry of the urethra into the bladder and is manifested as a Coude or bi-Coude deformity in the oblique view. Median lobe prostatic appearances similar to but less extensive than those caused by median lobes. In the lesser grades of vesical neck deformities the roentgenographic changes should be considered in conjunction with the data obtained from cysto-urethroscopy.

The internal sphincter may show no change. In the presence of large intravesical lobes or of intra-urethral encroachments that render the sphincter rigid the displaced internal meatus is widely open and shows evidence of distortion. Elevations and irregularities of the bladder base are proportionate to the degree of

intravesical prostatic intrusion. Any change in the bladder outline due to loss of elasticity, trabeculations, sacculations and diverticula is demonstrated. Concomitant tumors, calculi and vesicorenal reflux are readily demonstrable. The apparent increase in caliber of portions of the urethra, variations in density with the appearance of double columns of fluid and confusion as to the relative sizes and disposition of the various lobes may lead to errors of interpretation unless both planes of exposure are utilized (figs 6, 7 and 8).

Carcinoma of the prostate produces urethrocystographic deformities similar to but more irregular than those caused by benign enlargements. Filling defects and irregularities resulting from extensions involving the bladder wall may be shown. Although the diagnosis of prostatic enlargement is readily made by the usual methods of examination, urethrocystography definitely indicates the size of the enlargement and its relation to the urethra and the bladder, and gives a more accurate idea of the contour and location of projecting and overhanging intravesical intrusions than can be obtained by any other method. Such data enable the surgeon to adapt his operative procedure to the needs of the individual case and, in those cases in which endo-urethral resection is elected, provides an indication of the location and the amount of tissue to be removed.

OBSERVATIONS FOLLOWING OPERATIONS FOR VESICAL NECK OBSTRUCTIONS

Urethrocystography provides a graphic method of studying the results of operative procedures for the relief of vesical neck obstruction. Regardless of the surgical method employed, good results are characterized by the decrease or disappearance of obstructive manifestations. Following successful suprapubic enucleation, the sphincters are usually intact and, after an interval, the prostatic urethra tends to resume a normal contour. The distal portion of the verumontanum may be discernible. The appearance varies with the completeness of enucleation, degree of operative trauma to adjacent structures and other factors interfering with proper healing. Evidences of cavitation in the prostatic bed, diverticular pockets, atony or constrictions of the internal sphincter and irregularities in the lumen of the prostatic urethra are common observations in unsatisfactory cases. We have demonstrated injury of the external sphincter and membranous urethra, strictures involving the entire length of the prostatic urethra, and complete atresia of the urethral lumen following suprapubic prostatectomy.

Subsequent to the performance of endo-urethral resection, the extent to which the obstructions have been removed and the urethral contours restored can be accurately ascertained. Although adequate canalization may have been accomplished, deformity of the bladder base may persist as a result of the undisturbed intravesical portions of the gland. The nature and location of these remaining intrusions are shown in the urethrocystogram and any necessity for further resection is clearly demonstrated.

It is readily possible to ascertain the extent of involvement of the lower urinary tract in neurogenous disorders by means of urethrocystography. The condition of the bladder musculature (fig 9) and the functional capacity of the sphincters are well shown. The coexistence of *tabes dorsalis* and prostatic enlargement can be demonstrated by this method. Urethrocystography may prove of value as a graphic supplement to cystometric observations.

RECAPITULATION

Our purpose in this communication has been to call attention to the advantages of a diagnostic method that has the same applicability to lower urinary tract conditions as ureteropyelography has to those of the ureter and the kidney. Just as the latter procedure must be used in conjunction with cystoscopic and other observations, urethrocystography must be supplemented by observations derived from all sources. The statements made in the preceding portion of this presentation are therefore, based on combined roentgen, instrumental and clinical studies during the past two years.

The successful employment of this procedure depends on the establishment of a simple but definitely standardized technic. The syringe and the method developed by us are presented as a means of accomplishing this object.

Fig. 9—*Tabes dorsalis* with vesical symptoms but without incontinence

We have adopted the use of watery solutions because in addition to fulfilling all the requirements of a satisfactory medium, they penetrate readily into the smaller canals and pockets. Iodized oils do not possess these advantages. Their use may be attended by danger if a considerable quantity is introduced into the circulation, as the result of urethrovascular injection. We have at different times employed solutions of various types and concentrations and at present are convinced that eventually aqueous solutions will be found best suited for this purpose.

The combined method has adequately demonstrated bladder, urethral and adnexal changes and has proved less expensive, less time consuming and more satisfactory as a routine diagnostic method than urethrography or cystography as individual procedures.

CONCLUSIONS

- 1 With careful technic and innocuous solutions, urethrocystography is harmless.
- 2 Aqueous contrast mediums are advocated.
- 3 Gentleness in manipulations and avoidance of excessive pressure are essential.

4 Manometric control is recommended and a syringe for this purpose is presented

5 The possibility of urethrovascular injection exists regardless of the type of solution used and precautions should be exercised to minimize its occurrence

6 Urethrocytography is a valuable diagnostic method and should be employed in the routine examination of patients with disorders of the lower urinary tract

7 Urethrocytograms provide a graphic record of the progress of each case. They aid the surgeon in the selection of operative procedures and in evaluating the final results

78 East Seventy-Ninth Street

ABSTRACT OF DISCUSSION

DR M A NICHOLSON Duluth Minn The idea of using both cystogram and urethrogram in the same picture originated with Dr Hyams and his associates. Their method differs somewhat from mine. My pictures were all made with iodized oil. These urethrograms illustrate the fact that the oil solution penetrates into the finest ducts and through threadlike strictures. The patients have not the slightest discomfort with its use and its cost will compare favorably with the intravenous dyes as it may be diluted from 50 to 60 per cent. Many have questioned whether this procedure has practical value. In one case a man for seven years passed urine through a fistula in the scrotum. I was unable to pass anything down the anterior urethra except a very fine filiform bougie. An anterior urethrogram showed multiple strictures of the urethra. The sinus was dissected out and a new urethra constructed, to the great satisfaction of the patient. I think this case demonstrates the practical value of urethrography.

DR ROBERT GUTIERREZ New York Dr Hyams and his collaborators made an appeal for urethrocytography and I feel strongly that this should be a routine method of examination particularly when there are conditions that cannot be revealed by other methods and it is essential to establish an accurate diagnosis before operation. Urethrocytography has served to emphasize the fact that intravenous urography does not entirely solve the problem of establishing a correct diagnosis; it does not assist in discovering pathologic lesions affecting the lower part of the urinary tract. Some years ago Dr Lowsley and I reported six cases of diverticula of the urethra. At this time I collected and tabulated from the literature 116 cases. I was amazed to see that over 50 per cent of them were not properly diagnosed but were found post mortem or at the operating table. In but few cases was the diagnosis made before the operation by the use of urethrograms as in the cases that we reported. Certain points of interest that we stressed in our paper are worth bringing up at this time: namely that the urethrogram should be made by injecting the urethra and the bladder at the same time and that it should be taken at the time of micturition. Diverticula of the urethra acquired or congenital may be found in any part of the urethra but they are more commonly present in the prostatic urethra particularly after rupture of a prostatic abscess that has been entirely overlooked. In most of these cases surgical excision is the proper indication. A study of the literature has revealed that when diverticula of the membranous or prostatic urethra are present a resection has often resulted in a perineal fistula necessitating several operations. In order to obviate these complications we recommend diverting the urine from above by cystostomy previous to the operation. Thus the perineal wound is given a chance to heal by primary union and without complications. I may repeat that while intravenous urography is of great value one must bear in mind that it is not the key to all conditions encountered in modern urology and particularly in pathologic lesions affecting the lower urinary tract as the so-called incurable strictures, tumor, diverticula and other unrecognized conditions in which urethrograms are properly indicated in an effort to establish a correct diagnosis.

DR HARRY P LEE, Iowa City Last year Dr Alcock returned from the meeting of the American Medical Association enthusiastic over air cystograms. We recognized the dangers accompanying the air cystograms but nevertheless started doing them, and the pictures were so superior to the sodium iodide cystograms that we have continued doing them and have developed a technique of doing air cystograms in every prostatic case that is seen in the clinic. We have found that air cystograms are not very good in delineating diverticula of the bladder, so we take plain plates in order to eliminate any stones and then take an anteroposterior sodium iodide cystogram to show any diverticula. We found the air cystograms of great assistance but needed a new technique to visualize the prostatic urethra. The use of iodized oil in all cases in a clinic is very expensive, so Dr Flocks has had made up a jelly and incorporated in this iodized oil which gives a semiliquid material the consistency of which can be changed by adding any amount of water necessary. We then do a combined air cystogram and iodized oil jelly urethrogram with the patient at about a 45 degree angle and in this way visualize the prostate and the prostatic urethra. We have done more than 300 air cystograms and have had no trouble so far.

DR N G ALCOCK, Iowa City I am enthusiastic over urethrograms and do not know how I could get along in prostatic work without air cystograms and urethrograms. This gives us much more accurate information than cystoscopy does.

DR J A HYAMS New York The value of urethrocytography lies in the complete delineation of pathologic changes located in the urethra, adnexa or bladder. This film indicates the presence of a large tumor of the bladder wall, which overlies the right urethral opening. Above the filling defect caused by the tumor, the ureter is partially delineated by the reflux of the contrast medium. In his presentation, Dr Herbst emphasized the frequent association of diverticulum of the bladder with obstructive vesical neck changes. This method lends itself to a graphic demonstration of changes of this type. We agree with Dr Nicholson that urethrography has a definite place in the delineation of the lower part of the urinary tract but feel that its field is limited. In stricture of the urethra, our combined method is more advantageous than the urethrogram made by simple injection because it delineates not only the nature of the obstruction but the secondary urethral and bladder changes as well. The possibility of urethrovascular injection contraindicates the use of any contrast medium that fails to conform to the essential requirements previously detailed. The iodized oils, plain or combined with various vehicles, whether bland oils or jelly do not fulfil these requirements. The numerous reported accidents following air distention of the bladder and urethra contraindicate its routine use, particularly when innocuous mediums are available. We wish to stress the need of gentleness, controlled pressure and the use of safe contrast solutions and to emphasize the fact that urethrocytograms delineate not only surface but subsurface changes as well.

The Proof of a Drug's Efficacy—It seems unbelievable that the profession can long continue tolerant of a system under which drugs and other remedial measures are vaunted on an inadequate basis of recorded experience, or that doctors should be almost forced by popular clamor to give and to transfer allegiance, an allegiance stimulated by report of advertisement and not by proved worth temporarily to this remedy or to that. It is not through error but often fallacious general impressions that full progress is to be expected but mainly through deliberate unbiased and untiring study of the reactions of patients to given remedies. It is the duty of clinical science in this branch of its activity to maintain close linkage with pharmacology but it is equally its duty clearly to recognize that so far as both manner and intensity are concerned the action of a drug on man is not necessarily the same as the action on an animal and that the action on the diseased is not necessarily the same as on the healthy man. The proof or disproof of a drug's efficacy rests finally on the test in patients.—Lewis Thomas, *Clinical Science, Lancet* 2: 905 (Oct 21) 1933.

SKELETAL TRACTION IN TREATMENT OF FRACTURES OF SHAFT OF TIBIA AND FIBULA

W K WEST, MD
OKLAHOMA CITY

The most important points to be considered in the treatment of fractures of the tibia and fibula are

- First, general condition of the patient
- Second, extent of resulting permanent disability
- Third, length of temporary total disability
- Fourth, cost of medical care

In the consideration of these four major problems, I agree that the general condition of the patient is most important, but that phase of the subject cannot well be discussed here. Therefore, from a technical standpoint, the first real problem is the prevention of permanent partial disability. It should be the most important consideration, more important than the temporary total disability, with its resulting loss of time and loss of wages, also more important than the cost of medical care.

Provided as good results could be expected in all cases of severe fractures of the tibia and fibula as are expected in the cases of simple transverse fractures, a

ing the maximum degree of normal function. In the simple types of fractures of the tibia and fibula, either a molded plaster splint or a bivalved circular plaster bandage is sufficient and calls for no hospitalization beyond the incidence of reduction and application of fixation, but, unfortunately, severe multiple or comminuted fractures do not respond favorably to these

Fig. 1—Compound comminuted fracture of tibia and fibula treated by wire fixation above and below fracture. Patient able to leave the hospital within a few days.

circular bandage or the splint method of treatment would be far more practical than skeletal traction. But many factors arise to make the treatment of these severe cases very complicated and expensive in obtain-

Fig. 2—Fixed wire traction above and below fracture after reduction by weight traction.

simple measures. As a rule, fractures of the tibia and fibula, unless the case is of several or more days' duration, can be reduced, but the real difficulty is in maintaining reduction. Loss of bony contact results in angulation and overriding because of involuntary muscle spasm. In these severe cases, the swelling is very marked, and, as soon as the leg decreases in size, the appliance is too large, allows deformity to take place and permits changes in the relationship of the bone fragments.

Traction is the best means to combat tendencies to deformity. Lower leg skin traction has not proved to be very practical, especially in cases in which union is slow.

Skeletal traction has many advantages. Space will not permit the discussion of the other types of skeletal traction, such as the Steinmann pin, calipers, and the like. In all my cases the Kirschner wire technique has been used as follows:

1 Cases in which weight traction is used in conjunction with the Braun frame, as described by Boehler, the Kirschner wire being introduced through the middle of the os calcis, for example cases coming in several days after injury, also spiral or badly comminuted fractures.

2 Cases in which the wire is introduced through the os calcis and reduction carried out immediately, followed by the use of the long leg plaster bandage with the knee flexed. The wire and bow are incorporated in the cast. These cases are usually those in which the fractures are low in the tibia and fibula. A spinal or general anesthetic is used when a manual reduction is done at the time the wire is introduced.

3 Cases in which the fracture is in the middle or upper third. Two wires are placed, one just below the knee and the other just above the ankle. A cast is applied to the fracture site above and below, then with traction applied, the two casts are united by connecting plaster

In the first method it is necessary to hospitalize the patient for a sufficient time for reduction of the fracture and in some cases until there is considerable callus before the weight is released. The second and third methods enable the patients to be out of bed immediately, therefore hospitalization is usually unnecessary.

These methods are not new, as the principles of skeletal traction in fractures of the tibia and fibula have been described by many men, such as Conwell, White and Eikenbary.

In the first group of cases, skeletal wire traction in conjunction with the Braun frame, is used in cases

Fig. 3—Union twelve weeks after reduction

in which the fracture is of several days' duration or in cases in which it is thought best to maintain perfect alignment and still permit the leg to be inspected constantly. A local anesthetic is sufficient in this type of case. During the time this method is carried out it is necessary for the patient to remain in the hospital. As soon as the reduction is satisfactory and the general condition of the leg will permit a circular plaster bandage is applied with the wire and bow incorporated in the cast in the average case for a period of about two weeks.

In the next group of cases, comminuted fractures in the lower third and into the ankle joint may be treated by introducing the Kirschner wire through the os calcis, then by traction on the bow which is attached to the wire on each side the fracture may be reduced and with the knee in a slight flexion position and the foot at a right angle a circular plaster cast may be applied from the middle of the thigh to the tips of the toes incorporating the wire and bow in the cast. The cast may be split to allow for swelling and not interfere

with the wire fixation. At the end of from three to four weeks, the wire is removed at the time the cast is changed. This method holds the fragments satisfactorily and allows the patient to be on crutches and leave the hospital immediately.

In the third group of cases, in which the fractures are in the upper and middle third of the shaft, I have found it best to introduce two wires, one above the fracture and one below, the upper wire being placed about 3 inches below the knee and the lower about 1 inch above the ankle. Bows are attached to maintain tension in the wire. The plaster is applied from the groin down to the fracture line, incorporating the upper wire and bow. A cast is then applied from the tips of the toes to the fracture line, incorporating the lower wire and bow. Then, by manual traction, the fracture is reduced, and the upper and lower plasters are united.

Fractures seen within the first few hours are very satisfactorily reduced by this method. In these cases the patient may be on crutches within a few days and avoid the cost of hospital expense. In the majority of cases in which there is considerable comminution and in the multiple types as well, union is slow. By using this method, the fragments will be held accurately in spite of the fact that the leg will show the usual atrophy.

There has been some criticism of the use of skeletal traction because of the expense of bows, wires, wrenches, drills and the like. From my experience, I feel that in a considerable number of fractures, skeletal wire traction has no substitute. Undoubtedly, many cases that formerly went to open operation may be treated satisfactorily in this way. Therefore the equipment necessary should be obtained by any one who takes on the responsibility of caring for severe fracture cases.

In compound fractures, the fragments can be maintained in proper position by using either the wire weight traction or the two-wire fixed traction. A window may be cut in the cast and the wounds dressed when necessary without danger of the fragments slipping, because of the loss of continuity of the circular plaster.

After ample callus is in evidence, the wires and cast may be removed and a long or short laced leather cuff brace applied. In fractures of the upper third, it is necessary for these braces to extend above the knee.

ABSTRACT OF DISCUSSION

DR F J GAENSLEN, Milwaukee. This paper illustrates the great advantages that have come through the use of skeletal traction and particularly through the use of the Kirschner technique which is deservedly becoming popular. I believe that more extensive use of skeletal traction will help toward attaining better results and shortening hospitalization periods materially, two factors in which not only the patient himself is vitally concerned but also insurance companies. Pressure sores, always to be feared when a cast is applied after simple traction may be dismissed from the mind when skeletal traction is used and the fixation nails or wires are incorporated in the cast. I would call attention especially to the danger of overriding in oblique fractures. Carey has shown that if a dog's femur is cut transversely and in this transverse fracture a mechanism is interpolated for measuring pressure this device will register far greater pressure on electrical stimulation of the thigh muscles of the anesthetized animal than is recorded during simple weight bearing. The marked tendency to displacement or sliding by of one fragment on the other is thus readily understood even though no weight bearing is allowed. Skeletal traction in such a case is especially useful since the incorporation of the Kirschner wires—one above and one below the site of the

fracture, will facilitate further spreading or angulation, should this be indicated after roentgen examination. In the case of fractures extending through joints there is often difficulty in holding the smaller fragment in place even after open reduction. I have maintained fixation by knitting needle spikes. These are readily driven through the bone provided the cortical shell is fairly thin. If the cortex is thick, I tunnel a path for the knitting needle with a Kirschner hand drill, following a suggestion of Dr. Blount to facilitate the driving in of the pin. If two pins are then inserted, more or less at right angles, very secure apposition and fixation are attainable. I believe that this method is far superior to metal or bone screws or nails. The needles are cut short but project sufficiently so that they can be readily located after beginning union, when they may be grasped with a wire nipper, after a nick has been made in the skin, and withdrawn without difficulty. Dr. West is rendering valuable service in again stressing the advantage of skeletal traction, in the differentiation of his cases into various groups, and in emphasizing the point that not all are treated along the same line.

DR. W. B. CARRELL, Dallas, Texas. I am sure that all will agree with Dr. West that certain definite principles must be carried out in the treatment of fractures even though the details of application may be varied. Several years ago it was customary to operate in more fractures in the leg than in recent years. When more was learned about handling traction cases, especially with the aid of the Kirschner wire operations were found to be unnecessary. Likewise, as more thought has been given to gentle manipulation with the advantage of suitable position of the leg and good temporary traction as described by Watson Jones, this plan has been used for many cases which were formerly treated in traction. Whether a fractured leg is treated with open operation or traction or the fragments are manipulated into position due regard must be given the soft tissues, with particular reference to the circulation. In a fractured leg of four or five days' duration with shortening, rapid and heavy traction may do as much harm as vicious manipulation. In such a case the weight should be increased gradually, with stretching of soft tissue which would otherwise be torn. If traction is applied immediately after the injury sufficient weight should be applied at once to overcome the deformity and there should be no additional damage in the soft tissue. This emphasizes another principle in fracture treatment, namely, that all fractures should be regarded as emergencies, and immediate reduction accomplished before soft tissue infiltration occurs.

DR. DANIEL H. LEVINTHAL, Chicago. I want to add to the emphasis that has been placed on early reduction. In spite of the fact that this has been mentioned over and over again, fractures continue to be treated by delayed reduction. Dr. West has added to the work of Orr and Thomson, Kirschner, Boehler and Hockenbush. I want to emphasize the necessity for the accurate introduction of the wire. I was recently called into consultation in a case in which a wire was to be introduced just above the condyles of the femur. Instead, it was introduced into the pouch and was dragged down through the knee joint, with resulting infection. A note of warning should be sounded to men in general practice regarding indiscriminate use of the Kirschner wire, just as in the matter of open reductions and plates. The combination of gas bacillus and tetanus antitoxin should always be at hand. Dr. West mentioned a patient who died of a gas bacillus infection. I am sure that if the combination of these antitoxins is at hand and is given early there will be few cases of gas gangrene. The importance of the posterior sag should be emphasized. Posterior sag in fractures of both bones of the leg produces a disalignment with weight bearing posterior to the os calcis. It is the result of negligence on the part of the surgeon in the course of treatment. I should like to know when Dr. West removes the wire, also how frequently he sees delayed union or nonunion in these fractures. In my experience, fractures of the middle lower third of the leg more frequently go to delayed union or nonunion than any other cases except fractures of the neck of the femur. There is one disadvantage of the wire over the nail in fixed skeletal traction in that one has to use the bow with the wire and leave it outside the cast. For this reason I prefer the Steinmann nail, as used by Orr and Thomson

for fixation above and below after obtaining the reduction and incorporating the nails within the plaster, as Dr. West does the wires with their bows, to maintain the position.

DR. W. K. WEST, Oklahoma City. In answer to Dr. Levintal's question regarding the time the wire is removed, there is no time limit any more than there is a time limit as to when one can remove fixation from the tibia. I think that in the lower leg type usually two weeks is long enough. In the shaft of the tibia they are probably kept on sometimes as long as eight weeks and then after that, of course, something else is maintaining the position. Regarding the possibility of nonunion I haven't had nonunion in the cases I have treated but of course the union is always very slow. After eight or ten or twelve or fifteen weeks, when I decide that it should be united I take off the appliance. I would just keep it there until union is obtained. In this series, of course, I did not have nonunion. I don't remember ever having any. I make that as a rather broad statement because I know that in many cases there is nonunion in spite of anything one can do. Regarding the argument of some of the general surgeons to the effect that the simple methods of treatment should be returned to that the wires and bows and wrenches and drills are too complicated and too expensive I do not think that they are. I think they are a permanent armamentarium and will be used indefinitely. They are not especially expensive. After one uses them a time or two, the technique becomes simple. I think it is also felt that there will be some cases in which this armamentarium is necessary and that there is a way in which many open operations may be avoided.

INCIDENCE AND PREVENTION OF INCISIONAL HERNIAS

HENRY W. CAVE, MD
Attending Surgeon to the Roosevelt Hospital
NEW YORK

Incisional hernias continue to remain serious surgical problems. Countless procedures have been advocated for the cure of them, numerous suggestions have been offered to prevent them.

It seems reasonable to presume that though considerable time and concentration are utilized in the performance of the operation within the abdomen, often a too hurried and careless closure is effected by a weary operator or an inexperienced assistant.

INCIDENCE

The incidence seems variable according to the reports. In hospitals where many hernias are operated on incisional hernias are less frequent than other types of ruptures. B. L. Coley,¹ in 3,000 consecutive herniotomies performed at the hospital for the ruptured and crippled in New York, reported only a 1.5 per cent incidence of postoperative hernias. During a four year period (1923 to 1927, inclusive) at the Boston City Hospital² there were 304 patients with this condition operated on. Stanton³ noted 24 postoperative hernias following 500 laparotomies which he performed, all were ascribed to improper union of the fascial layers anterior and posterior to the rectus muscles. Masson⁴ cited a 10.8 per cent incidence of incisional hernias in 5,502 cases of hernia at the Mayo Clinic and found

that in a two year period (1928 to 1930) they had operated on 313 patients for this condition. A 5 to 10 per cent incidence is generally conceded in this particular type of herniation in comparison with all other forms of hernia.

In an attempt to determine accurately the incidence at the Roosevelt Hospital over an eleven year period (1922 to 1932, inclusive), it was found that 1928 hernias had been operated on, of these 120 were incisional hernias an incidence of 6.02 per cent. During this same length of time there were 5,366 abdominal operations, giving for postoperative hernia in this relationship an incidence of 2.2 per cent. An analysis revealed that the great majority of the hernias were in patients beyond the thirty-fifth year. A conspicuous feature in this series was that over 60 per cent of the hernias developed within two months following the original operation. This is somewhat at variance with the present conception, as most writers on the subject state that postoperative hernias are usually of delayed appearance and gradual development.

As most of the upper right rectus incisional hernias may be expected to follow operations on the gallbladder, I originally thought that retracting the muscle outward would lower the incidence, as this maneuver preserved the nerve supply and caused less destruction of muscle fibers. However, in the present series this was not found to be the case. The muscle-splitting procedure resulted in fewer postoperative hernias. The complication often feared in these wounds in the right upper quadrant is partial or complete disruption.

Twenty-eight postoperative hernias were encountered following lower right rectus incisions, in twenty of these twenty-eight cases appendectomies had been done with drainage, in four the appendix had been removed without drainage and in four pelvic procedures were carried out. These twenty-four cases in which the appendix was removed represent a rather large incidence when one considers the fact that this type of incision was employed only in doubtful cases.

With patients suffering from acute appendicitis it has been my custom when a definite diagnosis has been made to employ as a routine the McBurney incision in preference to the lower right rectus types of approach, for the following reasons: 1. Better drainage is effected. 2. There is less chance of spreading the infection for it is easier to wall off with moist tail pads through a McBurney incision than through a right rectus incision. 3. It diminishes postoperative herniation. I believe that by utilizing the Weir extension sufficient exposure is possible to remove an appendix no matter in what location it may be found or the right tube and ovary and occasionally, in a thin person, the left tube and ovary.

All of the thirty-six cases followed operations for acute appendicitis in which the peritoneum was drained.

Over a ten year period in one surgical division alone 444 patients were operated on for acute appendicitis through a McBurney incision and were followed up in 162 the wound was drained and in 282 not drained.

On each of these patients there has been a follow-up of from one month to two years when possible. The cases of drainage have been under observation for a two year period. In no instance has an incisional hernia

been detected in the nondrained group which shows the value of the McBurney incision. On the other hand, in 162 cases in which the wounds were drained twenty-one patients developed definite postoperative incisional hernia giving an approximate incidence of 12.9 per cent.

During the last nine years I have made it a practice in certain types of cases to leave the wounds entirely open except for closure of the peritoneum snugly about the drain in order to avoid extensive sloughing of the fascia of the external oblique muscle. In 1921 Pool, at the New York Hospital, began a series of operations in which this idea was fostered. Garlock⁶ in 1929, reviewing this group, reported that "the number of postoperative ventral hernia has been reduced more than half since the practice of avoiding the placing of sutures in muscles, fascia, or skin was adopted." In a series of 162 followed cases at the Roosevelt Hospital

Data on Postoperative Hernia

Anatomic Type	Pathologic Variety	Number of Operations*	Early Operative Deaths	Delayed Operative Deaths after 1st Day Post-operative	Total Number of Deaths	Deaths from Simple Hernias
Upper right rectus	Simple hernia	24	0	0		
	Strangulated hernia	1	1	0	1	0
Lower right rectus	Simple hernia	23	0	1		
	Strangulated hernia	5	0	2	3	1
McBurney	Simple hernia	55	0	0		
	Strangulated hernia	1	0	0	0	0
Lower midline	Simple hernia	16	0	0		
	Strangulated hernia	3	1	0	1	0
Miscellaneous	Simple hernia	11	0	0		
	Strangulated hernia	1	0	0	0	0
Totals		120	2	3	5	1
Mortality rate			1.6%	2.5%	4.1%	0.0%

* Where the procedure of the original operation could be determined it was found that the wound had been originally drained in 64 of the 120 cases and not drained in 56.

I was unable to confirm Garlock's conclusion, an investigation was stimulated by the observation that the great majority of the McBurney incisional hernias followed primary operations in which the wounds had been left open, except for suture of the peritoneum alone.

In the lower midline incision group nineteen cases followed operations on the prostate or the pelvic viscera, done elsewhere or by the general surgeons on the staff.

There were twelve hernias following operations of various kinds, such as cecostomies, recurrent umbilical hernias, nephrectomies and ureterectomies for tuberculosis.

PREVENTION

Etiologic factors should be considered in suggesting measures which I believe lower the incidence of these hernias. The belief is well founded that any wound necessitating drainage of the peritoneal cavity evokes a potential hernia. Views have been advanced that where catgut is used the rate of absorption or dissolution of the strands varies according to altered chemical reactions in different persons; thus in certain patients the catgut is too promptly deprived of its function, the

wound separates in the inner layers and an incipient hernia is inaugurated. Widespread is the conception that operative abdominal wounds in patients afflicted with cancer, diabetes and syphilis heal slowly and insecurely, yet if disruption occurs and the wound is carefully resutured how firmly they finally heal!

Infection unquestionably produces a more rapid disintegration of catgut, knots more easily slip apart when

Fig A—Drawing showing the various stages in the approach to the right upper quadrant of the abdomen. The left half of the rectus sheath and rectus muscle are pushed far over toward the midline as is shown in 1 and 4.

bathed by infected serum or frank pus, and a cough, sneeze, hiccup or increased abdominal pressure from whatever cause readily forces a small bit of omentum or even a knuckle of bowel wall up between the edematous, sloughing edges of the peritoneum. Unless interrupted sutures are used the peritoneal wound may be forced open throughout its entire length. In a mildly infected upper right rectus gallbladder incision I have seen on the seventh postoperative day every peritoneal (or anterior rectus sheath) interrupted suture of chromic catgut tear through the medial peritoneal edge under the sudden pressure of a severe cough, and yet not a suture has been found untied or in any manner disintegrating.

With sloughing of large areas of fascia of the external oblique or of the rectus sheath in infected wounds, it is easily understood why herniation so readily follows. To prevent sloughing it is deemed wise to suture only the peritoneum in an infected McBurney wound, and in the infected rectus or midline incisions interrupted sutures, properly spaced, permit of seepage, and the avoidance of excessive tension will mitigate against the embarrassment of the circulation of the tissue layers.

Competent abdominal surgeons less frequently drain the slightly, or even moderately, infected peritoneal cavity. Shipley and Bailey⁷ do not employ drainage in acute appendicitis with early peritonitis. They emphasize that "the important things in early peritonitis are not the kind and number of organisms in the peritoneum or the amount or extent of the exudate, but the source of the infection and whether or not the avenue through which the organisms are reaching the peritoneum may be gotten at and closed. If this can be accomplished in the early stages of peritonitis, drainage need not be so widely used as has been practiced." One of their conclusions states the matter clearly: "drains are soon sealed off and do not drain any considerable portion of the peritoneum." By closing cholecystectomy wounds without drainage many incisional hernias have been prevented. I believe, however, that this should not be done always as a routine. To close the wound tight and drain through a stab wound in the right flank serves the twofold purpose of firm closure and drainage, a dog tongue-shaped right lobe of the liver may make drainage by the flank stab wound too circuitous, thus necessitating the use of a drain in the upper angle of the right rectus wound. The wounds of the abdominal wall in practically all operations on

Fig B—Drawing showing the incision through the posterior sheath of the rectus muscle transversus fascia and peritoneum well over toward the midline in 1, 2, 3 and 4 show the method of stay suture of the peritoneum buried stay sutures for the rectus muscle sheath and interrupted figure of eight sutures for the anterior sheath of the rectus muscle.

the stomach are closed without drainage, thus accounting for the relatively few cases of herniation in the left upper quadrant.

Drains should be left in the peritoneal cavity for a minimum period of time. To minimize and sometimes

7 Shipley, A. M. and Bailey, H. A. Treatment of Appendicitis Complicated by Peritonitis. *Ann Surg* 96: 537 (Oct.) 1932.

prevent the occurrence of a postoperative hernia, employ the soft cigaret or Penrose drain in preference to glass tubes, rubber tubing or any variety of wrapped tube drain.

The smallest piece of omentum protruding through a pinpoint opening in the peritoneum, either in the line of suture or through a needle tear or slit to the side of either edge, produces a large percentage of postoperative hernias.

To prevent incisional hernias in wounds of the anterior abdominal wall, clean or infected, a meticulously careful suture of the peritoneum, transversalis fascia and posterior sheath of the rectus is of paramount importance. Secure apposition of the cut edges of the transversalis fascia is the keystone to a firmly united wound. A separate suture for this particular muscle fascia layer, if it is well developed, is an added safeguard.

A satisfactory closure of any wound is one wherein anatomic structures are perfectly replaced and held thus by some material which will not interfere with a safe and complete healing. In an actually or potentially infected wound catgut is unquestionably the suture and ligature material of choice, whereas in a clean wound I am convinced that silk has proved itself preferable, for two reasons, first, that a clean wound is less likely to become infected, and second, that fewer postoperative hernias result.

The following procedure in the closure of a clean upper, middle or lower right rectus wound, I feel certain will lower the incidence of, and no doubt at times prevent incisional hernia. In a measure the type of approach to the peritoneal cavity is of importance. A muscle-splitting procedure predisposes to a more firmly healed wound, and particularly does it conform to the closure herein outlined. I prefer the incision through the posterior sheath of rectus, transversalis fascia and peritoneum to be made more medially (from $\frac{3}{4}$ to 1 inch [2 to 2.5 cm]) than the incision through the skin, anterior sheath and rectus muscle. The reason is that this layer is thus more easily closed, for the outward pull of the horizontal fibers of the transversalis muscle is strong, and the closer one gets to the midline the less is the chance of pulling and tearing this most important structure. As a rule, the peritoneum, transversalis and posterior sheath of the rectus are closed with eversion of the edges by a running mattress suture which is locked at several points before it is finally tied at the lower angle of the wound. The greatest care is exercised in obtaining a firm bite in the transversalis fascia to close this structure well with a nonabsorbable suture almost certainly insures against incipient herniation. The next step is to undermine the skin and subcutaneous tissue for a distance of $1\frac{1}{2}$ inches (3.8 cm) on either side preparatory to the placing of deep or buried stay sutures of doubled medium-sized silk as suggested by Hensel: four or five such sutures are placed about 1 inch from the cut of the anterior sheath and rectus muscle and are left untied. Interrupted mattress or figure-of-eight sutures then firmly close the anterior rectus sheath. The buried stay sutures are pulled taut and carefully tied each suture including anterior rectus sheath and rectus muscle. Fine properly spaced interrupted sutures approximate the subcutaneous tissue and interrupted sutures close the skin.

I believe that of wounds in the lower part of the abdomen aside from the clean McBurney incisions one

made in the midline from the umbilicus to the symphysis offers more in the prevention of incisional hernia than one in which a small strip of rectus muscle is preserved, for surely this strip of muscle atrophies and leaves an area of weakness where herniation is likely to occur.

In the gynecologic service of the Roosevelt Hospital postoperative hernias occur rarely, owing primarily to few drained wounds and utilization of Pfannenstiel's incision, however, where midline incisions are used, great care is exercised in exposing the muscle at the time of closure and in suturing like structures by layers. In any noninfected wound in the lower third of the abdomen, where the muscles appear friable and the fascia itself is thin, an imbrication of the fascial layer by means of a running suture of living or dead (ox) fascia will guarantee a solidly healed wound.

In those unfortunate patients in whom a repaired incisional hernia recurs, sutures of either living fascia or the ox fascia of Koontz are often indicated, even at the primary operation. I have found that ox fascia soaked in warm saline solution for two hours prior to using it provokes scarcely more reaction of tissues than strips of living fascia lata, and I consider it necessary in suture equipment, in fact useful in the repair of any form of rupture. Insistence that every obese or debilitated person with an incisional hernia undergo a proper preoperative preparation will lessen the chance of recurrence.

SUMMARY

Incidence—Over an eleven year period at the Roosevelt Hospital (1922 to 1932, inclusive) there were 1928 hernias operated on. Of these, 120 were incisional hernias, an incidence of 6.02 per cent. An analysis of the 120 postoperative hernias showed that the great majority were in patients beyond the thirty-fifth year. Over 60 per cent of the hernias developed within two months following the original operation. In the right upper rectus incisions retraction of the muscle outward resulted in more incisional hernias than occurred in the muscle-splitting procedures. In the intermuscular incision group thirty-six incisional hernias followed operation for acute appendicitis in which the peritoneum was drained. In a follow-up group of 444 patients operated on for acute appendicitis through the McBurney incision the peritoneal cavity was drained in 162 and not drained in 282. Of the 162 patients in whom the wounds were drained twenty-one developed definite postoperative incisional hernias giving an approximate incidence of 12.9 per cent in this group. I do not agree with Garlock's contention that there are fewer postoperative hernias following suture alone of the peritoneum in the drained McBurney wounds.

Preventive Measures—1. Drainage of the peritoneal cavity is employed less frequently by competent abdominal surgeons. Cholecystectomy wounds are closed tightly. Where indicated one should employ stab wound drainage through the right flank. The drains are left in the wounds for a minimum period of time. Cigaret drains are preferable.

2. Suture of the peritoneum and transversalis fascia in the upper third of the abdomen is the most important step in the closure of any wound. In the lower third of the abdomen imbrication should be done with running sutures of live or dead (ox) fascia.

3. Where possible all wounds are sutured by layers. Excessive tension is avoided.

4 Fascial repair is done in every case of recurrent incisional hernia.

5 Patients suffering from systemic disease should undergo careful preoperative rehabilitation

6 The use of silk is preferred throughout in the closure of clean wounds

107 East Sixty-Seventh Street

ABSTRACT OF DISCUSSION

DR AMOS R KOONTZ, Baltimore I am especially interested in what Dr Cave had to say about the use of silk in the closure of clean wounds. Silk has two advantages. First, it is not absorbed and therefore can be depended on to stay where it is placed until firm healing is secured. Second, there is very little reaction in the tissues around the silk sutures. The one big disadvantage of silk is that in the presence of infection it acts as a foreign body, and a sinus forms and persists, going down to the offending suture until the suture works its way out or is removed by the surgeon. This single disadvantage of silk is far outweighed by its advantages. Infections in clean wounds are now so rare as to be almost entirely negligible. On the other hand, what are some of the experiences with catgut? The chemicals with which catgut is treated in preparation cause a moist reaction in the tissues and a type of healing not nearly so firm as that obtained after suture with silk. Every one who has used much catgut has seen abdominal wounds break open two or three weeks after operation and the patient temporarily disemboweled. I have never seen that happen with silk. Another important point is the preoperative preparation of obese persons before attempting a cure for a postoperative hernia. Excessively obese persons should be put on a rigid diet and have their weight materially reduced. A great deal of the excess fat of obese persons is carried in the omentum. This increases intra-abdominal pressure. Besides, the fat in the abdominal wall weakens that structure and both these factors militate against a cure of the hernia. Dr Cave makes it a practice to soak on fascia in physiologic solution of sodium chloride for two hours before operation. This is an excellent practice, as it is highly desirable to get all the alcohol removed before the fascia is implanted. One very important point in the operation for postoperative hernia, especially when fascia strips are used, is the question of drainage. Most of these patients are more or less obese, and a very extensive dissection is necessary in order to free the fascia in all directions from the large defect. If these wounds are not drained a certain amount of serum almost invariably collects and tends to soften the tissues and delay healing. If the wounds are drained through an opening in the operative incision, secondary infection almost invariably ensues. My practice has been to use cigaret drains through stab wounds in the flank. These drains may be removed in from three days to a week and they keep the operative site absolutely dry, thus promoting firm and secure healing.

DR ROBERT L PAYNE, Norfolk, Va. The ideal closure of an abdominal incision should include three factors: first, the approximation of every separate and distinct layer, second, total and complete obliteration of all dead spaces, third, the consummation of the first two points without tension on the blood and nerve supply of the tissues. I subscribe to the author's view that all ventral hernias begin from the inside out and that the most important structure of all those in the abdominal wall to coaptate properly is the transversalis fascia or the posterior sheath of the rectus. If this is properly approximated and held, the other structures will not separate. I believe that we are eventually going back to the procedures of our fathers and close all wounds with interrupted sutures. I believe that silkworm gut through and through with careful separate coaptation of all the layers and with whatever material the individual operator prefers will give the best result. I cannot subscribe to the author's views regarding the use of silk. The first three years of my professional life I spent pulling out silk suture knots that were used in the hospitals where I worked. I never put in silk except in overlapping the full thickness of the abdominal wall and then only after boiling that silk on three consecutive days. One of the best procedures for the protection

of the patient against the occurrence of an incisional hernia is careful supervision after operation and providing for thorough and consistent postoperative narcosis. I mean by that that morphine or some other form of narcosis should be used freely enough to prevent those mechanical factors that contribute so much to incisional hernia from cutting of the tissues by sutures in the first four or five days after operation.

DR GEORGE A HENDON, Louisville, Ky. I set about trying to find a simple way to close incisional hernias and to eliminate mortality. I chose a method by which I could perform the operation without opening the peritoneal cavity unless there was a specific reason to do so. When this was done the opening was immediately closed. I proceeded on the basis, which is an essential and vital factor in all plastic surgery, of obtaining contact without tension. I also realize the importance of the principle in plastic surgery that, other things being equal, the chances of success are in proportion to the area of fresh surfaces that are brought into contact. Therefore, the problem is to increase the area of contact and reduce the degree of tension. For that purpose the superficial abdominal fascia around the hernia protrusion is exposed for at least an inch from the margin of the ring. A suture is started as far back as possible and is carried through the fascia to emerge about one-fourth inch from the margin of the ring. The needle is then made to jump over the hernia opening and is again started into the fascia about one-fourth inch from the margin of the ring and emerges from the fascia as far back as the exposure will allow. A mattress suture may be used if one wishes to do so. When the sutures thus introduced are tied, there is a shelf of tissue turned inside the abdomen which divides the tension and increases the area of surfaces in contact. Pressure on the shelf will push it against the inner surface of the abdomen and tend to strengthen the closure. One thus avoids the morbidity, shock and danger incident to the opening of the peritoneal cavity. There is no danger of including the intestine in the suture line, because it is pushed away when the peritoneal and transversalis fascia is turned in. I often use this method of closure in the primary operation.

MEDICINAL TREATMENT OF THE COMMON COLD

HAROLD S DIEHL, MD

MINNEAPOLIS

Although the public takes more medication for colds both on prescription and without prescription, than for the treatment of any other illness, little of real significance has been written concerning the treatment of colds. The Thomsons,¹ in their exhaustive review of over 2,000 papers on the common cold, devote only about five out of 700 pages to the subject of general medicinal treatment and then conclude concerning the various drugs which they mention that "no doubt all of these are of some value. Nevertheless, they frequently fail to produce the desired effect so that one cannot be by any means certain of their efficiency." In view of such knowledge, it seems like distinct temerity to suggest that certain well known drugs are of definite value in the treatment of colds, but this is what it seems one must conclude, tentatively at least, from the results of a controlled study of the treatment of colds which has been in progress for approximately a year at the Students' Health Service of the University of Minnesota.

Read before the Minnesota Society of Internal Medicine Nov. 13, 1933.

Supported by a grant from the Medical Research Funds of the University of Minnesota.

From the Students' Health Service and the Department of Preventive Medicine and Public Health of the University of Minnesota.

¹ Thomson David and Thomson Robert. *The Common Cold*. Annals of the Pickett Thomson Research Laboratory. London: Baillière Tindall & Cox and Baltimore: Williams and Wilkins Company, 1932.

The reason for inaugurating this study was the consistently good results I obtained in the treatment of my own colds with morphine.² A one-fourth grain (16 mg) tablet by mouth at bedtime on two consecutive nights was the usual dosage taken, although on several occasions complete relief followed a single dose. It was in order to determine whether similar results would occur in other persons that the study was undertaken.

EXPERIMENTAL PROCEDURE

The agency through which this study is being conducted is the dispensary of the Health Service of the University of Minnesota, to which students come for medical advice and treatment. The following bulletin to the physicians of the Health Service Staff will explain the procedure followed in the study.

A STUDY OF THE TREATMENT OF COLDS

As explained at the staff meeting on Nov. 2, 1932, it is proposed to determine the therapeutic value or lack of value of a certain drug which gives some indication of being useful for the treatment of acute head colds.

The plan to be followed is this: select for this study students who have acute coryza, preferably of one or two days' duration. Tell these students about the study and explain that we will be glad to give them the medication which we are trying if they will report what effects, if any they observe. Unless students are willing to report results, do not include them in this group.

The nose and throat of each student who is to receive this medication should be examined and notes made on the student's dispensary record as to symptoms, date of onset of cold, and objective findings. A prescription giving the student's name, address, and weight should then be written for "Cold Medication." The pharmacist will fill this prescription according to directions. With the medication the student will receive a card upon which to report results, but in addition to this report he should be requested to return to the Health Service in two or three days for another inspection of the nose and throat. At this time the examining physician's impression as to whether or not there has been improvement objectively should be recorded.

The instructions to the pharmacist were to fill these "cold prescriptions" alternately with cold medication A and cold medication B. Cold medication A consisted of morphine sulphate in the following dosage: weight less than 100 pounds, (45.5 Kg) $\frac{1}{8}$ grain (8 mg) at bedtime, weight 100 to 149 pounds (45.5 to 67.6 Kg) $\frac{1}{4}$ grain (10 mg) at bedtime, weight 150 pounds (68 Kg) or more, $\frac{1}{2}$ grain (16 mg) at bedtime. Cold medication B consisted of lactose tablets of the same size, shape and color as the morphine tablets. The directions issued with the lactose tablets were the same as with the morphine. Two tablets were given on each prescription with the following directions: "Take one tablet, and only one, with water before retiring. If symptoms of cold are present the following evening, take the second tablet. Do not give either of these to any one else." No instructions were given in regard to diet, rest, hot baths, gargles and the like. The box containing the tablets was enclosed in an envelop in which was printed the instructions given in figure 1.

DETERMINATION OF RESULTS

The card for reporting results which was filled out by the person who received the medication is shown in figure 2.

² Morphine was first used by the author to treat a cold merely as a substitute for powder of opium and opium (Dover's powder) but reference to prior use of this drug in colds is given by the Thomson who quite flatly states as follows: "The treatment I first tried was a single dose of morphine or $\frac{1}{4}$ made up with a little capsaicin and of menthyl prep. (a small dose of eucalyptol is also advantageous) in two hours 10 grains of a grain and a hot bath. The following morning a large dose of morphine sulphate is given to clear away the uretic contents held back by the morphine."

When these report cards were returned they were checked for accuracy with the physician's notes on the dispensary record and classified as to type of cold and as to results of treatment. Classification as to type of cold was into one of the following groups: (1) acute coryza, i. e., colds of not more than four days' duration with serous discharge from the nose and with or without sore throat, headache, fever or other symptoms, (2) subacute or chronic head colds, i. e., colds with mucopurulent nasal discharge or with a serous discharge of more than four days' duration, (3) influenza

COLD MEDICATION

You will find enclosed some medication for the treatment of your cold. Our experience indicates that certain prescriptions which we are using are beneficial to most people but we want to check this carefully and request that you assist us in so doing by reporting results critically favorable or unfavorable on the card which will be sent to you in a few days thru the University mail.

After filling in the card return it to the Health Service thru the University mail.

If you should fail to get relief by the time that you have taken all of this medicine please return to the Health Service for a different prescription. If relief is obtained with this medicine but symptoms recur return for a refill of the same prescription.

Fig. 1—Instructions to patients

i. e., acute infections of the upper respiratory tract characterized by headache, fever and general aching but without nasal discharge, (4) pharyngitis, i. e., a sore throat, with or without fever, headache, and the like but without nasal discharge, (5) other acute respiratory infections.

Any classification such as this based on symptoms is of course, subject to inaccuracies, for an acute respiratory infection may be a pharyngitis today and a rhinitis, laryngitis, tracheitis or bronchitis tomorrow. Furthermore, coryza is a frequent complication of various respiratory infections such as influenza and pharyngitis. This tends to make the acute coryza group somewhat heterogeneous, but since, as the report will show, the inclusion of cases that were primarily influenza or pharyngitis tends to diminish rather than increase the proportion of good results, the classification will serve reasonably satisfactorily for these purposes.

Name
Date of beginning of cold
Symptoms before taking medicine—watery discharge from nose— (check) sore throat—thick yellow discharge from nose —headache—fever—general aching Other
Date of first taking medicine—
Condition next day (Note marked change)
Was medicine taken on this day?
Condition on following day
Impressions as to effectiveness of treatment, i. e., did this cold run its usual course, if not in what way was it different?

Fig. 2—Card for reporting results of medication

The cards reporting results were rated as indicating "definite improvement," questionable improvement or "no improvement." The ratings were made by me and independently by another physician without either of us knowing what medication had been given to the person making the report. Finally, the report from the pharmacist was obtained and the medication given to each patient was recorded.

These ratings, of course, represent merely the combined judgment of two physicians as to whether or not distinct improvement occurred immediately after treatment. No attempt was made to judge whether the

improvement, if any occurred, was the result of the medication, because the inclusion of a control group served to indicate how much improvement should be considered as due to spontaneous recovery. Some unselected examples of reports which were rated as showing "definite improvement," "questionable improvement" and "no improvement" are as follows:

DEFINITE IMPROVEMENT

- 1 First day "very little change" following day, 'much better'
- 2 First day, 'much improved', following day 'all symptoms relieved'
- 3 First day, improvement noticeable' following day, 'cold about gone'
- 4 First day, "better" following day 'cold much relieved and almost gone'
- 5 'Complete cure,' after first dose

QUESTIONABLE IMPROVEMENT

- 1 First day, cold was worse", second day, 'a little better. Comment: 'The cold seem to disappear in a day or two less than usual'
- 2 First day, "no marked change" second day, slight improvement"
- 3 First day, "no marked change, headache gone" second day, a little better voice clearer
- 4 First day, 'general aching eliminated perceptibly' other symptoms continued"

NO IMPROVEMENT

- 1 First day 'no improvement' second day, usual improvement"
- 2 First day, no noticeable change throat still sore second day, "about same as first day"
- 3 First day, no improvement second day no change cold ran usual course
- 4 First day no better', second day, about the same

As will be seen from these illustrations, there could be no question about the ratings that should be given to most reports. A few, however, are borderline and probably would be rated differently by different individuals. This might make some difference in absolute percentages of favorable and unfavorable results but, since the ratings were given without knowledge as to the medications received, it is probable that the differences between the results with the various medications would remain practically the same no matter by whom the ratings were given.

In figure 3 it will be seen that the proportion of reports rated as "questionable improvement" tends to increase as the proportion rated 'definite improvement' decreases. This probably is due to the fact that some improvement usually occurs from day to day in the regular course of acute colds and, since many students had heard favorable reports of the treatment, there was a tendency for them to report the usual progress of the cold as "slight improvement." For this reason only reports rated as "definite improvement" are considered of much significance.

MEDICATIONS STUDIED

Although this study was instigated for the purpose of determining whether morphine is of value in the treatment of acute colds, the scope of the investigation was extended as soon as it became evident that this question could be answered in the affirmative. Codeine, papaverine, dilaudid (dihydromorphine hydrochloride) and powdered opium were tried in the hope that they might prove more beneficial and less toxic than morphine.

The combination of codeine and papaverine was introduced with the thought that the codeine and the papaverine might be effective in different individuals. Dilaudid and papaverine were combined on the suggestion of Dr. Raymond Bieter, associate professor of

TABLE 1—Medications Studied and Dosages Used for Persons Weighing 150 Pounds

Medication	Dosage	Directions
Morphine sulphate	$\frac{1}{4}$ grain tablets	1 at bedtime
Lactose	Small tablets	1 at bedtime
Codeine sulphate	1 grain tablets	1 at bedtime
Papaverine hydrochloride	$\frac{1}{2}$ grain capsules	1 in a.m. 1 in p.m.
Codeine papaverine (1)	$\frac{1}{4}$ grain codeine with $\frac{1}{4}$ grain papaverine	3 at bedtime 1 in a.m. 1 in p.m.
Codeine papaverine (2)	$\frac{1}{2}$ grain codeine with $\frac{1}{2}$ grain papaverine	3 at bedtime 1 in a.m. 1 in p.m.
Dilaudid (1)	$\frac{1}{16}$ grain capsules	2 at bedtime 1 in a.m. 1 in p.m.
Dilaudid (2)	$\frac{1}{8}$ grain capsules	4 at bedtime 1 in a.m. 1 in p.m.
Dilaudid (3)	$\frac{1}{4}$ grain capsules	7 at bedtime 1 in a.m. 1 in p.m.
Dilaudid (4)	$\frac{1}{100}$ grain capsules	3 at bedtime 1 in a.m. 1 in p.m.
Dilaudid papaverine (1)	$\frac{1}{4}$ grain dilaudid with $\frac{1}{4}$ grain papaverine	1 in a.m. 1 in p.m. 3 at bedtime
Dilaudid papaverine (2)	$\frac{1}{2}$ grain dilaudid with $\frac{1}{2}$ grain papaverine	1 in a.m. 1 in p.m. 2 at bedtime
Acetylsalicylic acid acetophenetidin caffeine	$\frac{1}{2}$ grains acetylsalicylic acid $\frac{1}{2}$ grains acetophenetidin $\frac{1}{2}$ grain caffeine	1 in a.m. 1 in p.m. 3 at bedtime
Powder of Ipecac and opium (1)	$\frac{1}{2}$ grain capsules	1 in a.m. 1 in p.m. 1 at bedtime
Powder of Ipecac and opium (2)	$\frac{1}{4}$ grain capsules	1 after lunch 3 at bedtime
Opium powder	$\frac{1}{2}$ grain capsules	1 after lunch 3 at bedtime
Sodium bicarbonate	10 grain capsules	3 after each meal 4 at bedtime
Acetylsalicylic acid	$\frac{1}{2}$ grain capsules	1 every 2 hours first day and three times a day thereafter
Morphine papaverine	$\frac{1}{16}$ grain morphine with $\frac{1}{4}$ grain papaverine	1 in a.m. 1 in p.m. 2 at bedtime

pharmacology that papaverine might reduce the toxicity of the dilaudid. Later, papaverine was used in combination with morphine for the same reason.

Several other drugs extensively used in the treatment of colds viz., powder of ipecac and opium, acetylsalicylic acid, sodium bicarbonate, and acetylsalicylic acid-acetophenetidin and caffeine were added to the list of medications studied in order that their effectiveness might be evaluated in relation both to the control tablet and to the other drugs used. A complete list of the drugs studied and the dosages used for persons of average size is given in table 1.

TABLE 2—Reports Not Returned and Reports Discarded

	Number Not Returned	Percentages (of Totals Who Received Medication)	Number Discarded	Percentages Discarded
Morphine	27	8.1	26	9.1
Lactose	28	12.3	17	9.5
Dilaudid	2	1.1	8	7.8
Codeine	1	0.2	9	7.3
Powder of Ipecac and opium	1	1.2	5	6.4
Acetylsalicylic acid acetophenetidin caffeine	2	2.7	4	5.8
Opium powder	0	0.0	2	4.0
Dilaudid papaverine	1	1.0	4	4.2
Codeine papaverine	1	2.9	8	2.8
Sodium bicarbonate	2	3.3	1	1.7
Acetylsalicylic acid	6	10.0	1	1.5
Papaverine	1	7.1	1	0.0
Morphine papaverine	0	0.0	0	0.0
	96	1.9	88	3.8

Perhaps I should add that before any new drug combination was prescribed for students it was taken, in

larger dosage than was eventually used by me and frequently also by other members of the health service staff

REPORTS NOT RETURNED OR NOT RATED

Students who failed to report results within a week were sent follow-up notices with urgent requests for a report. As shown in table 2, a small percentage of students failed to respond even to these notices. Most

Constipation and diarrhea the frequency of which is indicated by the following percentages, were not considered as significant toxic symptoms. Constipation was reported after morphine by 26 per cent of the subjects, after codeine by 17 per cent, after opium powder by 46 per cent, after sodium bicarbonate by 42 per cent, after acetylsalicylic acid by 33 per cent, after dilaudid-papaverine by 21 per cent, after codeine-papaverine by 24 per cent, and after lactose by 12 per cent. Diarrhea was reported after morphine by 11 per cent, after opium powder by 23 per cent, after dilaudid-papaverine by 1 per cent, and after codeine by 17 per cent.

The frequency with which toxic effects were reported after the various drugs is shown in table 3. In considering this allowance must be made for the fact that some of these symptoms, such as those reported after lactose, were caused by the infection and not by the medications that had been taken.

RESULTS IN ACUTE CORYZA

As previously stated our so-called acute coryza group includes all persons who reported symptoms of a "watery discharge from the nose" and whose symptoms had not been present more than four days before treatment. Certainly most of the persons in this group had primary acute coryza, but in some cases the coryza was secondary to pharyngitis or influenza (grip). The results obtained with the different medications in this group of cases are shown in figure 3.

The percentages of individuals who reported definite improvement or complete cure of their colds within from twenty-four to forty-eight hours after taking morphine, dilaudid, codeine-papaverine, dilaudid-papaverine and morphine-papaverine are essentially the same, the differences in percentages of good results

TABLE 3—Toxic Symptoms Reported

	Total Reports Received	Percentage Reporting*						Percentage of Total or Report
		Nausea Vom. Itting	With out Vom. Itting	Faint or Faint Itting	Severe Head ache	Drowsy Feel ing	Diarr. or Const.	
Dilaudid dosages 1 2 3	99	4.0	9.1	0.0	1.0	7.1	1.0	11.1

* Only the one symptom which seemed most out of balance. In each case was tabulated.
† In ranking up the totals constipation and diarrhea were not considered as toxic symptoms.

being without significance.^{2a} Codeine-papaverine, dilaudid-papaverine and apparently morphine-papaverine, however, are preferable to morphine or dilaudid alone because of their being distinctly less toxic (table 3).

^{2a} Some of the improvement after each of the medications is of course temporary and is the result of the treatment.

Fig. 3—Various drugs in the treatment of acute coryza

of the failures, however, occurred early in the study or during examination or vacation periods.

Of the reports received, eighty-six were discarded without ratings because of one of the following shortcomings. The medication had not been taken in accordance with directions; the medication was discontinued because of toxicity; the statements on the report card were too ambiguous for classification; or the infection was in the lower rather than in the upper respiratory tract. Table 2 shows the numbers and percentages of reports discarded.

The relatively large proportion of reports discarded from persons who had received the morphine and lactose tablets is due to the fact that at the beginning of the experiment only one dose of the drug was given with instructions to return the following day to report results and to receive a second dose. However, because of the considerable proportion of patients who failed to return for the second dose, this plan was soon replaced in favor of the one that has been described. It will be noted also that the proportion of unsatisfactory reports is higher for the drugs which proved to be most toxic.

Although it would have been highly desirable to have all reports returned and rated, it is unlikely in view of the distribution of the missing and discarded reports that the results would have been much different had this been possible.

TOXIC EFFECTS OF THE DRUGS USED

A record was kept of all students who reported symptoms which they considered toxic effects of the drugs they had taken. The most common of these symptoms were nausea, vomiting, dizziness, drowsy feeling, and faintness or actual fainting. Fainting was reported to have occurred most frequently on rising in the morning after having taken the medicine the night before.

Codeine-Papaverine³—One hundred and sixty-one of the 216 individuals, 75 per cent, who took the codeine-papaverine combination for acute coryza, reported definite improvement or complete cure in from twenty-four to forty-eight hours. This is 14 per cent more than reported similar results from codeine alone, and 19 per cent more than from papaverine alone. With such differences, the odds are 45 to 1 that the codeine-papaverine combination is more beneficial than codeine alone, and 79 to 1 that the same combination is more beneficial than papaverine alone.⁴ Codeine and papaverine were tried together in several proportions and dosages, the chief of which are shown in table 1 as dosages 1 and 2. The difference in the percentages of good results with these two dosages, however, 74 and 76 per cent, respectively, is not sufficiently great to be of significance. Hence the smaller dosage $\frac{1}{4}$ grain of codeine with $\frac{1}{4}$ grain of papaverine, is now in use. The specific directions given with this codeine-papaverine combination to persons of various weights are as follows:

75 to 99 pounds 1 after breakfast, 2 at bedtime
100 to 129 pounds 1 after breakfast, 3 at bedtime
130 to 169 pounds 1 after breakfast, 1 after lunch 3 at bedtime
170 pounds and over 1 after each meal and depending on weight, 3 or 4 at bedtime

The change most frequently observed by persons who reported improvement was a prompt decrease or a complete disappearance of the nasal discharge and congestion. In many cases relief of the coryza was permanent following the first dose of the medicine, and even when there was a recurrence of congestion or discharge between doses the relief that followed the medication lasted for several hours. Furthermore, although the excessive secretion was controlled, the unpleasant dryness that usually occurs when atropine is taken for this purpose was not experienced. The pharyngitis, laryngitis and tracheitis that occur with certain colds were not materially affected by the medication. The relief of the coryza, however, very definitely reduced the discomfort and incapacity and in most cases seemed practically to eliminate the protracted period of mucopurulent discharge. This was particularly noticeable when the medication was taken at the very beginning of symptoms.

Unpleasant symptoms, such as nausea, dizziness, headache and fainting, were infrequent following the codeine-papaverine combination (table 3).

When one is prescribing derivatives of opium, a question as to the danger of habituation naturally arises. Concerning addiction to papaverine, New and Non-official Remedies⁵ says that "its toxicity is low, and neither tolerance nor habituation has been reported." Addiction to codeine may occur, but it is so rare that Wolff⁶ states that "codeine is not practically dangerous from the point of view of habituation and, like papav-

erine, does not come under the German opium law." Furthermore, the use of these drugs for the treatment of colds is occasional and for only short periods of time. Hence it would seem that one need have no concern in regard to habituation when using this drug combination for the treatment of acute colds.

Dilaudid-Papaverine—The results obtained with dilaudid-papaverine were practically identical with those reported for codeine-papaverine, the differences that appear in figure 1 being too small to be of significance. In at least two cases, however, dilaudid-papaverine gave prompt and permanent relief after the codeine-papaverine combination had produced only temporary improvement. Whether or not one of these combinations will tend to be effective in any considerable number of cases when the other is ineffective is being investigated. The proportion of patients who reported "definite improvement" after the dosages of dilaudid-papaverine (shown in table 1) were 77 and 80 per cent, respectively, a difference not sufficiently great to be significant. The specific directions given to the several weight groups for the use of the dilaudid-papaverine combination are the same as for the use of the codeine-papaverine combination.

The proportion of patients who reported toxic results after dilaudid-papaverine was approximately the same as after codeine-papaverine. The total incidence of toxic symptoms after dilaudid-papaverine, however, was only about one sixth as great as after dilaudid alone. These results, as well as those with the codeine-papaverine and morphine-papaverine combinations strongly suggest that papaverine may be effective in reducing the toxicity of morphine, codeine and dilaudid. The danger of habituation from the dilaudid-papaverine combination in the dosage used is certainly negligible if not absolutely nil.

Morphine-Papaverine—The number of cases treated with this combination is too small to justify generalizations, but since the results with it are no better than with codeine-papaverine or dilaudid-papaverine, there does not seem to be any reason for continuing its use. The toxic effects from the morphine-papaverine combination appear to be distinctly less than those from morphine alone.

Morphine—This drug, with which our study was started, is apparently of definite value in the treatment of acute coryza. However, the larger proportion of toxic results after it and the hesitancy of physicians to prescribe morphine because of the danger of addiction make it less desirable for extensive use than the several combinations already discussed.

Dilaudid (dihydromorphinone hydrochloride)—Beneficial results with dilaudid alone, in the larger dosages used, were approximately as frequent as with the other effective drugs or drug combinations, the proportions of "definite improvement" reported after dosages 1, 2, 3 and 4 (table 1) being 76, 69, 65 and 47 per cent, respectively. However, the large proportion of unpleasant effects after dilaudid (table 3) caused its discontinuance in favor of the less toxic combination of dilaudid with papaverine.

Concerning the dangers of habituation to dilaudid, Wolff⁶ says that "it has been shown both experimentally and clinically that it leads more slowly to habituation and addiction than morphine and its devotees are therefore more easily cured."

3 A patent application has been filed to enable the University of Minnesota to control the preparation and sale of the new drug combinations indicated by this study to be of value in the treatment of the common cold. Specifically these combinations are codeine with papaverine, dilaudid with papaverine and morphine with papaverine. It is not intended, however, that this patent shall interfere with the use of these drugs in the compounding of prescriptions written by physicians for their patients.

6 Wolff Paul Drug Addiction A World Wide Problem J. A. M. A. 98: 2175 (June) 1932.

Codeine—Codeine is evidently of definite though less value than morphine in the treatment of acute coryza. Toxic effects after codeine were just as frequent as after morphine.

Papaverine—Papaverine, which seems to be practically nontoxic, gives approximately the same proportion of good results as codeine (57 per cent of fifty-two cases and 61 per cent of eighty-three cases, respectively).

Powder of Ipecac and Opium—This powder, consisting of 10 per cent powdered opium and 10 per cent powdered ipecac, seems to have been first proposed for the treatment of colds by Dover, an English physician, in the seventeenth century. For many years it was extensively used, but pharmacists state that recently it has been almost completely replaced by the more actively promoted antipyretics, alkalis and the like. However, Cecil,⁸ in his book on colds, recommends powder of ipecac and opium as the medication of choice in the general treatment of colds.

The dosage in which powder of ipecac and opium was first used in this study was that ordinarily prescribed by physicians (dosage 1, table 1). Later the dosage was increased (dosage 2, table 1), so that the amount of available morphine which it contained was approximately the same as the amount of morphine that was being prescribed when morphine was given alone. With the larger dosage, however, there was no significant improvement in results, "definite improvement" being reported after dosages 1 and 2 by 54 and 58 per cent of cases, respectively.

The results (figure 3) with this time-honored remedy indicate that it has real merit. However, since powdered opium alone gives as good results as the powder of ipecac and opium, it would seem that its value lies in the ability of the opium to relieve the nasal congestion and secretion and not, as commonly supposed, in the stimulation of secretions and sweating produced by the combination of the opium and ipecac.

A few individuals reported nausea and vomiting following the powder of ipecac and opium but the percentage of these was small.

Opium Powder—Powdered opium was tried in order to compare the results with it to those obtained with morphine and with powder of ipecac and opium. The dosage of opium used was such that it contained approximately the same amount of available morphine as that administered when morphine was used alone. This also was the same amount of opium as was contained in the larger dosage of powder of ipecac and opium.

The percentage of persons reporting "definite improvement" with the powdered opium was less than with morphine, but the same as with powder of ipecac and opium (fig. 3). Why opium should be less beneficial than morphine or morphine-papaverine or codeine-papaverine is not clear, although it is possible that smaller proportions of these alkaloids are absorbed when opium is used than when the alkaloids are taken separately.

The proportion of toxic symptoms from the opium was the same as from morphine or codeine but greater than from the codeine-papaverine combination. The possibilities of addiction to opium are too well understood to need comment but certainly there is no danger

of developing habituation when the drug is used as it was in this study.

Lactose—It seemed essential at the beginning of this study to have reports from a series of patients who thought they were taking some presumably effective medication but who in reality received no medication whatever. For this purpose tablets and capsules of lactose were employed. The proportion of good results (35 per cent) reported after lactose is indicative of the spontaneous improvement in acute colds for which any medication that happens to be taken is given credit. It is because this percentage is so large that it is possible to convince the public that practically any preparation is of value for the prevention or treatment of colds. In fact, some of the comments that were made on the report cards by persons who had received only lactose tablets would serve admirably as testimonials concerning the value of these tablets for the treatment of colds.

It would have been desirable, of course, to continue this control group throughout the year, but after reports

UNIVERSITY OF MINNESOTA—STUDENTS HEALTH SERVICE	
Name _____	
Will you be good enough to answer a few more questions in order to help us to determine the value of the medication which you received for a cold on _____? These questions are	
1 How many days or half days were you absent from classes or work because of this cold?	
(a) before treatment _____ days	(b) after treatment _____ days
2 Did you stay in any other time over a week end or holiday because of this cold?	
(a) before treatment _____ days	(b) after treatment _____ days
3 What was the approximate total duration of this cold?	
_____ days	
4 Did you observe any unpleasant effects which seemed to be due to the medication such as diarrhea constipation etc? If so what? _____	
After filling in the answers to the above questions please drop this card in the University mail.	
If you received treatments for colds other than the one noted above additional cards will be sent you.	
H. S. DIEHL, M.D. Director	

Fig. 4—Follow up report on results of treatment

from a hundred patients had been received we did not feel justified in continuing it further.

Acetylsalicylic Acid-Acetphenetidum-Caffeine—The proportion of persons (37 per cent) who reported beneficial results from this drug combination is not significantly greater than that reporting benefit from the sugar capsule. A few stated that headache was relieved but that other symptoms continued unchanged. The majority, however, seemed to get no benefit whatever.

Acetylsalicylic Acid—Because acetylsalicylic acid is so widely used in the treatment of colds, it was tried alone. The proportion of good results (42 per cent), however, was not significantly greater than that with the sugar capsule.

Sodium Bicarbonate—During the past few years the so-called alkalinization treatment of colds, by means of sodium bicarbonate, other mild alkalis or citrus fruits, has been much advocated. Some of this has been based on medical writings,⁹ but most of it on the promotion of medicinal preparations or citrus fruits by advertisers.

In our study sodium bicarbonate in dosages of 130 grains (8.5 Gm.) a day for the adult of average size was used (table 1). This amount was believed suffi-

⁹ Cecil, R. L. Cold. Caring Treatment and Prevention. New York: D. Appleton & Co., 1922.

cient to produce at least as much "alkalization" as is usually obtained with this treatment. The results, as shown in figure 3, are approximately the same as those reported after acetylsalicylic acid, the acetylsalicylic acid-acetphenetidin-caffeine combination, and lactose. In other words, this study gives no evidence that alkalinization is of value in the treatment of the common cold.

TABLE 4—Duration of and Time Lost on Account of Acute Colds

Medication	Number of Cases	Average Time Lost After Treatment, Days		Percentages Who Lost No Time		Average Duration of Symptoms, Days	
		From School or Work	Usual Activities Total	From School or Work	Usual Activities Total	Before Treatment	After Treatment
Codeine papaverine	129	0.2	0.5	87.1	78.0	2.8	4.3

Dilaudid (dosages 1 and 2 and 3)	42	0.8	1.1	64.3	41.2	2.9	4.4

* Based on less than twenty-five cases; hence unreliable.

VARIATION IN RESULTS THROUGHOUT THE YEAR

Since no single medication was used continuously, it is impossible to speak with certainty of variation in results throughout the year. However, the results suggest that colds tend to become more severe as the winter progresses. This may be due to an increase in the virulence of the infections or, what is more likely, to a decrease in resistance of the victims.

TABLE 5—Results in Subacute and Chronic Colds

Medication	Total Cases	Percentages Reporting		
		Definite Improvement	Questionable Improvement	No Improvement
Codeine papaverine	47	36	21	39
Dilaudid papaverine	13	31	21	48
Morphine papaverine	8	25	13	62
Morphine	50	48	24	28
Dilaudid	15	47	26	27
Codeine	21	43	33	24
Papaverine	13	38	11	51
Opium powder	10	50	10	40
Powder of Ipecac and opium	5	20	12	68
Sodium bicarbonate	8	63	12	25
Acetylsalicylic acid acetphenetidin caffeine	10	30	30	40
Acetylsalicylic acid	11	36	27	38
Lactose	48	35	31	34

* Most of the percentages in this table are subject to considerable variability because of the small number of cases on which they are based.

A marked decrease in the proportion of reports of "definite improvement" in May with all medications was coincident with, if not actually due to, the prevalence among the student body of a severe infection of the upper respiratory tract characterized primarily by an acute pharyngitis. Many of these patients developed coryza and so were classified in the acute coryza group.

In December there was an epidemic of mild influenza, or grip, among the students. Some of these patients

developed coryza and so were given the "cold medications" in use at that time. One of these was the control tablet, and since most of these infections were very mild and of short duration, the proportion of persons reporting definite improvement following the lactose tended to increase during this period.

INFLUENCE OF TREATMENT ON TIME LOST AND ON TOTAL DURATION OF ACUTE COLDS

After this experiment had been in progress about a month, it was decided to check the results by comparing the amount of time lost and the total duration of colds following the various medications. Information relative to this was obtained from a card (fig. 4) which was sent to university students three weeks after treatment.

As may be seen by comparing totals in figure 3 and table 4, these reports of time lost were not received from nearly all the persons treated. For this there are several obvious reasons: viz., the loss of interest on the part of students because of the long interval of time between treatment and the request for this report, the occurrence of vacation periods at the time this report was due, a lack of follow up if the first card was not returned, and the sending of these cards only to certain students in order that all reports would be from individuals under similar regulations in regard to absence from class.

TABLE 6—Results in Influenza

Medication (4)	Total Cases	Percentage Reporting		
		Definite Improvement	Questionable Improvement	No Improvement
Acetphenetidin	33	48	20	22
Morphine acetphenetidin	37	42	29	29

The considerable proportion of these reports which are lacking introduces such a large element of possible error that the validity of results indicated by the tabulation is questionable. On the other hand, there is no reason to think that the comparative results with the different medications are not of some significance.

In table 4 are presented the average amounts of time lost from usual activities by patients who received the various medications. The proportion of each group who lost no time, and the average duration of symptoms before and after treatment. From this tabulation it appears that the loss of time by persons who received the medications indicated by figure 3 to be most beneficial and least toxic is significantly less than by those who received the least effective group of drugs.¹⁰ For example, the average amount of time lost from school or work by students who took codeine-papaverine (0.23 day) or dilaudid-papaverine (0.25 day), was approximately half as great as the amount of time lost by those who took sodium bicarbonate, lactose or the acetylsalicylic acid-acetphenetidin-caffeine combination, 0.52, 0.61 and 0.65 day, respectively. The total amount of time after treatment lost from all usual activities is in approximately the same ratio: viz., one-half day after codeine-papaverine or dilaudid-papaverine as compared to from one to one and a half days after sodium bicarbonate, lactose and the acetylsalicylic acid-acetphenetidin-caffeine combination.

10 The only exception to this is acetylsalicylic acid. The loss of time after which is only about half as great as after lactose or the acetylsalicylic acid acetphenetidin caffeine combination, which according to other reports are of as much value as acetylsalicylic acid. Hence this difference is doubtless without significance and due to the small number of cases.

The figures in regard to the total duration of the colds are of less significance because it is difficult to determine the exact date of termination of a cold. In general, however, these average durations tend to show differences between the medications similar to those suggested by the amounts of time lost.

RESULTS IN SUBACUTE OR CHRONIC COLDS

The group of subacute or chronic colds consists for the most part of individuals with colds of more than four days' duration at the time of treatment, although cases of shorter duration were included if a "thick yellow nasal discharge" was reported. The results of treatment in these subacute or chronic colds (table 5) give no indication that any of the medications used are beneficial. The actual percentages rated "improvement" show considerable variability, but in view of the small numbers of cases on which these are based the differences are without significance.

RESULTS IN INFLUENZA

The effect of morphine in mild influenza without coryza was tested both in ambulatory and in bed patients. The ambulatory patients alternately received acetphenetidin and acetphenetidin plus morphine in the dosages shown in table 1. All the bed patients received the acetylsalicylic acid-acetphenetidin-caffeine combination, but in addition every second patient was also given morphine in the dosage previously indicated.

As to the proportion of influenza patients in whom coryza developed and who consequently were included in our acute coryza group we have no information, but Doull and Bahlke¹¹ report that in an influenza epidemic among the resident nurses of Johns Hopkins Hospital, in the winter of 1928-1929 51 per cent of the patients exhibited coryza as a "first day" symptom. In connection with the study here reported, several members of the health service staff who had influenza with symptoms of coryza and who took morphine reported relief from the symptoms of coryza but no other effect on the course of the infection.

The summary of the reports from the ambulatory patients appears in table 6. Results in the hospitalized patients were estimated by comparing the average number of days that the two groups were confined to bed. These were 2.6 days for twenty-four patients who had received the usual treatment and 2.4 days for sixteen patients who in addition had received the morphine. None of these results suggest any value for morphine in the treatment of influenza without coryza.

RESULTS IN PHARYNGITIS

The cases of pharyngitis are too few to justify conclusions but the results do not suggest any value for the codeine-papaverine combination in this condition.

COMMENT

It seems quite definite from the results of this study that opium and the major alkaloids derived from it are of distinct value in the treatment of acute coryza. The chief result observed is a marked decrease or complete disappearance of the nasal congestion and discharge. This effect occurs promptly and is usually prolonged or permanent. Rest or sweating is not a factor although it is reasonable to suppose that secondary infections are less likely to develop if general hygienic measures are followed.

The failure to get good results with any of the medications in cases of influenza and pharyngitis suggests that the variability in results throughout the year may be due, in part at least, to differences in the types of infections causing the coryza. The absence of good results in subacute and chronic colds seems to indicate that beneficial results can be expected only before secondary infections have set in.

SUMMARY OF RESULTS

1 This study shows the relative values of various drugs and drug combinations in the treatment of 1,039 cases of acute coryza, 262 cases of subacute or chronic colds, 114 cases of influenza and 53 cases of acute pharyngitis.

2 Of the drugs studied, only opium and certain alkaloids derived from it seem to be of value in the treatment of acute coryza.

3 Combinations of papaverine with codeine, papaverine with dilaudid, and papaverine with morphine were followed by "definite improvement" in from 74 to 78 per cent of the cases and in the dosages used these combinations seem to be practically nontoxic.¹²

4 For general use a combination of codeine and papaverine seems most desirable because of the high percentage of good results obtained with it, its low toxicity, and the absence of danger, or at least of "practical danger" of habituation to it.

5 Morphine and dilaudid (dihydromorphinone hydrochloride) alone were followed by "definite improvement" in nearly as large a proportion of cases (73 and 72 per cent, respectively) but each was distinctly more toxic alone than when combined with papaverine.

6 Codeine, papaverine, powdered opium and powder of ipecac and opium were followed by "definite improvement" in from 56 to 61 per cent of cases. The toxicity of these drugs is in the following order: codeine, powdered opium, powder of ipecac and opium and papaverine, with codeine practically as toxic as morphine.

7 Powder of ipecac and opium although of value in the treatment of acute colds, is no more beneficial than the same amount of powdered opium without the ipecac.

8 Sodium bicarbonate, acetylsalicylic acid and a combination of acetylsalicylic acid-acetphenetidin-caffeine give little if any better results in the treatment of acute coryza than the lactose tablet used as a control, each being followed by "definite improvement" in from 35 to 42 per cent of cases.

9 A computation based on incomplete reports of time lost from their usual activities by patients who received the various medications suggests that it may be possible with the codeine-papaverine or dilaudid-papaverine combinations to reduce very materially the amount of time lost as a result of acute colds.

10 None of the medications studied seem to be of benefit in subacute or chronic colds.

11 Morphine was tried in influenza but was of no value.

12 The number of cases of pharyngitis treated were too few to justify conclusions but none of the drugs seemed of value.

Students Hospital and Dispensary

11. Doull, J. A., and P. H. Bahlke. Anna M., Ep. for Influenza, A C. = (part) of Clinical O. with in a Major A. I. M. J. Epidemic Am. J. H. 8: 17-21 (May 1931).

12. Further experience since the preparation of this paper with the dilaudid-papaverine combination shows it to be more toxic and of no greater benefit than the codeine-papaverine combination.

Clinical Notes, Suggestions and New Instruments

VINCENT'S INFECTION WITH REPORT OF A CASE WILLIAM THOMAS WILKINS JR M D PIQUA OHIO

For several months before the onset of a severe illness, a white man, aged 36, had recurring single canker sores on the tongue which would last a day or two and disappear without treatment. He was a man of cleanly oral habits, and dentists had repeatedly assured him that there were no pockets or ulcerated areas on his gums. A small canker was present in the mouth when the lower lip became chapped and cracked while the patient was on a fishing excursion. The ulcer of the tongue disappeared but the crack became deeper and quite tender. After a few days this soreness subsided.

About two days later, however, the lip again became sore and the region of the submaxillary glands was tender on chewing and on pressure. For the next five days the lip became increasingly tender, the crack became deeper and the adjacent mucous membrane took on a whitish cast. It felt thick to the tongue. The lips felt dry and parched. The interior of the mouth and the tongue felt hot and there was a suggestion of a metallic taste, but nothing abnormal could be seen in the mouth except that the upper surface of the tongue was possibly slightly more pink than usual. The submaxillary glands on both sides were now easily palpable and quite tender.

Fever in mild degree during the preceding few days was suddenly precipitated by a chill and the patient went to bed. Physical examination at this time revealed nothing more than has been described. The gums seemed entirely normal. The tonsils were out. The pharynx and nares were normal. The temperature was 102 F, pulse 95, respiration 20. The chest, heart, abdomen, skin and extremities were normal. There was no lymphadenopathy beyond that in the neck. The patient was more toxic than his vital signs would indicate.

During the four days that followed the patient's going to bed the temperature varied between 100 and 102. Several other chills occurred. Tachemia increased. A gnawing burning sensation in the epigastrium was accompanied by anorexia and all foods taken into the stomach produced severe cramps. The epigastric region was tender to pressure and distended with gas. On swallowing, a sharp pain occurred deep in the chest in the sternal area. Here also a sensation of soreness and of great distress was constantly present. Two new canker sores appeared on the edge of the tongue. Smears taken from these and the lip and gums showed only an occasional spirillum as might be expected in a normal mouth. Blood cultures, blood agglutinations for tularemia, undulant fever and typhoid and urinalyses were negative. The blood count was 7500 white cells with 65 per cent polymorphonuclears. The day the patient went to bed. Two days later it was 8,500, and a week later 10,200.

For want of better treatment, 0.5 Gm of neoarsphenamine was administered. Twenty-four hours later, as if by explosion the gum surface of the entire mouth became swollen, red, boggy and very sore. Bleeding ensued. Smears were filled with Vincent's organisms, both spirilla and fusiform bacilli. The stomach pain, chest soreness and tongue ulcers were suddenly worse. Next day (forty-eight hours after the arsenical medication), all these symptoms were noticeably improved.

During the following two weeks a low grade fever continued. The swelling and ulcerations of the tongue and gums disappeared. Chest pain and gastric distress disappeared in three or four days after the first dose of neoarsphenamine.

The patient received three doses of neoarsphenamine intravenously and four doses of a bismuth compound intramuscularly, equivalent to 0.4 Gm of neoarsphenamine and 25 mg of metallic bismuth per dose during this period of two weeks. Mouth washes of strong sodium perborate solution and diluted hydrogen dioxide were given. The gums were painted two or three times daily with arsphenamine or bismuth solutions. Mouth washes had been carried out for some time before the patient went to bed and continuously afterward, but as far as could be noted from the course of the illness no benefit was derived from them.

Following each intravenous injection of neoarsphenamine the patient became nauseated and dizzy and had various hyperesthesias and visual disturbances. These symptoms seemed to be due to an idiosyncrasy to arsenic, for they appeared and disappeared regularly with the administration of the drug. Exacerbation of the symptoms and signs of the disease itself occurred only after the initial dose.

To summarize the course of the disease after the first injection of neoarsphenamine, the buccal, esophageal and stomach symptoms disappeared in four days, the lip was well in ten days, the glands lost their soreness in six days and were not palpable in ten days, the gums looked normal in two weeks. The patient lost 14 pounds (6.4 Kg) during his confinement of three weeks. Smears taken from the mouth eight days after the first dose of neoarsphenamine showed only an occasional spirillum and were negative in three weeks.

Orr-Flesh Building

Council on Pharmacy and Chemistry

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

PAUL NICHOLAS LEECH Secretary

ANTIPNEUMOCOCCUS SERUM (See New and Non official Remedies 1933, p 369 and THE JOURNAL, Dec 16 1933, p 1968)

E R Squibb & Sons, New York.

Concentrated Anti Pneumococcal Serum Types I and II—Prepared by immunizing horses with intravenous injections of cultures of type I and type II pneumococci. When test bleedings show the serum to have reached a sufficient degree of potency for types I and II pneumococci the horses are bled aseptically and the serum is refined and concentrated by the method described by Lloyd D Felton (*J Infect Dis* December 1928 p 543). The usual sterility and safety tests are made by injection into white mice and guinea pigs. The potency of the product is expressed in terms of the unit described by Felton (*Boston M & S J* May 15 1924 p 819 *J Infect Dis* September 1925 p 199 October 1925 p 309) and used by Park. While the unit originally was intended to be the amount of antibody that will protect against one million fatal doses of culture it has lately been taken to be 1/200 cc of the control serum (F 146) distributed by Dr Felton. Marketed in packages of one syringe containing 10 000 units each of types I and II.

Dosage—Intravenously first dose 10 000 units of each type followed by a second dose of 20 000 units of each type in one hour. The second dose may be repeated at intervals of from four to six hours until the temperature falls and beneficial effects are evident.

REPORTS OF THE COUNCIL

THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT

PAUL NICHOLAS LEECH Secretary

AMPULES SODIUM CACODYLATE 7½ GRAINS (0.5 GM), 5 CC (FOR INTRAVENOUS USE)

AND AMPULES SODIUM CACODYLATE 15½ GRAINS (1.0 GM), 10 CC FOR INTRAVENOUS USE (CHEPLIN BIOLOGICAL LABORATORIES)

NOT ACCEPTABLE FOR

N N R

The Cheplin Biological Laboratories presented these ampules of sodium cacodylate (among others) for consideration as to inclusion in New and Nonofficial Remedies. In a submitted circular, these particular ampules are stated to be for intravenous use. The Council holds that the desired effects of sodium cacodylate may be achieved by oral administration of the drug or in exceptional cases that the intramuscular route may be desirable. The Council recently omitted from New and Nonofficial Remedies ampules of sodium cacodylate labeled "for intravenous administration" even though the manufacturer made no propaganda for such use in the advertising for the product (THE JOURNAL, May 7 1932, p 1654). The Council was therefore obliged to hold Ampules Sodium Cacodylate 7½ grains (0.5 Gm) 5 cc, and Ampules Sodium Cacodylate 15½ grains (1.0 Gm) 10 cc (Cheplin Biological Laboratories), both designed for intravenous use unacceptable for inclusion in New and Nonofficial Remedies.

Committee on Foods

ACCEPTED FOODS

THE FOLLOWING PRODUCTS HAVE BEEN ACCEPTED BY THE COMMITTEE ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION FOLLOWING ANY NECESSARY CORRECTIONS OF THE LABELS AND ADVERTISING TO CONFORM TO THE RULES AND REGULATIONS. THESE PRODUCTS ARE APPROVED FOR ADVERTISING IN THE PUBLICATIONS OF THE AMERICAN MEDICAL ASSOCIATION AND FOR GENERAL PROMULGATION TO THE PUBLIC. THEY WILL BE INCLUDED IN THE BOOK OF ACCEPTED FOODS TO BE PUBLISHED BY THE AMERICAN MEDICAL ASSOCIATION.

RAYMOND HERTWIG Secretary

CEMAC

A FOOD FREE FROM CEREAL, EGG AND MILK
FOR ALLERGIC CHILDREN

Manufacturer—Mead Johnson and Company, Evansville, Ind

Description—Cooked mixture of cauliflower tomatoes, beef carrots, spinach, olive oil sucrose 'Dextri-Maltose' (essentially a mixture of maltose and dextrans), gelatin, dicalcium acid phosphate, cod liver oil and sodium acid phosphate prepared by efficient method for retention in high degree of the natural mineral and vitamin values

Manufacture—Government inspected beef is ground and mixed with cleaned and chopped cauliflower, tomatoes, carrots and spinach, in a double jacketed, closed type steam kettle water is added the kettle is closed the air is pumped out, and steam is introduced into the outside jacket. The method of cooking minimizes vitamin loss through oxidation. The mixture is strained, admixed with the other ingredients, homogenized filled into tins, hermetically sealed, and processed under 15 pounds steam pressure for forty-five minutes

Analysis (submitted by manufacturer) —

	per cent
Moisture	74.8

Iron (Fe)	0.008
Copper (Cu)	0.0015

Calories—1.3 per gram 37 per ounce

Claims of Manufacturer—A food free from cereal, egg and milk for children allergic to the proteins of these foods. Designed to supply all the nutritive requirements for normal growth

FAIRWAY WHITE LABEL BRAND MIXED VEGETABLES

Distributor—Twin City Wholesale Grocer Company St Paul and Minneapolis

Packer—The Larsen Company Green Bay, Wis

Description—Mixture of carrots, potatoes, celery, green beans cabbage peas corn lima beans onions sweet peppers salt and water prepared by efficient methods for retention in high degree of the natural mineral and vitamin values the same as the accepted Larsen's Veg Mix (THE JOURNAL Aug 12 1933 p 525)

PLIFFING UNSWEETENED STERILIZED EVAPORATED MILK

Distributor—Plee Zing Inc Chicago

Packer—Pace Milk Company Merrill Wis

Description—Canned unsweetened evaporated milk the same as Pace Evaporated Milk Sterilized Unsweetened (THE JOURNAL May 20 1931 p 1872)

CASEC (CALCIUM CASEINATE)

Manufacturer—Mead Johnson and Company, Evansville Ind

Description—Powdered calcium caseinate, readily miscible with water, forming a turbid suspension

Manufacture—Skim milk is acidified with acetic acid to precipitate the curd, the whey is removed by decantation. The curd is washed free of whey salts, lactose, lactalbumin and acid, and is heated with a slight excess of precipitated calcium carbonate until the curd dissolves with the formation of calcium caseinate. The excess of calcium carbonate is removed by centrifugation. The calcium caseinate is dried in vacuum, powdered and packed in hermetically sealed tins in an atmosphere of nitrogen

Analysis (submitted by manufacturer) —

	per cent
Moisture	5.5
Ash	4.5

Calories—3.7 per gram 105 per ounce.

Vitamins—Contains a small amount of vitamin A

Claims of Manufacturer—To be used in accordance with the physician's instructions when a food especially rich in protein of high biologic value is desired

SWEET LIFE BRAND UNSWEETENED EVAPORATED MILK

Distributor—Grosberg-Cramer Company, Schenectady, N Y

Packer—The Page Milk Company Merrill Wis

Description—Canned, unsweetened evaporated milk, the same as Page Evaporated Milk (THE JOURNAL May 30, 1931, p 1872)

COLLEGE INN PURE TOMATO JUICE

Distributor—College Inn Food Products Company, Chicago

Packers—College Inn Food Products Company Chicago, and Welch Grape Juice Company, North East, Pa

Description—Tomato juice seasoned with salt retaining in high degree the vitamin content of tomatoes

Manufacture—Fresh, vine ripened tomatoes are washed in a squirrel cage type washer, under high pressure water spray which disintegrates any soft or badly damaged fruit. The sound, whole fruit is trimmed cored, inspected and passed through a steam box into a chopper, where it is cut into large segments and flowed into an American Utensil screw-type extractor. The head of fruit present at the opening of the juicer prevents the incorporation of air. The juice falls into aluminum kettles containing slow agitators is heated deaerated in a vacuum chamber, homogenized, pumped into the bottom of steam jacketed kettles to avoid aeration seasoned with salt again heated and automatically filled into containers (steam replaces the air in the top), which are capped and processed at 90 C for twenty minutes for bottled juice and at 100 C for forty five minutes for the canned. The time elapsing between the receiving of the tomatoes and the sealing of the filled containers is twenty minutes

Analysis (submitted by manufacturer) —

	per cent
Moisture	92.4
Total solids	7.6
Ash	1.0
Sodium chloride	0.6
Fat (ether extract)	0.0
Protein (N X 6.25)	0.0
Reducing sugars as invert sugar	4.1
Crude fiber	0.2
Carbohydrates other than crude fiber (by difference)	0.4
Titratable acidity as citric acid	0.4

Calories—0.3 per gram 8 per ounce

Vitamins—The methods of preparation processing and packing are efficient for protecting the natural vitamin content

Claims of Manufacturer—This tomato juice is a good source of vitamins A and B and an excellent source of vitamin C. Especially prepared for table use and as a vitamin C supplementary food for infant feeding

THE PHYSIOLOGY OF WATER

Only in comparatively recent years has the role of water in the body begun to receive the serious attention it has long deserved. True, some recognition has been given to the need of a water intake sufficiently large to compensate for the losses in respiration and perspiration as well as the more obvious output through the kidneys. However, the mere statement that water is the most abundant constituent of the tissues and is taken up and released in turn more rapidly than any other substance may suffice to indicate something of its ubiquitous biologic importance. In referring to the surprising fact that the average water content of the entire body is about 70 per cent, a recent textbook¹ explains the purpose of this aqueous component as obviously to provide a medium in which chemical actions can occur and physical chemical phenomena such as osmosis and diffusion can effect the necessary transfers of chemical compounds through tissue membranes. The actual dilution is presumably the optimal dilution for such changes. The author adds that any severe deprivation of water, leading to greater concentration of the chemical compounds present in the tissues, is followed at first by a sensation of thirst and subsequently by a series of pathologic happenings. Of all the varied types of starvation, the complete deprivation of water leads most rapidly to a fatal termination.

Under many circumstances the sensation of thirst is sufficient to help maintain near its optimum the balance between water intake and output that insures the greatest well being. Now and then one hears persons make reference to the "flushing of the kidneys" or some related pseudoscientific term without any real comprehension of what is actually involved or wherein it may have any actual physiologic significance. Few persons realize to what an extent common foods are actual carriers of water into the organism. Some of them are actually made up to an extent of 90 per cent or more of water. Furthermore there are potential sources of water in the metabolism and combustion

of the energy-yielding components of the organism. Adolph² has remarked that the water contained in a food is present in several forms, ranging from a pure solvent through water of crystallization, of colloidal hydration and of secondary valence to water combined with carbon to form carbohydrate and the like. Until the conditions are known under which each form of water exists, analytic distinctions must remain arbitrary. The main fact, however, as Adolph has pointed out, is that whenever ingestion becomes impossible it is difficult to supply water fast enough. Rectal administration, gastroclysis, parenteral infusion and subcutaneous infusion are all inadequate for any purpose except temporary or experimental use. It is well known that water may be absorbed directly into the outer layers of the mammalian skin, but the passage of significant amounts inward through the skin does not occur.

One way of attaining a more helpful appreciation of the services actually performed by water in the body is to contemplate the actual rate of turnover that this remarkable solvent experiences every day by various organs of adult persons. Some of these organs and fluids, such as the salivary glands, stomach, intestinal walls, pancreas, liver and lymph, return the water that they draw from the blood. The minimum represented in this way is 3,700 cc, a more liberal estimate is 9,800 cc. In the case of the kidneys, the colon (discharging feces) the skin with its insensible loss, the sweat glands, and in women the mammary glands, the figures for actual total loss of water from the body range from a minimum of 1,050 cc to the liberal figure 7,800 cc. These calculations, made by Adolph, permit one to estimate the total daily water turnover at something between 4,700 and 17,600 cc, representing an actual possibility of more than 4 gallons. It would be difficult to select a more striking quantitative indication of what the physiologic role of water in the organism really means.

In his detailed review of the metabolism and partition of water, Adolph has described the essential relations of the body to water intake. If water is drunk he states, an equal amount is excreted usually within two or three hours in the urine, in addition to the water excreted at the normal rate. Meanwhile the insensible loss of water increases in rate, so that the body often ends up by having as little water as it would have had if none had been ingested, if not less. The same result is obtained from drinking a solution of almost any salt in a concentration that is isomolar with the blood. But if the salt is sodium chloride or sodium bicarbonate, little or no diuresis results and the excess fluid is eliminated slowly (during twenty-four or forty-eight hours). If protein, carbohydrate or fat is taken with the water certain amounts of the fluid are retained and stored with the food until the food becomes os-

² Adolph E. F. *The Metabolism and Distribution of Water in Body and Tissues*. *Physiol. Rev.* 13: 336 (July) 1933.

ized If the water is taken before food, it will be promptly excreted, if it is taken with or soon after the food or salt, it may be retained If water alone is taken, particularly after the excessive loss of salts, as by sweating, the dilution of the tissues may be sufficient to bring on intoxication or cramps

Dehydration has come to be regarded as a serious medical problem under certain circumstances Its occurrence is being more generally recognized, particularly in infancy Adolph has pointed out that dehydration resulting from low water intake or other processes produces many effects that are quite obvious The sense of thirst normally detects dehydration first but is readily interfered with by experimental or pathologic conditions The superficial signs of lack of water are dryness of the skin, shrinkage of subcutaneous tissues, decreased deformability of skin, and decreased rate of urinary excretion Diminution of blood volume and shrinkage of other tissues follow What is an adequate water supply? The most obvious test, Adolph insists, is to give a large quantity of water by mouth and to see whether any of it is retained, or at least whether the urine becomes diluted In most cases this indicates whether or not the body is "saturated" Changes in body weight may be used to detect the retention of water Most physiologists will agree with Adolph, however, that all measurements of the state of the body with respect to water must be relatively empirical until the mechanisms of regulation are better understood

HOSPITALS AND THE DEPRESSION

The depression has placed a serious additional burden on hospitals and clinics that minister to the poor The poor have increased in number, funds to meet the costs of their care have decreased What were the hospitals to do? There were two alternatives They must either increase their revenues or cut their costs The former has been in most instances impossible To reduce costs without thereby curtailing the quantity of service afforded or endangering its quality has been extremely difficult Though many unbalanced hospital budgets and depleted unrestricted endowment funds mark the efforts of hospitals to meet the situation, various other means have also been tried Most hospitals have lowered salaries and wages not once but two or three times They have done this not because hospital trustees have felt that their employees were overpaid but because this was an immediately effective way of reducing costs Thus hospital employees have had to bear more than their fair share of the costs of the increased load placed by the depression on the shoulders of the institutions in which they work In addition to wage reductions many hospitals have culled from their payrolls personnel who could perhaps be spared without impairing essential service to patients Some have depleted their social service departments and have given up well baby clinics routine health examinations

examinations for child placement, and other preventive and educational activities Some private hospitals have restricted their outpatient service to those patients who could pay their nominal charges, referring those who could not to municipal hospitals and clinics Some have reduced the period of hospitalization of obstetric patients to seven, five, or even three days following delivery, arranging with nursing organizations to give further after-care in the patients' homes Others have more rigidly restricted their admissions to those who are acutely ill

The necessity of practicing rigid economy has not been without a modicum of value to hospitals No doubt it has led many hospital administrators to give greater attention to the business aspects of their job Lavish expenditures for nonessentials are being curbed The building of hospitals that are not needed and the inordinate decoration and furnishing of those that are to be built have at least temporarily ceased

Efforts were made by various organizations to secure portions of state and federal appropriations for the unemployed and their dependents for the hospitals Most of these efforts have been futile Though there has been some assistance to hospitals from public relief funds in a few states, the Federal Relief Administration made it clear from the start that it would not permit the allocation to hospitals of any of the money at its disposal This position was taken, no doubt because of the inadequacy of the appropriation in relation to the immensity of the task If the way out of the present economic situation is to be marked by a rise in commodity prices, the plight of the hospitals will be still sorrier for a period Though more patients will eventually be able to pay their bills, increased costs of the goods they consume will be experienced by hospitals long before there will be an appreciable increase in their revenue from patients Most hospitals have in one way or another weathered the storm thus far The communities they serve must see to it, however, that they are neither wrecked nor disabled if the gales continue to blow

THE RESPIRATOR IN EPIDEMIC POLIOMYELITIS

The management of acute epidemic poliomyelitis presents many serious difficulties calling for a variety of clinical experience and technical skill in their successful solution After the epidemic character of the disease became clearly recognized in this country, the pressing problem seemed to be the treatment of the resulting paralysis This is probably what might be expected because of the conspicuous nature of this symptom and its distressing effects on the patient It was presently learned that damage may sometimes be done to the paralyzed patients by the institution of measures that are too energetic Draper¹ has said that it is far better

¹ Dr. George Henry Melrose, in Cecil's Textbook of Medicine, 1910, published by W. B. Saunders Company, 1910.

to err on the side of inaction than to begin massage and passive motion too soon. Fortunately, great progress has been made in the treatment of the paralyzed parts.

Of late the threatening symptoms of the respiratory embarrassment due to poliomyelitis have come into prominence. The introduction of apparatus to promote intrapulmonary exchange of air sufficient to maintain life has become widespread, especially since the development of the Drinker respirator,² now most frequently used for respiratory failure. After reporting the results of the employment of this apparatus in a considerable number of cases at the Willard Parker Hospital, New York, Brahdly and Lenarsky³ conclude that the Drinker respirator represents a decided advance in the treatment of respiratory failure in poliomyelitis. With improvement in the apparatus and in the technic of treatment, the mortality among patients who would die of respiratory failure should be greatly decreased. The time has arrived to ascertain the shortcomings as well as the merits of such promising therapeutic methods. The New York investigators observe that the medical and nursing care of the patient aside from the artificial respiration, must be kept in mind. The timely administration of sedatives and parenteral injections of fluid, laxatives or other medication will avoid interference with the artificial respiration. As it is not possible to tell whether a patient will need treatment in the respirator for a few days or for several weeks the paralyzed skeletal muscles require attention. Until the apparatus and technic are improved Brahdly and Lenarsky do not advise the treatment of patients with slight or moderate respiratory distress in the respirator. Repeated small doses of sedatives and continued reassurances, they state, will make such patients comfortable and enable them to rest but a patient with involvement of the respiratory muscles should be in a hospital near a respirator, because there is no way of telling whether or not the condition will become worse.

The spinal lesions characteristic of poliomyelitis by no means present a highly unfavorable prognosis,⁴ but when there are bulbar lesions associated with the more vital centers the outlook is not encouraging. Today the problem of when to initiate the use of the respirator perhaps occasions the most serious debate, for respirators are so expensive that the number available at any one institution is limited, and during an epidemic only the patients with the most urgent cases can be treated. For the same reason it would be impossible to give more than a few patients prolonged treatment in the respirator after they had regained the use of their respiratory muscles. Of course, respiratory failure is not the only cause of death in poliomyelitis.

Current Comment

TRANSMISSION OF COMMON COLDS BY FOOD

The possibility that common colds may be spread by fomites has been suggested by epidemiologists, but convincing experimental proof has not been available. The recent demonstration by Bliss and Long¹ of Johns Hopkins University that contaminated food may transmit this disease to chimpanzees therefore, is significant. Fifteen apes were kept for three months under scrupulous quarantine conditions. All attendants were examined daily for infections of the upper respiratory tract and remained healthy throughout the experiments. The attendants wore masks and gowns and took full aseptic precautions in preparing food and taking care of the animals. During this preliminary period the fifteen apes remained free from infections of the upper respiratory tract. At the end of the period a person suffering from a common cold was allowed to prepare food for the animals. After the food was placed in aseptic containers by this person he left the kitchen. The attendant then entered, carried the containers to the quarantine rooms and placed them in the individual chimpanzee cages. Within forty-eight hours after the first meal five of the apes developed typical symptoms of infection such as nasal discharge, nasal obstruction, mouth breathing, slight fever, and leukocytosis. Two developed a moderately severe cough.

FEDERAL MEDICAL RELIEF AND EMPLOYEES' COMPENSATION

Four million persons have been placed within the last few weeks under the coverage of the Federal Employees' Compensation Act. The mechanism of this new phase of governmental activity is described under Government Services in this issue of *THE JOURNAL*. For every injury and occupational disease sustained in the performance of duty, all the four million are entitled to medical and hospital service at government expense. For disability or death resulting from such injuries and diseases, they or their surviving dependents are entitled to compensation. This army of employees has been hired and put to work, many of them in strange fields, without medical examination or approval. The possibilities of the situation, present and future, require the serious consideration of the medical profession. Under the cover of emergency activities the government is enabled to undertake actions that would not be assumed in less feverish times without extended hearings by all the elements of the population concerned. Physicians view with alarm this gradual transmutation of medical practice into a function of government bureaucracy. History indicates that measures introduced in an emergency tend to be perpetuated by the bureaucrats developed to make them effective during the emergency. The medical profession requires some assurance that these new invasions of medical practice by the government are to be truly emergency measures in the strictest sense of that term.

Association News

MEDICAL BROADCAST FOR THE WEEK

Talks over Network of the National
Broadcasting Company

The American Medical Association broadcasts each Monday afternoon from 4 45 to 5 o'clock, Eastern standard time (3 45 central standard time) There will be no talk on Monday December 25, or on January 1 The next talk over the National Broadcasting Company network will be on January 8

Radio Talks from Station WBBM

The American Medical Association broadcasts on Tuesday and Thursday mornings from 8 55 to 9 o'clock, central standard time, over Station WBBM (770 kilocycles, or 389.4 meters)

The subjects for the week are as follows

December 26 Children's Parties
December 28 Who Knows More Than the Doctor?

There is also a fifteen minute talk sponsored by the Association on Saturday morning from 9 45 to 10 o'clock over Station WBBM

The subject for the week is as follows

December 30 Plastic Surgery

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES NEW HOSPITALS EDUCATION PUBLIC HEALTH ETC)

CALIFORNIA

Personal—J Harold Williams, Ph.D., professor of education, University of California at Los Angeles, was elected president of the Southern California Society for Mental Hygiene recently—Dr Howard Morrow, San Francisco, has been appointed president of the California State Board of Health, succeeding Dr John H Graves, San Francisco, resigned

Heart Committee—Dr Gordon E Heim was named chairman of the San Francisco Heart Committee during its annual meeting, November 23, Dr John J Sampson, vice chairman, and Dr Jay Marion Read reelected secretary Fifty-five cities of California were represented at the annual heart symposium, November 22-23, and the total attendance was 655

Committees on Cancer Education—A program of cancer education for the lay public will soon be inaugurated by the Cancer Commission of the California Medical Association, according to a recent announcement Committees will be appointed representing each county society and these with the state commission will furnish speakers for meetings Local publicity will be handled by the county committees

Dr Evans to Give Herzstein Lectures—The fourth course of the Morris Herzstein lectures will be delivered at the San Francisco County Medical Society by Dr Herbert M Evans, Morris Herzstein professor of biology University of California Medical School, January 29 and 31 and February 2 Dr Evans will speak on 'Internal Secretions of the Anterior Lobe of the Pituitary Body' The lectures are given under the auspices of the medical schools of the University of California and Stanford University

COLORADO

Hospital Meeting—Dr John Andrew Longmont was chosen president-elect of the Colorado Hospital Association at its annual meeting in Denver November 15-16 Mr Guy M Hamner is president Dr George Walter Holden a former president and Mr George A Collins Denver for many years a member of the association were made life members at this meeting

Society News—At a meeting of the El Paso County Medical Society, November 8 Drs George H Stine Colorado Springs spoke on 'Treatment of Strabismus' and William C

Black Denver, "Agranulocytosis"—The Mesa County Medical Society was addressed in Grand Junction recently by Dr Edward H Peterson on "Cirrhosis of the Liver" and Mr Robert Whipple, "Aschheim-Zondek Test for Pregnancy"—Dr Cecil H Darrow, Denver, spoke before the Pueblo County Medical Society in Pueblo, November 7, on "Increasing Use of the Bronchoscope," and Dr Herbert A Black, November 21, "Treatment of Inoperable Carcinoma of the Uterus"

CONNECTICUT

History of County Society—Interesting features in the history of the New Haven County Medical Association are now brought out in prospect of the celebration of the one hundred and fiftieth anniversary of its founding, January 15 The association was the ninth county medical society formed in this country and is the second oldest of those which have been continuously in existence, it is believed Dr Leverett Hubbard, first president of the association, was also first president of the Connecticut State Medical Society, and Dr Jonathan Knight, a member of the county organization, became president of the American Medical Association in 1853 The first medical transactions to be published in this country were issued by the New Haven County Medical Association The records of the association from its first meeting in 1784 to the present time are in a perfect state of preservation and constitute a collection of exceptional interest in the history of medicine, the report says

ILLINOIS

Personal—Dr Otto H Crist, Danville, was elected president of the Wabash Valley Aesculapian Society recently The semiannual meeting will be held in Danville in May—Dr William E Kendall has been appointed chief medical officer of the Edward Hines, Jr, Hospital Hines, succeeding Dr William G Cassels, who has gone to Washington, D C, to serve as a member of the board of appeals in the Veterans' Administration—Dr Harriett Daniel, Murphysboro, has been appointed pediatrician to the state health department, it is reported—Dr David L Bley, Staunton announced his retirement from practice at a dinner, November 14, in honor of his eightieth birthday, newspapers reported He has practiced medicine in Staunton for fifty eight years

CHICAGO

Personal—Dr Harold Hoover has been appointed assistant in medicine in the department of internal medicine, University of Illinois College of Medicine—The University Palms, Grade Officer d'Academie, has recently been conferred on Dr Disraeli W Kobak by the French government, in recognition of his work in physical therapy

Professor Elschnig to Lecture on Cataract Extraction—Dr Anton Elschnig professor and head of the department German University Eye Clinic Prague, Czechoslovakia will conduct a course on intracapsular extraction of cataract, February 27, under the auspices of the Chicago Ophthalmological Society An illustrated lecture early in the afternoon will be followed by operations on patients before groups of not more than ten registrants The registration fee is \$10 Professor Elschnig will address the society, February 26, on "Extraction of the Lens in Myopia" Further information may be had from Dr Theodore M Shapira, 58 East Washington Street

LOUISIANA

Dr Matas Honored—At a ceremony in New Orleans, December 4, Dr Rudolph Matas, since 1928 emeritus professor of surgery, Tulane University of Louisiana School of Medicine New Orleans, was presented with the medal of the Order of Isabella the Catholic, the only Spanish decoration retained by the republic from the late monarchy, the presentation was made by the consul of Spain The honorary degree of doctor of medicine and surgery was also conferred on Dr Matas on this occasion the consul-general of Guatemala making the presentation on behalf of the University of Guatemala The mayor of New Orleans presided at the ceremony and Dr Edward L King president, Orleans Parish Medical Society was among the speakers Dr Matas was professor of surgery at Tulane from 1895 to 1927

Society News—Dr Edgar G Billenger, Atlanta Ga delivered the eighth Stanford E Charile Memorial Oration of the Orleans Parish Medical Society, December 4 on 'Affections and Lesions of the Prostatic Urethra, with Special Reference to Transurethral Resection' Speakers before the society, November 13 were Drs David L Watson on "Use of Iodo-tine Hydrochloride in the Treatment of Infectious Diseases"

Ansel M Caine "Oxygen Therapy" and Sydney Jacobs, "Hyperinsulinism" A symposium on dysentery constituted the program of the society, November 27, with the following speakers Drs Charles W Duval Daniel N Silverman and Charles F Craig and Ernest Carroll Faust Ph D—The Fourth District Medical Society was addressed in Shreveport, November 7 by Drs Carl A Weiss Baton Rouge, and J Garnett Yearwood Shreveport on medical economics Dr Yearwood was elected president

MICHIGAN

Personal—Dr Bernard W Carey, Detroit, medical director of the Childrens Fund of Michigan was elected president of the Michigan Public Health Association at its annual meeting in Lansing, November 9, succeeding Dr William J V Deacon of the state department of health

Illegal Practitioner Fined—Frank J Brimmer, "Indian herb medicine man," pleaded guilty to a charge of practicing medicine without a license, November 2, in Grand Rapids and paid a \$50 fine and costs to avoid serving a sixty day jail sentence, newspapers reported Brimmer admitted prescribing for a woman who, according to a previous diagnosis by a physician, was ill with diabetes The woman's husband stated that Brimmer attempted to make him believe that he also required treatment, it was said

Course in Psychiatry and Neurology—A five day course in psychiatry and neurology for the general practitioner will begin, January 22, under the auspices of the department of graduate medicine University of Michigan Medical School Ann Arbor Emphasis will be placed on the diagnosis and management of the minor psychoses Participating in the course as instructors will be Drs Albert M Barrett, director of the state psychopathic hospital and professor of psychiatry Carl D Camp, professor of neurology Max M Peet, professor of neurologic surgery, and Udo J Wile, professor of dermatology, and others

Society News—Dr Henry Field Jr, Ann Arbor, addressed the Oakland County Medical Society in Pontiac, November 15 on "Treatment of Arthritis"—Drs William V Mullin and Albert D Rudemann, Cleveland discussed allergy, focal infections, multiple sclerosis and retrobulbar neuritis before the Detroit Oto Laryngological Society November 15—Clarence C Little Sc D Bar Harbor Maine addressed the Wayne County Medical Society, December 4 on "A Survey on Cancer"—Drs David J Levy and Wyman C C Cole conducted a round table before the Detroit Pediatric Society November 8 on feeding of the new-born infant—The Kalamazoo Academy of Medicine was addressed November 21 by Drs John L Lavan health officer of Kalamazoo on 'Present-Day Status of Immunologic Sera and Vaccines,' and George L Waldbott Detroit, "Management of the Allergic Patient"—Dr Neil I Bentley, Detroit, addressed the Monroe County Medical Society, November 16 on "Ear Conditions Following Acute Respiratory Infection"

MINNESOTA

Personal—Dr Vernon L Hart formerly of Dayton, Ohio, now of Minneapolis, has been appointed instructor in the department of orthopedic surgery, University of Minnesota Medical School Minneapolis, effective, October 1 Dr Hart is continuing the practice of the late Dr Emil S Geist—Dr Albert E Olson, Duluth, was recently appointed a regent of the University of Minnesota

Radiologic Meeting—The Minnesota Radiological Society held its fall meeting in St Paul, November 11 The following program was presented

Dr Willard L Burnap Fergus Falls Osteochondritis Juvenilis Deformans

Dr Maurice A Shillington St Paul Observations from a Clinical Tour

Dr Kano Ikeda St Paul Pneumonia in Young Infants Associated with the Aspiration of Various Oils

Dr Walter H Ude Minneapolis The Roentgen Diagnosis of Placenta Praevia

R B Wiley MA Rochester NY The Improvement of Chest Radiography

Dr George M Landau Chicago The American Registry of Radiological Technicians

In addition Dr Alfred W Adson Rochester, spoke on 'The Value of Ventriculography and Encephalography to the Brain Surgeons' and L A Carlson St Paul showed a motion picture demonstrating the manufacture of x-ray film

MISSISSIPPI

State Board Lends X-Ray Machine—A philanthropic agency recently presented a portable x-ray machine to the Mississippi State Board of Health, to be sent out from time to time to counties in which there are no x-ray machines Only those who are sent to the chest clinics by physicians or accompanied by physicians will be examined

Resolution on Mosquito Eradication—The Issaquena Sharkey-Warren Counties Medical Society recently adopted a resolution urging the appointment of a committee to study malaria control and the eradication of mosquitoes Declaring the incidence of malaria in and about Vicksburg to be the highest for many years, the society recommended that a committee representing the Warren County Health Department, the Vicksburg Chamber of Commerce, the mayor and aldermen of Vicksburg, the supervisors of Warren County, and the Mississippi River Commission and district engineers work with the malaria committee of the society to achieve the eradication of mosquitoes

MISSOURI

Dr Cannon Gives Hodgen Lecture—Dr Walter B Cannon, George Higginson professor of physiology, Harvard Medical School, Boston, will deliver the annual Hodgen lecture of the St Louis Medical Society, January 9 His subject will be "The Significance of the Emotional Level"

Advisory Committee—An advisory committee of members of the Missouri State Medical Association has been appointed to cooperate with the state board of health Members of the committee appointed by Dr Warren L Allee Eldon, president of the association, are Dr Williams McKim Marriott, St Louis dean, Washington University School of Medicine, Father Alphonse M Schmittalla St Louis, dean, St Louis University School of Medicine Dr Dudley S Conley, Columbia, dean, University of Missouri School of Medicine Dr Arthur R McComas, Sturgeon, chairman, Dr William H Breuer, St James Dr Jabez N Jackson, Kansas City, and Dr Edward J Goodwin, St Louis, ex officio The appointment of the committee was in response to a request of the state health department

Society News—A symposium on inflammation of the female pelvis was presented before the Cole County Medical Society in Jefferson City, recently by Drs Richard P Dorris, Thomas J Kelly, Edward E Mansur and William A Clark—Dr William M Kinney Carthage, gave a paper on "Interpretation of the Normal Chest Roentgenogram" before the Jasper County Medical Society, November 14—At a meeting of the Nodaway County Medical Society in Maryville, November 17, Drs John L Myers and George H Thiele, Jr, Kansas City, were the guest speakers on 'Practical Suggestions for the General Practitioner on Ear, Nose and Throat Work' and 'Diagnosis and Treatment of Anorectal Disease,' respectively—November 28 was designated as "past presidents' night" for the St Louis Medical Society Dr Morris Fishbein Chicago editor of THE JOURNAL, spoke on "Present Trends in Medical Practice"

NEBRASKA

Personal—Dr James T Googe, Meridian, Miss, has been appointed health officer of Lincoln He assumed the office December 1—Dr Archibald R McIntyre, associate professor of physiology and pharmacology at the University of Nebraska School of Medicine, Omaha, has been promoted to a professorship

NEW JERSEY

Tribute to Hospital Head—Dr James F Ackerman president of the board of governors of the Fitkin Hospital, Asbury Park was guest of honor at a testimonial dinner sponsored by the Monmouth County Medical Society, September 14 Tributes were paid to Dr Ackerman by Gov Harry Moore, Mayor Clarence E F Hetrick of Asbury Park, Dr Claude A Burrett dean, New York Homeopathic Medical College, New York Dr Samuel A Brown, dean, New York University and Bellevue Hospital Medical College, Dr Fred Eric J Qungley Union City, president, Medical Society of New Jersey and Dr Robert E Watkins, Belmar, president, Monmouth County Medical Society Dr William G Herrman Asbury Park, was toastmaster About 300 persons attended the dinner

Society News—Dr Roger H Dennett, New York addressed the Bergen County Medical Society, Hackensack, November 14, on 'Everyday Problems of the Pediatrician and

the General Practitioner" The society's program of graduate courses began with a series for November on gynecology given by Dr David Corn at the Hackensack Hospital—Drs Joseph T Beardwood, Jr, and Frederick A Bothe, Philadelphia, discussed medical and surgical management, respectively, of hypothyroidism and hyperthyroidism at a meeting of the Atlantic County Medical Society, Atlantic City, November 10—Dr George Griffith, Philadelphia, addressed the Camden County Medical Society, Camden November 7, on cardiac arrhythmias—Drs Harrison S Martland, Newark, and Charles Norris, New York, and Mr Louis Costuma of the New York City police department addressed the Associated Physicians of Montclair and Vicinity in Bellevue, October 27, on medical methods of dealing with crime

NEW YORK

University News—The University of Buffalo announces competition for its annual award of a gold medal to the author of a paper on an ophthalmologic or allied subject Details may be obtained by writing to the dean of the medical department or to Dr Harold W Couper, 543 Franklin Street, Buffalo, chairman of the committee on award

Health at Utica—Telegraphic reports to the U S Department of Commerce from eighty-five cities with a total population of 37 million, for the week ended December 9, indicate that the highest mortality (20.2) appeared for Utica and that the rate for the group of cities as a whole was 12 The mortality rate for Utica for the corresponding week of 1932 was 11.7 and the rate for the group of cities, 12.3 The annual rate for the eighty-five cities was 10.9 for the forty-nine weeks of 1933, as against a rate of 11.1 for the corresponding period of last year

Society News—Speakers at the annual meeting of the Medical Society of the County of Franklin, Malone, October 30, were Drs William V Cone and David W MacKenzie, Montreal, Que, on "Abscess of Brain—Diagnosis, Pathology and Treatment" and "The Prostate—Its Pathological Aspects and Newer Forms of Treatment," respectively, and Harold H Berman, Ogdensburg, on "Psychoneurosis"—Dr Louis C Kress Buffalo, gave a paper on "Five Year Cancer Cures" at a meeting of the Dutchess-Putnam Medical Society, November 8, in Poughkeepsie—A symposium on neurology was presented by three Syracuse physicians before the Medical Society of Jefferson County, Watertown, November 9, Dr Eugene N Boudreau discussed pathology, Dr Wardner D Ayer, pathology, and Dr Albert B Siewers, clinical manifestations

New York City

New Clinic for Occupational Disease—New York University and Bellevue Hospital Medical College has opened a special clinic for occupational diseases, with a laboratory equipped for the work Cases of lead poisoning silicosis, occupational dermatoses and benzene poisoning have already been handled in the clinic which meets Wednesday afternoons Physicians and industrial health workers have been invited to refer cases

Dr Wynne to Retire as Health Commissioner—Dr Shirley W Wynne health commissioner of New York, has filed application for retirement to take effect December 31 Dr Wynne entered the department in October 1907, as a medical inspector and served as assistant registrar and chief of the division of statistical research up until 1920 when he was named assistant to the commissioner In 1924 he was made director of hospitals In 1926 Dr Wynne was appointed deputy commissioner and on the resignation of Dr Louis I Harris in 1926 he became commissioner

Gifts to Columbia—Recent gifts to Columbia University for medical purposes include the following

Rockefeller Foundation \$29,374 for various purposes \$6,000 for and of studies of the common cold

General Education Board \$4,583.33 toward maintenance of the department of the practice of medicine \$8,000 toward support of the sub departments of tropical medicine

Edward S Harkne \$9,917 toward support of the department of diseases of children

Josiah Macy Jr Foundation \$8,462.50 for the work of various departments

Th Lilly and Company \$2,400 for research in the department of pathology

Commonwealth Fund \$18,000 for research into causes of dental decay

W K Kellogg Foundation \$10,000 for study of rheumatic fever under the direction of Dr Walter W Palmer

National Research Council \$5,000 for special research in the department of anatomy

OHIO

Professor of Anatomy Appointed—Rollo C Baker, Ph D, for many years a member of the department of anatomy at Ohio State University College of Medicine, has been appointed chairman of the department to succeed the late Francis L Landacre, Ph D

Personal—Dr and Mrs Harry W Powers, Amherst, celebrated their fiftieth wedding anniversary, November 29—Dr Floyd R Stump Alliance has been elected health commissioner of Stark County—Dr Seward Harris, Lisbon, has been appointed health commissioner of Columbia County to succeed the late Dr Thomas T Church, Salem

Cincinnati Physicians Install Business Bureau—The Physicians' Business Bureau has recently been organized in Cincinnati, with the approval of the Cincinnati Academy of Medicine, for credit rating of patients and collection of troublesome accounts Dr Louis Howard Schriver, a past president of the academy of medicine, is president of the bureau The academy has recently installed a telephone service to locate physicians and to give information to the public on questions of public health Questions concerning hospitals and other institutions will also be answered

Tuberculosis Week in Columbus—To further education of the public and stimulate activity of the medical profession concerning tuberculosis, the Columbus Academy of Medicine carried out a program, November 13-17 Clinics were held each day at various hospitals for physicians and the public was invited to inspect hospitals and clinics treating the tuberculous, November 16 Dr Jay Arthur Myers, Minneapolis, addressed a meeting of the academy, November 13 on "Modern Aspects of the Diagnosis and Treatment of Tuberculosis" and Dr Edward J O'Brien, Detroit, addressed a dinner meeting, November 17, on "Collapse Therapy in the Treatment of Pulmonary Tuberculosis" Both guests also gave radio talks Dr Myers addressed the physicians at Columbus Preventorium on childhood tuberculosis and Dr O'Brien spoke at a special meeting of the Ohio Sanatorium Association at the Franklin County Sanatorium, on thoracoplasty The Columbus Tuberculosis Society also participated in the activities with demonstrations of dispensary cases

PENNSYLVANIA

Dinner to Dr Falkowsky—The Lackawanna County Medical Society recently gave a dinner in honor of Dr Charles Falkowsky, Jr, Scranton, president of the Medical Society of the State of Pennsylvania during the past year Dr Donald Guthrie, Sayre president of the state society, and Dr Edward A Schumann Philadelphia delivered addresses and Dr Leonard G Redding, Scranton, presented an engraved medal to Dr Falkowsky on behalf of the society Dr Ernest L Kiesel, Scranton, was toastmaster

Secretary for Thirty-Eight Years—The Bucks County Medical Society gave a dinner at Doylestown November 14 in honor of Dr Anthony F Myers Blooming Glen, who has been secretary of the society since 1895 Dr Myers has been a member of the society since 1888 and has missed only four meetings since that time it was said In 1893 he served as president Speakers of the evening were Drs Moses Behrend Philadelphia, president-elect of the Medical Society of the State of Pennsylvania and Wilmer E Krusen, Philadelphia Dr John B Carrell Hathboro, was toastmaster The meeting also marked the eighty-fifth anniversary of the founding of the society

Philadelphia

Navy Hospital Cornerstone Laid—The laying of the cornerstone of the new Navy Hospital was a feature of the annual celebration of Navy Day, October 27 Rear Admiral Charles E Riggs, former surgeon general of the navy, officiated and Rear Admiral Percival S Rossiter, present surgeon general summarized the history of the hospital The Bureau of Medicine and Surgery, Washington D C has the clinical records of the hospital, in which the first entry is dated May 3 1822 The new building will have 650 beds and the total cost is estimated at \$3,200,000

Personal—Dr William E Parke was elected president of the Association of Ex-Residents and Resident Physicians of the Philadelphia General Hospital at the annual dinner December 5 Dr George Wilson was reelected secretary—Dr Emily L Van Loon was recently elected president of the graduate council and alumnae association of the Woman's Medical College of Pennsylvania—Dr Earl D Pond, medical director of the Institute of the Pennsylvania Hospital, has established a fund for mental patients with the \$10,000 accom-

panying the Philadelphia Award for distinctive community service, which he received last February (*THE JOURNAL*, March 4, page 671) —The West Philadelphia Medical Association gave a dinner, November 28 in honor of Dr Moses Behrend, president-elect of the Medical Society of the State of Pennsylvania

Society News—Dr Alwin M Pappenheimer, professor of pathology, Columbia University College of Physicians and Surgeons, New York, gave the annual Gross Lecture of the Pathological Society of Philadelphia, December 14, on "Certain Nutritional Disorders of Laboratory Animals"—Drs Helena E Riggs and Paul Sloane addressed the Philadelphia Neurological Society, December 15, on "Significance of Coloidal Gold Curve in Nonluetic Infections" and "Newer Concepts in the Treatment of Chorea," respectively —Dr George S Crampton, professor of ophthalmology, University of Pennsylvania Graduate School of Medicine, gave an illustrated lecture on the manufacture of ophthalmic lenses, with special reference to bifocals, at the new Franklin Institute December 20 —The Philadelphia Health Council and Tuberculosis Committee announced that the number of cases of tuberculosis diagnosed in its clinics from January through October showed a 17 per cent increase over the same period of 1932

TEXAS

Society News—Dr Elbert Dunlap, Dallas, was elected president of the Texas Association of Obstetricians and Gynecologists at the recent annual meeting in San Antonio, September 30 —The El Paso County Medical Society cooperated with the city-county health department in a campaign of immunization against diphtheria for the month of November The department was to furnish toxoid to physicians and urged parents to send children to the family physician Indigents were to be given free immunization on proof that they were unable to pay a physician —Dr Platt L Allen presented a paper on epidemic pleurodynia at the meeting of the Parker County Medical Society, October 3, in Weatherford —Speakers at the meeting of the Harris County Medical Society, Houston, October 11, were Drs Lloyd U Lumpkin on "Nerve Block Anesthesia," and Herman W Johnson, Robert A Johnston and Henry O Nicholas, Ph.D., on "Eclamptic Toxemia A Consideration of the Poisonous Amnes as a Possible Cause"

WEST VIRGINIA

Heart Association Meeting—The medical department of the University of West Virginia and Monongalia County Medical Society were joint sponsors of a meeting of the West Virginia Heart Association at the university in Morgantown November 28-29 Dr Arthur M Shipley, Baltimore, was the guest speaker at a dinner, Tuesday evening, November 28, on "Surgery of the Heart and Pericardium" Among other speakers at the sessions were the following members of the university faculty: Drs Samuel J Morris, on anatomy of the cardiovascular system; Dr Edward J Van Liere, physiology; Clement C Fenton, bacteriology and pathology of cardiovascular disease, and Norman A David, pharmacology and drug therapy of heart disease Dr Oscar B Biern, Huntington, is president of the association, Dr Raphael J Condr, secretary

WISCONSIN

Society News—Dr M Reese Guttman, Chicago, addressed the Fond du Lac County Medical Society, November 8 on mastoiditis and its complications —At a meeting of the Tri-County Medical Society (Juneau-Vernon-Monroe) at Tomah, October 12, speakers were Drs Joseph Dean, Madison, on arteriovenous aneurysms, Fred W Gaarde, Rochester, Minn, allergy, and Paul A O'Leary, Rochester, dermatology —Dr Avery D Prangen, Rochester, Minn, addressed the Rock River Eye, Ear, Nose and Throat Society, October 17, in Beloit, on new methods in surgery of the eye

District Meetings—The Seventh Councilor District Medical Society held its annual meeting at La Crosse, November 8 Medical and surgical clinics were held at La Crosse hospitals in the forenoon and a program of addresses in the afternoon Speakers were Drs Ralph M Waters and John W Harris, Madison, on anesthesia in obstetrics, Jay Arthur Myers, Minneapolis, diagnosis and treatment of pulmonary tuberculosis, Walter C Alvarez, Rochester, Minn, types of nervous indigestion, and Stanley Seeger, Milwaukee, treatment of burns —Dr Kellogg Speed, Chicago, was guest speaker before the Ninth Councilor District Medical Society, Wausau November 8 on "Unhappy Results in Treatment of Fractures"

GENERAL

Dr Adams Elected President of Chemical Society—Roger Adams, Ph.D., since 1926 head of the department of chemistry, University of Illinois, Urbana, has been chosen president of the American Chemical Society Professor of chemistry at the school since 1919, Dr Adams' special interest has been in organic chemistry, particularly local anesthesia and chaulmoogra oil derivatives He was associate editor of the *Journal of the American Chemical Society* for many years and was awarded the William H Nichols Medal in 1927 Dr Adams was a member of the Federal Committee on Synthetic Drugs during the World War

Society for Study of Arthritis—The fifth annual meeting of the American Society for the Study of Arthritis was held in New York, December 8, with the following program

Dr Reginald Burbank, New York Brief Historical Resume Leading to the Present Concept of Arthritis
Drs William H Park and Anna W Williams New York Bacteriology of Rheumatoid Arthritis and Allied Conditions
Dr Lazaros G Hadjopoulos New York Correlation of Findings in Specific Etiology of Rheumatoid Arthritis
Allan Winter Rowe Ph.D Boston Disturbed Liver Function as a Complication in Arthritis
Dr Charles F Tenney, Jr New York Artificial Fever Produced by the Short Wave Radio and Its Therapeutic Indications

Association for Advancement of Science—At the winter meeting of the American Association for the Advancement of Science in Boston, December 27-30, the section on medical sciences will devote the first two days to symposiums on pneumonia, sociology and medicine, tuberculosis, appendicitis and typhoid carriers The section will meet jointly with the American College of Dentists, December 29, and with the American Society of Parasitologists, December 30 Dr Charles R Stockard, New York, vice president for the section, will deliver his address Wednesday morning, December 27, on "The Internal Secretions and Genetic Quality in Structural Development"

Dr Jessup Becomes President of Carnegie Foundation—Walter Albert Jessup, LL.D., has resigned as president of the State University of Iowa to become president of the Carnegie Foundation for the Advancement of Science, it was announced, December 13 Henry S Pritchett, LL.D., president emeritus of the foundation, has been acting president of the foundation since the death in September of Henry Suzzallo Sc.D Dr Jessup became dean of the College of Education at Iowa in 1912 having been associated with the University of Indiana in a similar capacity He became president of the University of Iowa in 1916 His resignation is expected to become effective, May 1 1934

Student Health Association—The fourteenth annual meeting of the American Student Health Association will be held in Chicago, December 28-29, at the Hotel Stevens, under the presidency of Dr Dean F Smiley of Cornell University, Ithaca, N.Y. The program includes addresses by the following physicians

Dr Alfred Adler New York Individual Psychology and Education
Dr Jay Arthur Myers Minneapolis Treatment of Tuberculous Students
Dr Arville O DeWeese Kent Ohio Adjustment of Instruction in College Hygiene to the Informational Level of Students
Dr Edward V L Brown Chicago Eye Problems of Students
Dr William G Leaman Jr Philadelphia The Heart and Athletics
Dr Elizabeth E G Whitney San Francisco Personality Problems of College Women
Dr Robert T Legge Berkeley Calif Development of Facilities to Remedy Physical Defects at Student Rates
Dr Oliver S Ormsby Chicago Common Skin Diseases and Their Diagnosis
Dr Gladys Dick, Evanston Ill Control of Scarlet Fever Among Adults
Dr Harold D Palmer Philadelphia Mental Hygiene Problems in a University

There will be a symposium on prevention and treatment of athletic injuries, presented by Drs Joseph E Raycroft, Princeton, N.J., Marvin A Stevens, New Haven, Conn., and Lewis K Ferguson, University of Pennsylvania At the annual association luncheon, Thursday, December 28 Dr Morris Fishbein, Chicago, editor of *THE JOURNAL*, will speak on "Student Health Service and the Medical Practitioner"

Society News—Dr Hugh Leslie Moore, Dallas, Texas, was elected president of the Southern Medical Association to succeed Dr Irvin Abell, Louisville, Ky., at the annual meeting in Richmond, Va. November 17 Vice presidents elected were Drs Fred M Hodges, Richmond, and Thomas A Groover, Washington, D.C. The 1934 session of the association will be held in San Antonio, Texas —Dr Arville O DeWeese, director of student health service, Ohio State College, Kent, Ohio, was elected president of the American Association of School Physicians at the annual meeting in Indianapolis in

October Dr William A Howe, Albany N Y, is secretary
—The next annual meeting of the National Tuberculosis Association will be held in Cincinnati, May 14-17, 1934 Saranac Lake has been designated the place for the session in 1935
—The American Social Hygiene Association has recently conducted a series of institutes for Negro physicians for demonstration of technic in diagnosis and treatment of syphilis in Savannah, Ga., Charleston, S C, and Jacksonville, Fla Dr Walter J Clarke of the New York staff directed the institutes in cooperation with local health and medical authorities—Dr William S Middleton Madison, Wis, was elected president of the Central Society for Clinical Research at its recent meeting in Chicago Dr Lawrence D Thompson St Louis, was reelected secretary

Bequests and Donations—The following bequests and donations have recently been announced

Central Maine General and St Mary's General hospitals Lewiston Maine \$5000 each by the will of Edward H Delano of Lewiston
Harvard Medical School Boston \$50000 under the will of the late Dr Jeremiah J Corbett
Presbyterian Hospital \$121 647 and New York Post Graduate Hospital and Medical School \$30000 by the will of the late William Colgate Montefiore and Sydenham hospitals New York \$5000 each by the will of the late Henry A Dix
Hospital of the Servants for Relief of Incurable Cancer Hawthorne N Y, \$50000 under the will of the late Rebecca O Burehmal
Presbyterian Hospital Philadelphia and West Jersey Homeopathic Hospital Camden N J \$5000 each under the will of the late Mrs Edith B Cunningham, Philadelphia
Mount Carmel Hospital Columbus Ohio \$4000 Children's Hospital and Franklin County Sanatorium \$1000 each by the will of the late Elizabeth F Schmidt
Mansfield General Hospital Mansfield Ohio \$10000 by the will of Charles A Ritter
Episcopal Hospital Philadelphia \$2000 under the will of Marianna B Griffiths
Huron Road Hospital Cleveland \$100000 by the will of Mrs Mary E Wickham
St Luke's and St Mary's hospitals Duluth Minn \$7000 and \$5000 respectively, by the will of the late August Fitger
Lenox Hill Hospital New York \$25000 by the will of the late Heinrich E F Sandhagen
Middlesex General Hospital New Brunswick N J and Morristown N J Memorial Hospital, \$5000 each by the will of Mrs Caroline McElann Johnson
Memorial St Luke's and Children's Homeopathic hospitals Philadelphia \$2000 each and Northeastern Hospital \$1000 under the will of John Henry Gallati
Stuyvesant Square Hospital \$5000 and St Vincent's Hospital New York \$2500, from the estate of Raymond Blackwood
University of Pennsylvania Philadelphia \$10000 under the will of the late Mrs Louise M Holroyd for cancer research

Orthopedic Meeting—The second annual meeting of the American Academy of Orthopedic Surgeons will be held at the Palmer House in Chicago January 8-10 The first day will be devoted to seminars, the second to papers and the third to clinical presentations of cases and end-results There will be symposiums on fractures, bone tumors and equalization of lengths of legs Conducting seminars will be Drs Lewis J Pollock, Chicago, Carl Wiggers Cleveland George E Brown, Rochester, Minn, Mont R Reid Cincinnati, Louis G Herrmann, Cincinnati, Geza De Takats, Chicago Earl R Carlson New York Walter O Klingman New York Dallas B Pheister, Chicago, and Richard H Jaffe, Chicago Papers will be presented by the following physicians

Frank E Curtis Detroit Decancellation of Os Calcis Cuboid and Astragalus for Correction of Club Foot
Walter Bauer Boston Blood Calcium Studies in Orthopedic Conditions Including Parathyroid Disorders
Garry De N Hough Jr Springfield Mass End Results of Study of 130 Cases of Hip Flexion Deformity Due to Poliomyelitis
Vaughan Dunn Birmingham England Stabilization Operations in Poliomyelitis with Especial Reference to Feet
Arthur Steindler Iowa City Pott's Paraplegia
Emuel D Smith Milwaukee Fractures of the Femoral Shaft Maintenance of Reduction and Fixation by Means of Drilled Metal Screws Immediate and Continued Ambulation
Joel E Goldthwait Boston Recognition of Skeleton Atrophy in the Cause and Treatment of Fractures of the Spine and Hip with Especial Reference to Nonunion
John D Camp Rochester Minn Roentgenographic Evidence of Spinal Cord Tumors and Bone Lesions Due to Parathyroid Disturbances
Marius A Smith Petersen Boston Internal Fixation of Fractures of the Neck of the Femur
Henry Heyward Wescott Roanoke Operation for the Internal Fixation of Transversal Fractures of the Femur
Alph B Chormley Rochester Minn Low Back Pain with Sciatica The Facet Syndrome
John S Coulter Chicago Local Applications of High Frequency Current (Medical Diathermy)

Dr Morris Fishbein Chicago will be toastmaster at the banquet and make the presentation of a medallion to the outgoing president Dr Willis C Campbell Memphis Tenn Gordon J Laing LL D Chicago will speak following the banquet on The Medicine Man Ancient and Modern—Are Doctors Human

FOREIGN

Society News—The French Medical and Scientific Alliance was recently founded by physicians interested in research for the purpose of holding meetings of research workers, honoring those whose work contributes to progress in medicine and encouraging young workers to devote themselves to research Information concerning the new society may be obtained from Dr Claoue, 39, rue Scheffer, Paris 16

Eastman Dental Clinic in Brussels—The cornerstone for the George Eastman Dental Institute of Brussels was laid at a ceremony, October 20 Dave H Morris, American ambassador to Belgium, and Harvey J Burkhart, DDS, representing the Eastman interests, were present as Queen Elizabeth signed the charter and sealed it in the cornerstone It is expected that the building will be completed in 1934

International Congress on Rheumatism—The fourth International Congress on Rheumatism will be held in Moscow, May 3-6 1934 Subjects to be discussed are clinical aspects of rheumatic fever, indications for balneologic treatment of rheumatic patients, rheumatism in transport workers, mine workers and metal workers and the occupational factor in rheumatic diseases in the light of experimental results Further information may be obtained from the headquarters of the International League Against Rheumatism, Keizersgracht 489 Amsterdam, Holland

Publications on Malaria Wanted—The director of the Central Malaria Library created by the Stazione Sperimentale per la Lotta Antimalarica in 1925 requests that all malarialogists send to it books, reports and articles on malaria in order that the library may be made as complete as possible Photostat copies of any articles in the library may be obtained at the cost of production All publications and requests should be addressed to the Director at the station, Corso Vittorio Emanuele, 168, Rome (116) In addition to the photostat service, the station issues each year an index to malaria literature

Personal—Prof Jules Gonn Lausanne France, received the William Mackenzie Medal of the Royal Faculty of Physicians and Surgeons, Glasgow, October 13, in recognition of his contributions to ophthalmology, especially in the treatment of detachment of the retina He delivered the William Mackenzie Memorial Lecture on "The Evolution of Ideas Concerning Retinal Detachment Within the Last Five Years"—Dr Richard Atkinson Stoney, Dublin, has been elected president of the Royal Academy of Medicine of Ireland, succeeding Dr Thomas G Moorhead—Dr R F Guymer Surrey, England, received the Sir Charles Hastings Clinical Prize for 1933 awarded by the British Medical Association for a study entitled "Tonsillectomy—Before, During and After"

Government Services

Federal Medical Relief and Employees' Compensation

A new phase of governmental entrance into the practice of medicine has developed by a gradual evolution First came payment for medical services, but not for hospital services, for destitute unemployed persons, by the federal government through state relief administrations Next destitute unemployed persons were put to work, on state payrolls, through grants of federal money, at wages assumed to be sufficient to enable them to provide medical and hospital services for themselves and their dependents Now these employed men estimated at two million in number are transferred to federal payrolls—and two million more men will be added The wages are regarded as sufficient to enable the workers to live in decency and comfort yet they receive also the medical and hospital benefits conferred on federal employees by the United States Employees' Compensation Act of 1916, for diseases and injuries arising out of the performance of duty

The Federal Emergency Relief Act approved May 12 1933 created the Federal Emergency Relief Administration charged with the duty of making grants to the several states to aid in meeting the costs of furnishing relief and work relief and in relieving the hardship and suffering caused by unemployment By the National Industrial Recovery Act approved June 16 1933 a Federal Emergency Administration of Public Works was authorized to prepare a comprehensive program of public works including projects of the character theretofore constructed or carried on either directly by public authority or with public aid to serve the interests of the general public and with a view to increasing employment quickly to construct

finance or aid in the construction or financing of any public works project included in the program thus prepared. Because of the magnitude and the nature of the task assigned to the Federal Emergency Relief Administration of Public Works, unexpected delay occurred in putting to work, for the purpose of increasing employment, the money that had been provided for that purpose. The President, therefore, November 7, created the Federal Civil Works Administration and appointed Harry L. Hopkins as Federal Civil Works Administrator. Mr. Hopkins occupies also the position of Federal Emergency Relief Administrator. To the newly created Federal Civil Works Administration the Board of the Federal Emergency Administration of Public Works allocated from public works funds \$400,000,000 to enable it to provide regular work on public works at regular wages, for unemployed persons able and willing to work. Employees under this plan are to be hired by state and local civil works administrations set up by the administrator as federal agencies, without investigations into the financial status of the persons employed, in an effort to meet the needs of the many destitute unemployed men and women who are willing and eager to work but who are not willing to have their names entered on relief rolls.

The four million men and women hired by the Federal Civil Works Administration are to be employed on projects of a character heretofore carried on by public authority or with public aid, to serve the interests of the general public. The projects undertaken must be of such a character as to be socially and economically desirable and must be susceptible of being undertaken quickly. They are described by Public Works Administrator Ickes as projects on the borderline of public works. Among the projects suggested are the construction of parks and play grounds, the repairing of roads, the building of feeder roads, the extending of sewer systems and water mains and general activities in the field of sanitation exclusive of such work as collecting garbage, cleaning streets, removing snow and cleaning parks. While the work is to be decentralized as far as practicable, the agencies, state and local, through which it is undertaken are to be regarded as federal agencies and the money used for the work a part of a federal appropriation is to be disbursed by federal officers. The money used in any state is not a grant to the state but in determining the amount that is to be expended in any state a formula is to be employed that takes into consideration the population of the state and the number of persons on the relief rolls. The expenditure of this appropriation within a state will not prevent the allocation of federal funds to that state for direct relief.

Wage rates are to vary. No maximum rates are fixed. The minimum rate for unskilled labor in the South is 40 cents an hour and in the North 50 cents an hour. In the South, skilled labor is to receive not less than \$1 an hour, and in the North not less than \$1.20. Rates of pay must in any event be such as will with a thirty hour week enable an employee to live in decency and comfort. These wages it is assumed, will enable every employee to pay for such medical service as may be needed by him and those dependent on him. If, however, an employee because of the stress of circumstances is unable to do so he may apply to the state or local emergency relief administration for aid, including medical services. Since employees on the rolls of state and local civil works administrations are hired by and through federal agencies and paid from a federal appropriation, they are within the purview of the Federal Employees' Compensation Act and are entitled to medical and hospital services at government expense if they are injured or develop disease in the course of their employment. The administration of that act as it applies to these employees is under the United States Employees' Compensation Commission and the rules applicable to compensation for federal employees generally are applicable with but slight modifications to employees on the rolls of the Federal Civil Works Administration.

Employees are entitled to treatment for only such injuries as they sustain in the performance of duty and for occupational diseases. Diseases that do not show a direct causal relationship to the employee's work, and injuries not sustained in the performance of duty, do not entitle the employee to medical and hospital treatment at public expense. The fact that a disease develops while an employee is engaged on a civil works project is not of itself sufficient to entitle him to treatment. If there is doubt as to whether the disability of an employee is due to an injury sustained in the performance of duty or to disease contracted in that manner the local civil works administrator is to send the disabled employee to a United States medical officer or to a designated physician, with a request for treatment and is to take immediate steps to determine the origin of the disability. Reasonable medical, surgical and hospital services and supplies are to be provided, and such transportation as is

necessary to that end. Government regulations contemplate treatment at medical establishments maintained by the federal government. Where adequate federal medical facilities are not available, other public medical facilities, state, county or municipal, may be utilized. The United States Employees' Compensation Commission has designated, too, some four thousand physicians to render medical treatment where no government establishments are available. Where either government medical facilities or such designated physicians are available, they must be employed. Where they are not, local civil works administrators may arrange for medical care by such reputable physicians as will agree to charge only stipulated fees. Physicians designated by the Federal Employees' Compensation Commission and private physicians and hospitals specially employed are to be paid fees not in excess of those charged patients in the same income class as the injured person. Osteopaths and chiropractors may be employed only when recommended by the government or by designated physicians. The Federal Employees' Compensation Commission keeps postmasters and the larger establishments of the federal government informed concerning government and designated medical facilities and any official or employee can obtain information concerning them from the local postmaster.

An employee may refuse the medical or hospital treatment proffered by the government but if he does so the government will not pay for the medical or hospital services that he provides for himself. An employee treated by his private physician or in a private hospital selected by him must report from time to time to a United States medical officer or to an officially designated physician, for examination to determine whether or not his disability continues. An injured or ill employee seeking treatment at government expense must leave with the physician or hospital from whom he receives service a written request from the local civil works administrator that such service be rendered and a blank voucher. Bills for service cannot be paid in the absence of such authority. If it has been impracticable however for an employee to obtain such a request a medical officer or a designated physician may give temporary treatment provided proper authorization be obtained from the employee's official superior within forty-eight hours. Unless such authorization is obtained, the medical officer or designated physician has no authority to give further treatment at public expense. Vouchers for services, accompanied by a copy of the official request for them are to be transmitted to the Federal Employees' Compensation Commission for settlement. A separate voucher is to be submitted for each employee treated on the form provided for that purpose. Vouchers should be verified by the signature of the employee whenever practicable and in all cases they must be certified by the local works administrator.

Physicians desiring to have their names placed on the list of physicians authorized by the Federal Employees' Compensation Commission to treat federal employees suffering from injuries or diseases caused by the discharge of their duties, in places where United States hospitals and dispensaries are not available or are inadequate, should make application to the Federal Employees' Compensation Commission, at Washington, D. C. It has not been the policy of the Commission to designate an indefinite number of such physicians in any one locality, but changes are made necessary from time to time by deaths, resignations and changes of physicians' residences, and with the present increase in the number of federal employees entitled to treatment, an increase in the number of designated physicians seems inevitable. It will be well, however, for any physician who contemplates accepting any such designation to learn the requirements of the commission with reference to examinations, treatment, records and reports, and to learn the rates of compensation allowed by the commission in his community, before he does so.

Toxicologist Wanted

The U. S. Civil Service Commission invites applications for toxicologist positions of various grades to be filed before January 11. At present there is a vacancy in the position of assistant toxicologist in the Bureau of Chemistry and Soils, Department of Agriculture with headquarters in San Francisco. The entrance salary for this position ranges from \$2,600 to \$5,400 a year less a deduction of not to exceed 15 per cent as a measure of economy and a retirement deduction of 35 per cent. Competitors will not be required to report for a written examination but will be rated on their education and experience. Full information may be obtained from the Civil Service Board of Examiners at any postoffice or customhouse in any city or from the U. S. Civil Service Commission, Washington, D. C.

Synthetic Vitamins Versus Natural Foods

Dr H A Harris, professor of clinical anatomy at University College and author of 'Bone Growth in Health and Disease' has done research and shown that the transverse lines on the long bones, which are usually ascribed to rickets, are due to temporary cessation of growth. He criticizes in the *Times* the prescribing of synthetic instead of natural foods. He quotes a pioneer of physiologic chemistry, Prout who in 1831 maintained, in his Goulstonian lecture, that 'nature will not permit the chemist to officiate as her journeyman even in the most trifling degree.' Professor Harris thinks that before the community is asked to exchange natural cod liver oil, with its richness in vitamins A and D, for synthetic preparations much more reliable information must be provided as to the effect of calciferol on the other stigmas presented by the rickety child. Milk, eggs, butter, cheese and adequate proteins rich in essential amino acids are still required for the maintenance of growth and health in the child. There are no substitutes for a generous all round diet of fresh food. This is as fundamental as the second law of thermodynamics. Professor Harris holds that rickets is a disorder of growth which appears essentially during the three main springing up periods of life—almost exclusively in the first two years of life and rarely in the years associated with the eruption of the second teeth or with puberty. The infantile starvelings of the slums with their chronic malnutrition are not growing fast enough to acquire rickets. The extent of malnutrition cannot be gaged by the prevalence of rickets. The extent of the cure and healing of rickets cannot be gaged solely by the improvement in the roentgenographic appearance of the bones. Vitamin D probably does all that is wanted as regards calcification of cartilage and possibly even bone formation. This is true not only in human rickets but also in the leg weakness of chicks. But other vitamins are necessary for growth, normal development and resistance to infection.

The Minimum Necessary Expenditure on Food

Concern has been expressed whether in the present period of industrial depression the unemployed and the poorer paid workers are suffering from malnutrition—whether their purchasing power is sufficient to procure adequate food for themselves and their families. Socialist politicians who are always bent on increasing the dole regardless of the consequences to the state loudly proclaim that there is considerable malnutrition among the poor. Realizing the national importance of nutrition the British Medical Association set up a special committee to determine the minimum weekly expenditure on foodstuffs that must be incurred by families of varying size to maintain health and working capacity and to construct specimen diets. The committee included such well known dietitians as Dr Robert Hutchison and Profs S J Cowell and V H Mottram. It placed on record its regret that there exists no satisfactory routine method by which the nutritional condition can be assessed and the observations of different observers compared. The absence of a satisfactory standard of normal nutrition probably explains why so many divergent opinions are expressed as to the nutritional condition. The committee holds that 3000 calories daily in the food as purchased is sufficient for the average man provided his energy output is trifling. In Scotland it was found that 3700 calories was necessary for prisoners doing moderately hard work. It might be argued that the

unemployed man can keep healthy on 3000 calories, but it is held doubtful whether he can maintain working capacity on this, the necessary number lies somewhere between 3,000 and 3,700. As some figure must be taken for purposes of calculation, the committee took 3,400 calories as purchased which should assure 3,000 available calories. The figure is not a minimum nor on the other hand, is it set up as an optimum. It is slightly lower than the 'standard ration' for the army at home stations. The figure taken for an adult woman is 2,840. For children, Cathcart's table was followed. It begins with 1020 for children aged 1 and under 2 years and rises to 3,060 for ages 12 to 14. It is laid down that from 10 to 15 per cent of the daily calories should be derived from protein (about 100 Gm). Of this amount, 50 Gm should be first class (i.e., animal) protein, the other half may come from vegetable sources. The amount of fat daily is laid down as 100 Gm, as much as possible from certain animal sources. The calories can be brought up to the 3,400 by 500 Gm of carbohydrate, the cheapest source possible. With regard to vitamins it is recommended that if there is any doubt as to their sufficiency in the dietary a few drachms of cod liver oil of certified vitamin content be included. This will insure the requisite amount of vitamins A and D.

Examination of working class budgets shows that the average housewife, with no knowledge of dietetics, purchases food which broadly approximates the dietaries of physiologists. When she has not enough money to buy what she wants, she avoids complaints of hunger from her family by buying less of expensive proteins and fats (such as butter) and more of the cheap carbohydrates—bread and potatoes. A common fault in the dietary of young children is shortage of first class protein.

The committee gives a large number of diets suitable for a man, wife and three children aged, respectively, 1 to 2 years, 2 to 3 years and 3 to 6 years. The cost works out at about \$5 a week.

PARIS

Nov 6 1933

Congress on Renal Insufficiency

Under the chairmanship of Professor Lemierre, the Congress on Renal Insufficiency met recently at Evian, with an attendance of more than 800. One rarely sees a scientific meeting at which a more complete development of a subject is secured. The subject for discussion was rather restricted, nevertheless, fifteen papers were presented and each one dealt fully with its phase of the subject. Professor Castaigne and Dr S Chamerliac discussed azotemias of extrarenal origin, of which they distinguished three types. Professor Villaret, Justin Bezançon and Rene Fauvert described the mechanical role of the liver in the conveyance and distribution of water through the organism. Mr Isod Bennett of London analyzed the changes in blood calcium occurring in renal insufficiency. He attributed the diminution which is constant to the retention of phosphorus, which develops somewhat parallel to the retention of urea. Mr Guy Laroche dealt with purely azotemic chronic nephritis which he thinks is an indication for a diet low in nitrogen and for diuretic treatment. Professor Merklen of Strasbourg discussed recent research on chlorides in nephritis and the indications for rechloridation which is indicated only in certain cases of acute nephritis with true leukopenia and an elevated or normal alkali reserve. It is indicated in the presence of repeated vomiting and diarrhea and has rendered more service to surgery than to medicine even in the absence of nephritis. A paper by Prof Charles Laubry and Mr Walser on permanent arterial hypertension and disorders of renal functioning was one of the most important presented at the congress. The conclusion reached was that there is no necessary relation between these two conditions. Many cases of hyper-

tension are independent of all renal changes, functional or anatomic. Many renal attacks are not associated with hypertension. There are, however, cases in which the two states coexist, sometimes the hypertension precedes and sometimes it follows the nephritis. Only in the latter event can one speak of the relation of cause and effect, but such cases are rare. To summarize: Hypertension results from multiple causes, the kidneys may contribute to the condition but they cannot produce it by themselves. William S. Hoffman of Chicago considered the mineral metabolism in a number of cases of nephrosic edema and reviewed the relation of the changes in sodium, potassium and chlorine to the water retention and the secretion of urine. The paper of Pasteur Vallery-Radot and Pierre Delafontaine dealt with tests of provoked diuresis in the exploration of renal insufficiency. Paul Savy, Henri Thiers and Rene Peycelon of Lyons gave a critical study on the treatment of anuria due to acute nephritis: intravenous injections of hypertonic solution of dextrose, venesection with transfusion of noncitratated blood, injections of hypertonic solution of sodium carbonate, rechloridation, and renal decapsulation. This was the paper that most interested the Societe des eaux d'Evian, which had organized this congress, but the assembled scientists devoted only one paper out of fifteen to this subject.

Congress on Photography in the Sciences

The Association pour la documentation photographique et cinematographique dans les sciences organized a congress, which met, October 7, in the halls of the Musee pedagogique. Photographic and cinematographic documentation are assuming an increasingly important role in biologic instruction. There is scarcely a meeting in which some speaker does not illustrate his paper with a film. Films showing bacteria as the causative agents of infectious diseases are frequently shown to the public, in motion picture houses. Progress has been made in this field by the adaptation of the motion picture to the microscope and this congress furnished abundant proof of that fact. There was also an instructive exhibit of equipment. The congress was under the patronage of Mr. Comandon who made at first film showing the spirochete of syphilis attacking the blood cells. Dr. Clauue and Mr. Jean Painleve, son of the mathematician who became an eminent statesman and whose death has just been announced, promoted the congress. Mr. Comandon, at present attached to the department of inventions, exhibited one of his first films showing, in slow motion, the growth of vegetables. Mr. Yokota of Japan showed the movement of the intestinal contents in animals, the film having been made through an abdominal opening. Mr. Pascals of Paris showed the technic of immediate reduction of recent fractures. Jean Painleve presented the Daphnia and the sea-urchin, showing the possibilities of photomicrography in direct and in indirect light. Mr. Terrien illustrated his operation for cataract, Jacob Sarnoff of New York described, with the aid of a film, cultivation of tissues, de Lee of Chicago illustrated a cesarean operation, Jean Louis Faure explained a subtotal hysterectomy, and Mr. Garripuy of Toulouse showed a normal confinement and a Porro operation. Delherm, Thoyer-Rozat, Fishgold and P. Godet explained a new method of recording the movements of organs by means of roentgen rays, which enables one to study the heart beat. Dr. Gros of Cambrai spoke on the value of making photographic copies of rare books and protested against the heavy tax imposed on them, which often prevents bringing to the public interesting documents in the libraries.

Death of Professor Calmette

Prof. Albert Calmette, assistant director of the Institut Pasteur de Paris, died, after a brief illness, at the age of 70. He began his career as a ship's physician, then in 1890, he entered the colonial medical service and almost immediately began to

do research in the laboratory of Pasteur, who later sent him to Saigon to establish the first Pasteur institute in Indo-China. Calmette returned to France in 1893 and was appointed director of the Institut Pasteur in Lille, then, in 1919, he became assistant director of the Institut Pasteur de Paris, succeeding Metchnikoff. He was a member of the Academy of Medicine and of the Academy of Sciences and had been honored with the Grand Cross of the Legion of Honor. He was known throughout the world for his magnificent research on antivenom serum and preeminently for the BCG vaccine against tuberculosis. He was occupied, when death overtook him, in studying the effects of cobra venom in infinitesimal doses on experimental cancer. In 1911, he published his *Traite d'hygiene*.

French Congress of Otorhinolaryngology

The French Congress of Otorhinolaryngology was held in Paris. The chairman, Professor Chavanne of Lyons, in his address, emphasized the need of an extensive knowledge of general physiology and pathology in the training of the specialist, and deplored the fact that today, diplomas in otorhinolaryngology are bestowed following the completion of short courses of a few weeks. Dr. Lafite-Dupont of Bordeaux presented a paper on the medical and general treatment of acute infections and septicemias in otorhinolaryngology. He discussed the use of serotherapy, vaccines, shock methods, fixation abscess, sodium nucleinate, colloidal metals, soaps, suprarenal organotherapy and radiotherapy, all applied after the focal infection has first been removed as completely as possible and after local vaccination according to the Besredka method. Laval of Toulouse, Barraud of Lausanne, Morcaux of Nancy, Portmann of Bordeaux, Mignon of Nice, and others, presented special communications on the same subject. Louis Leroux, Mr. Baldeux and Mr. Canuyt discussed the interventions in phlegmons of the tonsils and the tonsillar region. Mr. Ramadin presented a paper on the second topic, Deep Osteitis Petrosa. He discussed the anatomic conditions that favor extension of the infection to the meninges, the possible localization of the osteitis, the habitual slowness of the evolution, and the treatment, which should always be surgical and succeeded by drainage. This paper was followed by a general discussion. Other communications were devoted to posttraumatic deafness (Maurice Bouchet), superior tracheotomy (Gault), early diagnosis of cancer of the esophagus and radium therapy (Gusez), and sinusitis.

Reorganization of German Spas

Although balneology in Germany is far advanced, there has been a lack of unity in the relations of the scientific societies. It was evident that a reorganization was needed, and Prof. Dr. H. Vogt of Pyrmont was entrusted with the task. The Deutsche Balneologische Gesellschaft, of which Vogt has been made chairman, will bear in the future, the name Deutsche Gesellschaft für Bader- und Klimakunde. It will be the representative scientific organization of the region and will promote balneologic and climatologic science to as high a level as possible. A close contact will exist also with the fundamental branches of medicine. A further task is the supplying of additional training for spa physicians in scientific practical and ethical matters. The annual assemblies will therefore no longer be held in spas or health resorts but in winter (when patients make fewer demands on their time) in association with universities, clinics and hospitals or in collaboration with other large scientific societies. Courses of lectures will be organized in the medical societies of the large cities on balneologic and climatologic subjects. A scientific committee for the advance-

ment of balneology and climatology will be created, which will give advice to the directorate in professional matters. The *Ständesverein der reichsdeutschen Badeärzte* will continue to function, likewise the *Deutsche Gesellschaft für Rheumabekämpfung*. The need of greater uniformity and a more centralized organ has given rise to a new journal, *Der Balneologe*, the first number of which will appear January 1 (Prof. Dr. Vogt, editor, Julius Springer, publisher).

Nature Cure Societies and the Medical Profession

The nature cure physicians are coming in the "third reich" more to the front than formerly. Not only have the nature cure practitioners formed an organization characterized by reasonable uniformity with special spokesmen for various specialties, but the new leadership of the medical profession has taken a different attitude toward them (*THE JOURNAL*, December 9, p. 1892). A new decree of the commissar of the public health service of the Free State of Saxony is illustrative of this new trend. "After the victorious triumph of the national-socialist revolution and the assumption of leadership by the national-socialist league of physicians in all questions pertaining to public health, it becomes the duty of the medical profession under national-socialist leadership to study more intensively and in a more scientific manner the theories and teachings of the followers of popular medicine. What previous generations of physicians have neglected, we as national-socialists must seek to remedy. I therefore decree for the members of the national socialist league of physicians of Saxony that they must seek membership in the nature cure associations, homoeopathic societies, biochemical societies, Kneipp societies and the like and acquaint themselves in the atmosphere of these societies with the curative methods of popular medicine."

The Age Groups in Health Insurance

According to a report of the federal bureau of statistics, the number of benefit claims of all kinds arising in 1931 in 698 federally organized *krankenkassen* was 1332 for each hundred men and 1421 for each hundred women. Whereas, among the men the youngest age group 14-19 presented claims equal in number to about the average number of members in that group, the next following age groups, 20-24 and 25-29, presented claims equal to 135 and 53 per cent, respectively, in excess of the number of members belonging to those groups. In the age group 30-34 the benefit claims arising during the year were less than the total number of members in that group. From then on there is a gradual reduction, the lowest figures being reached in the oldest age groups 65 and beyond, which lie 12.0 and 19.4 per cent under the average number of members. The relatively slow reduction in the 50-65 age group shows an acceleration in the group above 65 years of age. That may be due to the fact that persons who after the age of 65 are still pursuing gainful occupations constitute a group that is in a peculiar manner productive and resistant. The benefit claims presented by the women members of the *krankenkassen* show a similar development but with more marked differences in the various age groups. The age group presenting the largest number of benefit claims does not go so far beyond the average number of members in the group as does the corresponding group among the men but the women of the 20-35 age group report sick more frequently than the average. From then on there is a gradual decline in the number of benefit claims which is interrupted by an increase during the climacteric (50-54 age group). After that the number of benefit claims presented by the women members decline more rapidly than in the men of corresponding age. The number of cases of incapacity for work per hundred benefit claims arising in the various age groups show slight fluctuations other than in the two oldest age groups of the men. In general there were among the men

29.9 cases of incapacity for work, per hundred benefit claims, and, among the women, 25.1 cases of such incapacity. Up to age 65, the women presented fewer days of incapacity for work than the men.

According to reports of 166 communal *krankenkassen*, the total number of members as of Sept. 1, 1933, was 4,538,845, of which number 2,422,528 were men and 2,116,317 were women. On that date the percentage of members incapacitated for work was 2.68, or 2.31 per cent among the men and 3.06 per cent among the women.

Abandons Cutaneous Tests in Hay Fever

At a recent session of the Vienna Medical Society, Dozent Dr. Urbach discussed modern methods of treatment in the troublesome condition known as pollinosis, or hay fever. Successful diagnosis and treatment presuppose an accurate knowledge of the plants of a given region and the time of their florescence. Dr. Urbach recommends the creation of a hay fever calendar in which one can record the time of florescence of all the plants of a given region that are known to be involved in the production of hay fever. The disease-producing substance is the protein contained in the pollen, although some authors contend that it is the fat substance of the pollen. Doubtless the offending toxin is attached chiefly to the globulin. Many patients are affected by the perfumes, or emanations, from the blossoms. It is interesting that hypersusceptibility to pollen is transmissible. In making an examination to discover the specific susceptibility of a patient, Dr. Urbach applies a tampon of cotton saturated with a fresh 20 per cent aqueous pollen extract to the mucosa of the nasal septum and leaves it five minutes in situ. He has abandoned the "cutaneous test." If the nasal septum test is positive, an acute catarrhal condition of the nasal mucous membrane, attended with a discharge from the nostrils, develops and continues for from five to fifteen minutes. In central Europe, testing with grass pollen extracts is usually sufficient, in many other regions the pollen of tree, bush and flower blossoms must be included. Dr. Urbach no longer uses for treatment the subcutaneous injection, such as was formerly in vogue, but applies a peroral method. In order that researches in this field may be prosecuted on a large scale, the ministry of agriculture has placed at the disposal of the Vienna dermatologic clinic (where Urbach is carrying on his experiments) a large terrain near Vienna, with many plowed fields in the immediate vicinity, in order that the allergic laboratory of this clinic may obtain sufficient grass and blossom material with which to combat in an active manner this now so frequent disease.

The Treatment of Myoma

In one of the regular lectures at the Vienna 'medical seminar,' Professor Halban described the treatment of myomas that is followed by nearly all the leading gynecologists of Vienna. Speaking generally, a much less energetic treatment is applied today to myomas than formerly, for it is now known that they are relatively harmless tumors which frequently occasion little or no discomfort. Only in the event of pronounced indications is active treatment advisable. As such indications may be considered, primarily hemorrhages, menorrhagia or metrorrhagia, in such cases hydrotherapeutic treatment, hot vaginal lavages and ergotine preparations will usually give good results. But if conservative treatment fails, a surgical operation or irradiation is to be considered. Professor Halban usually preferring the former. Such an intervention will reveal whether possibly a hidden neoplasm is causing the hemorrhages. In the case of larger myomas curettage is of

no avail, the results are uncertain, and hence it is to be rejected. The statistics for Vienna show, in 2 per cent of the cases, a combination of myoma with carcinoma of the cervix, in 24 per cent, a combination with carcinoma of the corpus uteri, and in 12 per cent, a combination with sarcoma. Pains associated with myoma arise often as a result of tension, pressure or necrosis, which affect the tissues adjacent to the tumors. If conservative methods are not soon effective it is advisable to resort soon to an operation or to irradiation. Fever usually develops when necrotic processes or secondary infections of the myoma nodules appear and it constitutes an indication for operation. The size of the myoma is not usually an indication the essential thing is the amount of discomfort it causes. The situation is different if the myoma is growing rapidly, as this fact justifies the suspicion of a neoplastic degeneration and points to operative removal, even though no essential pain or discomfort is complained of. In spite of multiple and large tumors, conception is possible. Active intervention is therefore necessary only in case a pregnancy is desired but does not occur after a long period and there is no other apparent cause for the sterility. The combination of myoma and pregnancy is not regarded as an indication for operation if the pregnancy is taking a normal course. Only in case pain (through rapid growth of the myomas) or fever (necrosis) occurs should the myoma be removed—possibly in a conservative manner, in order not to embarrass the pregnancy. If the myoma constitutes a hindrance to birth it should be removed *intra partum*. If the myoma produces a tendency to miscarriage it should be operated on. So called remote effects of a myoma are not infrequent, for instance gastrointestinal disturbances headache even epileptiform conditions which completely disappear after an operation. Professor Halban holds the view that it is justifiable to remove myomas if the abdomen must be opened for any other cause provided the intervention is not thereby delayed too long. This indication is applicable especially to women who live in remote regions where suitable aid cannot be promptly secured. These are, then in general the criteria that justify the attending physician in abandoning conservative treatment of myoma. If none of the indications mentioned are in evidence, a myoma should not be operated on or irradiated.

Operation for Endarteritis Obliterans

Thrombo-angitis obliterans or endarteritis obliterans has been but little subjected to operative therapy. Dr Mandl presented at the last session of the Gesellschaft der Aerzte a patient, aged 34, who for fourteen years had suffered from pain and from intermittent claudication in the left leg. An ulcer appeared which refused to heal, so that a Leriche operation on the femoral artery was performed. Nevertheless amputation of the toes became necessary, and later the lower leg had to be removed. In 1930 the right leg became involved in the same manner. A Leriche operation was performed but the result was not satisfactory. The pulse could be found in the dorsalis pedis only at times, and the pain continued. Dr Mandl decided to perform a retroperitoneal central sympathetic operation (after Rovl, Adson-Brown Stahl). He pushed the abdominal organs to one side also the ureter, and reached retroperitoneally the anterior surface of the vertebral column, where he removed the ganglions of the sympathetic nerve, together with the truncus sympathicus, from the second to the fifth lumbar vertebra. The result after eight months is still excellent the pulse of the dorsalis pedis is strong and continuous, the trophic ulcer, which had become very large healed completely within six weeks while the foot is warm. Of course, one cannot speak of a permanent recovery.

During the discussion, Dr Starlinger of the second surgical clinic reported three cases in which this method of treatment

was applied and in which the results are still good after seven, ten, fourteen and seven months, respectively. He emphasized that in this operation careful hemostasis and ligation of the minute lumbar veins are necessary.

The Increase of Medical Students

The rector of the University of Vienna has announced that the winter semester has brought a marked increase in the number of students. As compared with 1,200 new entrants in the summer semester of 1933, there have been thus far 1,500 new entrants enrolled for the winter semester. The lecture halls are entirely inadequate for the large number of lectures. For instance, the first medicochemical institute which must be attended by the first and second year medical students, can furnish the facilities only by holding an overflow session in another hall, in which the lecture of the professor delivered in the regular auditorium is made available to the overflow session by means of loud speakers, while an assistant performs the corresponding experiments and gives the demonstrations. In spite of warnings the increase in the ranks in medicine are constantly increasing possibly because the other liberal professions offer in our small country still less chance of success. The university authorities are compelled greatly to limit the number of foreign students matriculating for the first two years of the medical course, in order to reserve for Austrian students the facilities in the institutes and the classes in anatomic dissection.

Progress of Cremation in Vienna

In 1922, an ordinance was passed in Vienna permitting human bodies to be cremated instead of being buried in a cemetery. Previously, up to the time of the revolution that grew out of the war ecclesiastical and political considerations had exerted greater influence than arguments based on reason. The first year after the establishment of the Vienna crematory, Feb. 17, 1923 835 bodies were cremated and the ashes placed in suitable urns. The following year, 1,424 bodies were cremated, the next year, 1,880 and since then there has been a steady increase so that now from 12 to 15 per cent of all dead bodies are cremated or about 3,500 annually. At first the Jewish clergy raised objections to cremation but these objections have been withdrawn. Before a body can be cremated permission must be secured at the central police station, in order to prevent criminals from destroying traces of their crime.

Marriages

WILLIAM RAY MCGINTY Moultrie Ga to Mrs Myrtle Marsh of Jacksonville Fla at St Augustine Fla October 29

EARL W BAILLY Bunker Hill Ind to Miss Mildred M Fish of Toledo Ohio, in Luck, Ohio November 29

GEORGE GLASGOW CHILES Sanford, N C to Miss Mae McClellan Gilmore of Olney Md November 16

SAMUEL T BUCKMAN Wilkes-Barre Pa to Miss Catherine Jones of Glen Summit Springs August 10

PAUL THOMAS MCBEE Bakersville, N C to Miss Ivy Sandy of Burkeville Va October 25

JESSE MCCALL Tazewell Va, to Miss Louise Richardson Peggall of Richmond November 18

HARRY JOHN FAUSEL to Miss Lydia A Schmidt both of Chicago at Cincinnati, November 30

WILLARD B CARPENTER to Miss Margaret W Fisher, both of Columbus Ohio November 30

ROBERT DONNELL HAIRE to Miss Mary Ethel Gilbert both of Roswell N M November 14

WILLIAM E BROWN to Miss Sara Price, both of Macon, Ga, October 14

Deaths

Benjamin Franklin Zimmerman, Louisville, Ky, Louisville Medical College, 1901, member of the Kentucky State Medical Association and fellow of the American College of Surgeons, past president of the Jefferson County Medical Society, assistant clinical professor of surgery, University of Louisville School of Medicine, served during the World War on the staffs of the City, Deaconess, SS Marv and Elizabeth hospitals and the John N Norton Memorial Infirmary, aged 60, died, November 10, of heart disease

Samuel Harley Lyle, Franklin, N C, University of Nashville (Tenn) Medical Department 1883, Vanderbilt University School of Medicine, Nashville, 1893 member of the Medical Society of the State of North Carolina, fellow of the American College of Surgeons, president of the Macon Clay Counties Medical Society, formerly member of the county board of education and state legislature, and mayor, proprietor of a hospital bearing his name, aged 72, died, November 14, of heart disease

Harry Burchard Ballou ♂ Mansfield Depot, Conn, University of Minnesota College of Homeopathic Medicine and Surgery, Minneapolis, 1905, member of the American Psychiatric Association and the New England Society of Psychiatry, past president of the Tolland County Medical Society, on the staff of the Mansfield State Training School and Hospital, aged 57, died November 27, of myocarditis and angina pectoris

James Cole Hancock ♂ Brooklyn, College of Physicians and Surgeons, Medical Department of Columbia College New York, 1889, member of the American Academy of Ophthalmology and Oto-Laryngology, fellow of the American College of Surgeons, consulting ophthalmologist to the Brooklyn State and Coney Island hospitals, aged 68, died, November 27 of heart disease

Noble Price Barnes ♂ Washington, D C, Baltimore Medical College, 1893, fellow of the American College of Physicians, formerly associate professor of materia medica and therapeutics, George Washington University School of Medicine, for many years on the staff of the Casualty Hospital, aged 62, died, November 26 of cerebral hemorrhage

Nathaniel Pierce Walker ♂ Milledgeville Ga, University of Georgia Medical Department, Augusta, 1901, member of the American Psychiatric Association past president of the Baldwin County Medical Society, aged 53, for many years on the staff of the Milledgeville State Hospital, where he died, November 20, of pulmonary tuberculosis

Dero Eugene Seay, Dallas, Texas, Vanderbilt University School of Medicine, Nashville Tenn 1896 member of the State Medical Association of Texas and the American Academy of Ophthalmology and Oto Laryngology, fellow of the American College of Surgeons, on the staff of St Paul's Hospital, aged 59 died November 16

Charles Christian Gethman ♂ Eldora Iowa, State University of Iowa College of Homeopathic Medicine Iowa City 1893 past president of the Hardin County Medical Society, member of the city council and school board, formerly county coroner aged 70, died September 3, in the University Hospital, Iowa City, of diabetes mellitus

Ossian J West, Seattle, Willamette University Medical Department, Salem 1889, member of the Washington State Medical Association and the American Society of Clinical Pathologists, formerly on the staffs of the Providence Columbus Minor and Harbor View hospitals, aged 67, died September 17 of hypernephroma

Paul Whitehurst Greene, Retreat, Pa University of Maryland School of Medicine Baltimore, 1900, member of the Associated Anesthetists of the United States and Canada, medical superintendent of the Retreat Home and Hospital for Chronic Diseases, aged 53 died October 29 of chronic myocarditis

Robert John Gardiner, Kingston, Ont Canada Queen's University Faculty of Medicine Kingston 1891 professor of medical jurisprudence and assistant professor of surgery at his alma mater, fellow of the American College of Surgeons, surgeon to the Kingston General Hospital aged 63 died October 31

Eustace Monett Singleton ♂ Marshalltown Iowa Northwestern University Medical School Chicago 1891 member of

the American Academy of Ophthalmology and Oto-Laryngology, physician and owner of a hospital bearing his name, aged 69, died, November 29, in the University Hospital, Iowa City

Walter D Cross ♂ Corsicana, Texas, Memphis (Tenn) Hospital Medical College, 1891, served during the World War, past president and secretary of the Navarro County Medical Society, formerly on the staff of the Corsicana Hospital and Clinic, aged 66, died November 8, of coronary occlusion and arteriosclerosis

James Brew, Nashville, Tenn, University of Nashville Medical Department, 1899, member of the Tennessee State Medical Association, served during the World War, formerly on the staffs of the Protestant and St Thomas hospitals, aged 61, died, November 25, of heart disease

Charles Edward Sayre, Norfolk Neb, Hering Medical College, Chicago, 1894 College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois 1897, member of the Nebraska State Medical Association, aged 71, died, November 18, of pneumonia

Frank Wise Goodell, Effingham Ill, Butler University Medical Department, Indianapolis, 1880, past president of the Effingham County Medical Society, formerly county coroner, at one time on the staff of St Anthony's Hospital, aged 74, died, November 21

Burton French Weston ♂ Mason City, Iowa, Rush Medical College, Chicago 1891, past president of the Cerro Gordo County Medical Society, on the staff of St Joseph's Mercy Hospital aged 64, died, November 18, in a local hospital, of acute endocarditis

Adam Elmer Diller ♂ Aurora, Ill Northwestern University Medical School, Chicago 1907, fellow of the American College of Surgeons, on the staff of St Joseph Mercy Hospital aged 54, died November 30, in the Copley Hospital, of arteriosclerosis

Charles A Wall, Buffalo, University of Buffalo School of Medicine, 1879 member of the Medical Society of the State of New York, past president of the Erie County Medical Society, aged 80, died, November 4, in the City Hospital, of myocarditis

Walter Jones, New York Hahnemann Medical College and Hospital of Philadelphia, 1893, New York Homeopathic Medical College and Hospital, 1896, aged 64, died September 9, in the Morrisania City Hospital, of diabetes mellitus and bronchopneumonia

Edwin S Anderson, Dover, Del, Homeopathic Medical College of Pennsylvania, Philadelphia, 1866, past president of the Board of Homeopathic Medical Examiners, aged 89, died September 21, of arteriosclerosis and chronic interstitial nephritis

Jacob Philip Schneider, Palmer, Mass University of Vermont College of Medicine, Burlington, 1894, member of the Massachusetts Medical Society, for many years chairman of the board of health of Palmer, aged 66, died November 12

William Dewey Wightman ♂ Los Angeles, Northwestern University Medical School, Chicago, 1926, member of the Associated Anesthetists of the United States and Canada, aged 35 died, December 6 of a self inflicted bullet wound

George Leon West ♂ Newton, Mass, Harvard University Medical School Boston 1894, member of the board of health of Newton, aged 65 on the staff of the Newton Hospital where he died November 18 of heart disease

Frank P McKinstry, Washington N J, Hahnemann Medical College of Philadelphia, 1878, member of the Medical Society of New Jersey past president of the Warren County Medical Society, aged 78, died November 23

Louis Audenried Salade, Central Point Ore, University of Pennsylvania School of Medicine, Philadelphia, 1888 aged 69 died November 14, in the Medford (Ore) Hospital, of ruptured appendix and intestinal obstruction

Howard C Silver, Baltimore University of Maryland School of Medicine, Baltimore, 1888 aged 73, died October 22 at the Church Home and Infirmary, of arteriosclerosis, coronary thrombosis and angina pectoris

William Abner Wakeley ♂ Orange, N J, New York Homeopathic Medical College and Hospital 1868 formerly on the staff of the Orange Memorial Hospital aged 70, died, November 17 of cerebral hemorrhage

William David Senn, Newberry S C, Medical College of the State of South Carolina Charleston 1886 member of the South Carolina Medical Association aged 74 died suddenly November 23 of heart disease

George Clinton F Williams, Hartford, Conn, University of the City of New York Medical Department, 1878, since 1920 president of the state board of public welfare, aged 76, died, November 15, of myocarditis

Roger Williams, Los Angeles, Jefferson Medical College of Philadelphia, 1877, member of the Medical Society of the State of Pennsylvania, aged 83, died, November 20, at Upland, Calif, of cardiorenal disease

Hermann W Strosser, New Britain, Conn (licensed, Connecticut, 1893), member of the Connecticut State Medical Society, on the staff of the New Britain General Hospital, aged 72, died, November 5

John C Twitty, Rutherfordton, N C, Baltimore Medical College, 1892, member of the Medical Society of the State of North Carolina for many years county health officer, aged 64, died, November 6

Andrew H Cowie, Flint, Mich, Saginaw (Mich) Valley Medical College, 1899, member of the Michigan State Medical Society, aged 65, on the staff of the Hurley Hospital, where he died, November 24

Oscar Herman Hahn ♂ Hastings, Neb, Ensworth Medical College, St Joseph, Mo, 1908, on the staff of the Mary Lanning Memorial Hospital, aged 48, died, November 23, of cerebral hemorrhage

William A Adair, Moscow Idaho, Fort Wayne (Ind) College of Medicine, 1883, member of the Idaho State Medical Association, formerly city and county health officer, aged 75, died, September 24

Thomas Edward Duffee ♂ Pawtucket R I University of Vermont College of Medicine, Burlington, 1903, aged 61 died, November 10, in the South County Hospital, Wakefield of pneumonia

John Francis Corbin, Galesburg, Ill, College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1898, aged 63, died, December 1, of bronchitis

George William Dippel ♂ Pittsburgh Western Pennsylvania Medical College, Pittsburgh 1902 aged 54, died November 1, in St Francis Hospital, of acute myelogenous leukemia

William J Weindel, Marion, Va, Kentucky School of Medicine, Louisville, 1897, member of the Medical Society of Virginia, aged 58, died, September 7, of carcinoma of the stomach

Ole E Robinson, Independence, Kan Keokuk (Iowa) Medical College, College of Physicians and Surgeons 1901 member of the Kansas Medical Society, aged 56, died, November 13

Morton William Fraser, Woodlake, Calif, Hahnemann Medical College of the Pacific, San Francisco, 1914, member of the California Medical Association, aged 47, died, October 5

Frank Carlton Williams, Syracuse, N Y, University of Michigan Medical School, Ann Arbor, 1883 aged 75, died November 20, of cerebral hemorrhage and chronic myocarditis

Albert Andrew Guffey, McKeesport, Pa, Western Pennsylvania Medical College, Pittsburgh, 1897, member of the school board, aged 65, died, October 1, of diabetes mellitus

August Carl Bothe, San Francisco, College of Physicians and Surgeons of San Francisco, 1899, aged 67, died, October 23, of carcinoma of the sigmoid and diabetes mellitus

Frederick Samuel Pope, Santa Ana, Calif, Trinity Medical College Toronto, Ont, Canada, 1898, member of the California Medical Association, aged 65, died, October 19

Joseph Allen Wright, Covington, Ga, University of Georgia Medical Department, Augusta, 1879, also a druggist, aged 80, died, August 20, in a hospital at Atlanta

Oscar Victor Lawson, San Francisco, Illinois Medical College, Chicago, 1899, aged 62, died, July 13 in the Agnew State Hospital, Agnew, of chronic myocarditis

Frederick Charles Gray, Bayonne, N J Hahnemann Medical College and Hospital of Philadelphia, 1896, aged 63, died, November 22, of cerebral hemorrhage

Sheftel Jacob Elner, Chicago, University of Illinois College of Medicine, Chicago, 1913, aged 63, died, November 24 of coronary occlusion and angina pectoris

Reinhart L Hild ♂ St Louis, Homeopathic Medical College of Missouri, St Louis 1909, aged 65, died, November 19, of myocarditis and coronary thrombosis

Rosa Engelmann, Pasadena, Calif, Woman's Medical College, Chicago, 1889, aged 73, died, September 2, at the Las Encinas Sanitarium, of carcinomatosis

Albon Ellsworth Bartoo, Pomona, Fla, University of Buffalo (N Y) School of Medicine, 1889, aged 71, died November 30, of heart disease

Louis Fowler Joy, Fulton, N Y, Long Island College Hospital, Brooklyn, 1897, aged 62, died, September 9, in Syracuse, of angina pectoris

Ormond Pinkerton Paulding, Santa Maria, Calif, University of Michigan Medical School, Ann Arbor, 1875, aged 88, died, October 21

THE DEATHS OF CALMETTE AND ROUX

To the Editor—Within but a few days' interval the illustrious Institut Pasteur at Paris has lost its two most distinguished leaders. On October 29, Prof. Albert Calmette died at the age of 70 years and on November 3, Dr. Emile Roux, director of the institute, died at the age of 79 years. This double loss to medical science can be fully grasped only by those interested in the progress of science. By their personal charm and creative genius they seemed surrounded by a preciousness wholly different from that of other mortals.

Professor Calmette's keen intelligence was clearly portrayed in his distinguished looking face. But rarely is one fortunate to encounter such mild and radiant eyes. Pure goodness shone through them and betrayed the presence of an even and placid conscience. Always modest and quiet in his manners, he seemed to exist solely for the interests of science and the welfare of humanity. At all times tactful and exceedingly polite, he presented the type of Frenchman foreigners but rarely encounter and the impression of whom is destined to linger in their mind as something worthy of reverence and praise. His immense service in the interest of science was so ideally matched with an almost excessive modesty that the memory of him will always remain a source of inspiration to those who were privileged to know the man intimately as scientist, humanist, master and friend.

Professor Calmette was director of the Institut Pasteur at Lille during the entire German occupation of that city between 1914 and 1918. His arrest was repeatedly proposed, but the enemy openly admitted that his charming deportment exonerated him completely of any guilt and they allowed him to pursue his medical investigations undisturbed on the one condition that he did not quit the city. By the command of General von Gravenitz, Mme. Calmette was carried away as a hostage to a distant prison camp at Hanover. During this cruel ordeal, Calmette was not allowed any news, either from his imprisoned wife or from his officer son, who fought at the front with the French artillery. During the recent tragedy at Lübeck, in which more than seventy children died following vaccination with a contaminated BCG vaccine, said to have come from Calmette's laboratory and subsequently adjudged by the superior court at Leipzig to have been ill prepared by the German bacteriologists at Lübeck, Calmette commented with remarkable evenness of mind on the cruel assaults made against his character by certain German scientists: "Nobody

Albert Calmette

can fully comprehend the moral torture inflicted on me by this unfortunate tragedy, but I desire to exonerate German science—so preeminent in every sphere—of any blame which needs must fall on the shoulders of certain individuals. At no time during this tragic display of bitter feelings across the Rhine was any bitterness detected in this great and placid scientist, although his friends were fully aware of the fact that behind Calmette's serene outward appearance there resided an exquisite sensibility—indeed a fitting attitude to assume by the man who had been privileged to give the world the antivenom serum which already has saved thousands of lives and who now in later years had succeeded in the development of a method which re-aroused world interest in the eradication of tuberculosis.

Dr. Roux presented an essentially different type of personality. Should one come across Dr. Roux during his walks

through the gardens or the corridors of the Institut Pasteur and without knowing the man, instinctively one would ask himself, "Who is this queer old man?" Here he wandered to and fro as a daily routine, old and gray and poorly clad, stoop shouldered and withal a pathetic, sallow-jaundiced complexion. Perforce he conveyed the impression that being alive was to him a source of grief. But behind this pitiable outward frame hid a highly critical and richly endowed scientific personality, which for the past nineteen years has reverently and sagaciously directed the destiny of the world's most illustrious and important center for medical research.

Dr. Roux was popularly best known for his discovery of the diphtheria toxin and the subsequent preparation of the diphtheria antitoxin. But in spite of an immediate and universal recognition as one of the world's foremost savants, he remained excessively modest. For years he occupied small quarters in the garden of the Institut Pasteur, which served him as office and living room. One was surprised to find in his living room an unpainted wooden table, a few simple chairs and an iron bed of the conventional hospital design. Aside from another small

Pierre Paul Emile Roux

table, loaded down with books and papers, his living quarters were frugally bare. He spent the early part of every morning with the institute superintendent and the remainder of the day with studies and medical research. This routine was assiduously followed year after year without interruption for any vacation. Now and then his closest friends would succeed in luring him to the country, but here he soon became fidgety and longed to return to the institute. He nearly attained the age of 80. Had he but spared his efforts he would easily have reached the nineties, for he was endowed with a strong body in spite of its outward frail appearance. He rarely visited the homes of friends and colleagues and religiously refused to accept invitations to mingle with high society. On rare occasions he attended the sessions of the Académie de médecine. He refused to accept the salary to which he was entitled as director of the institute. "I really don't need the money," he said, "and they give me board, room, light and heat, and whenever I become hungry the maid brings me food. The Institut Pasteur needs the money worse than I do." When he was called out to attend to professional duties in rain or in inclement weather, he was always seen to turn up the collar of the overcoat in hastening to catch the nearest autobus or street car. He would not make use of an automobile. "An auto costs too much and we need the money for scientific work." His extreme modesty and frugality knew no limits. Science and hard work were to him the two most important things in life.

The enormous investigations which Dr. Roux was able to accomplish in the interest of medical science are so extensive that only the expert is aware of their importance. Only a few days before his death, he was told of the passing away of his old friend and colleague Calmette. He became deeply moved by this sad news and repeatedly asked whether the laboratories of Calmette were adequately taken care of. While he himself was struggling with death his thoughts centered about the enormous loss to the institute by the untimely death of Calmette, whom he had wished to become his successor as director. When he was apprised of the earnestness of Calmette's associates to carry on the work in the spirit of their departed master, his peace of mind was restored.

These two eminent savants have shed a luster over French science as few others have been privileged to do since the heroic years of Louis Pasteur. They have served their country and the world faithfully and unselfishly. Modestly and devotedly they have labored for the good of humanity in times when so many forces were at play to destroy our noble heritage of civilization, by every possible means of disillusionment and political strife.

KONRAD E. BIRKHAUG
Institut Pasteur

USE OF SALINE IN SOLUTIONS FOR LOCAL ANESTHESIA

To the Editor—In a recent review of my book on local anesthesia (*THE JOURNAL*, October 28, p. 1418) I am criticized for not advocating the use of physiologic solution of sodium chloride in making up the anesthetic solution. Why should one use it in making up anesthetic solution? I have tried about all the various mixtures advised for the making up of anesthetic solutions in the clinic, in my leg, and in bunnies and bow-wows. There is no difference in the "feel" injected in one's own skin and slides of animal tissue show no injury when plain tap water is used. Clinical experience convinces me that anesthesia is more prompt when a hypotonic medicine is used. Wise boys tell me that theoretically a hypotonic solution is more quickly absorbed than an isotonic or a hypertonic one. Be it remembered that after one dissolves a few tablets of procaine in an isotonic solution it becomes hypertonic. Put into a rabbit's abdominal cavity a procaine solution in water is absorbed more rapidly than is one made up with physiologic solution of sodium chloride. What one wants in local anesthesia is for the tissues to drink up the solution as rapidly as possible. Besides, a saline solution cannot be made in the operating room. If my hospital was located in the middle of the Pacific Ocean I would catch rain water for the making of my procaine solutions. Why should one use physiologic solution of sodium chloride for making up our anesthetic solution? I really want to know.

ARTHUR E. HERTZLER, M.D., Halstead, Kan.

[NOTE—The letter was referred to the reviewer of Dr. Hertzler's book, who writes.]

To the Editor—There can be little doubt that tap water is not the optimal or even desirable solvent for anesthetic drugs. Braun showed as early as 1898 that, when salt solutions of various concentrations are injected intradermally pain followed by anesthesia results. With sodium chloride solutions between 0.6 and 2.5 per cent an indifferent zone exists in which neither irritation nor anesthesia of the dermal wheal is detectable. Later, with the help of freezing point determinations, the optimal, isotonic concentration of 0.9 per cent sodium chloride was advised. It has been erroneously thought that, by adding the procaine salt to this solution a hypertonic concentration results. Procaine hydrochloride is freely dissociated in the salt solution, and when it mixes with buffer solutions of the tissues it completely dissociates into the procaine base and is lipid soluble (Gros, 1910). Thus osmotic pressure of the procaine salt is negligible and the salt can be dissolved in physiologic solution of sodium chloride without becoming hypertonic.

Procaine hydrochloride dissolved in tap water may produce anesthesia slightly more rapidly because in the first place, tap water and distilled water as used by Potain (1869) and Dieulafoy (1870) has well known anesthetic properties which follow an initial burning. This initial burning is naturally abolished by the presence of procaine. Another reason for a more rapid anesthesia with tap water is its increased alkalinity (Chicago tapwater has a pH of about 6.8) compared with a

procaine solution dissolved in physiologic solution of sodium chloride, which has a pH of around 4.85 to 5. That alkaline solutions act more rapidly because of the increased hydrolytic dissociation of the procaine base has been universally accepted as a fact.

For these reasons it is quite understandable that the procaine tap water solution may act faster, although how much faster it acts has not been stated, and from my personal experience the difference, at least in infiltration anesthesia, cannot be great. When "wise boys" have informed Dr. Hertzler that the hypotonic solutions are more rapidly absorbed, they have lost sight of the fact that the anesthetic action of procaine on nerve endings, nerve fibers and cell membranes will depend on its absorption as a base to the lipid film with which they are covered.

From clinical experience it can be stated that procaine tap water or procaine distilled water solutions produce persistent edema, induration or, under unfavorable circumstances, even necrosis. Poorly vascularized subcutaneous fat, when injected (and not overinfiltrated) with procaine tap water, may disrupt the fat cell and leak through the incision for weeks. It is unnecessary to say that not only the fat cell ruptures in the presence of such a hypotonic solution but also the red cell hemolyzes and that in thin skinned individuals a permanent brownish induration will testify to this effect. Dr. Hertzler states that slides of animal tissue show no injury when tap water is used. If that is so, the tissue injected must have been muscle and not subcutaneous fat. And when peripheral nerves are brought in contact with strongly hypotonic solutions, they may suffer irreversible damage. French surgeons in the second half of the nineteenth century injected distilled water freely into sciatic nerves resulting in relief from pain and an occasional foot drop. In performing a nerve block, the use of isotonic solutions is even more important than in infiltration anesthesia.

If Dr. Hertzler's clinic was located in the middle of the Pacific Ocean he could still get a little salt from his cook, unless he believed in a salt-free diet.

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be noticed. Every letter must contain the writer's name and address but these will be omitted on request.

THE COMPLEMENT FIXATION TEST FOR AMEBIC DYSENTERY

To the Editor—We have been requested by the United States Public Health Service to examine all our dining car and restaurant employees to pick up if possible cases of dysentery that might have arisen at Chicago. We are actively cooperating in this work and I have learned very indirectly that there is a Craig test for dysentery but do not know anything definite about it. If you can give me references or lend me reprints I shall be much indebted.

J. M. WAINWRIGHT, M.D., Scranton, Pa.

ANSWER—Col. Charles F. Craig, U. S. Army, retired, and now director of the Department of Tropical Medicine of Tulane University School of Medicine, New Orleans, has done an enormous amount of clinical and research work on amebic dysentery, one phase of which has been the development of a complement fixation test for the diagnosis of amebiasis which, he believes, has practical value as a diagnostic method. The technic of this test is practically the same as that of the standard method of performing the complement fixation test for syphilis used in the U. S. Army laboratories. The chief difference in the technic of the two tests is in the preparation and titration of the antigen used. Craig uses an alcoholic extract of cultures of *Endamoeba histolytica* grown on a modified Boeck-Drbohlav medium. He takes a rich culture of this organism grown on the medium and develops subcultures until there are available at least 120 cultures of the organism for extraction with absolute alcohol. It is necessary to use great care in titrating this antigenic extract for hemolytic qualities, anticomplementary

qualities and antigenic strength. The technic of the test is important and should be attempted only by a trained serologist. The use of the undiluted alcoholic extract of *Endamoeba histolytica* as the antigen makes the test very delicate and subject to extreme error unless the exact technic is followed. The practical value of the test therefore, is limited particularly by the difficulty of preparing and titrating the antigenic extract. Craig described his technic in the September, 1929, issue of the *American Journal of Tropical Medicine*. He reported in this article some of the results he obtained with the test. In the June, 1933 *Journal of Laboratory and Clinical Medicine* he described further observations on the test and reported results obtained in testing 1,000 persons. The test, he says has proved of value in the diagnosis of cases of amebic abscess of the liver unaccompanied by intestinal symptoms also in the diagnosis of apparently healthy "carriers" of *Endamoeba histolytica*, and of those presenting mild symptoms of infection also in the control of antiamoebic treatment. The strongest positive results are usually obtained with the test in carriers who have no symptoms of amebiasis or in persons who have mild symptoms of the infection. In some severe cases of acute amebiasis he found the reaction doubtful or negative although in most severe cases the reaction was positive. Persons infested with other species of ameba or with the intestinal flagellates do not give positive complement fixation with this test unless *Endamoeba histolytica* also is present. Normal persons or those ill with other diseases do not give a positive complement fixation reaction unless they also harbor *Endamoeba histolytica*. The specific complement fixing bodies disappear from the patient's blood serum following antiamoebic treatment and the disappearance of *Endamoeba histolytica* from the feces. In relapsing cases of amebiasis, the test which has been negative during the interval of apparent freedom from ameba again becomes positive some times even before the parasite is again demonstrable in the feces. Unless repeatedly negative for several weeks, therefore a negative reaction does not prove the absence of amebic infection or that antiamoebic treatment has resulted in a cure.

In his article in *THE JOURNAL* July 5, 1930, on the diagnostic value of the complement fixation test in amebic infections, Craig noted that Izar in 1914 used an aqueous antigen prepared by extracting fecal matter containing *Endamoeba histolytica* and liver abscess pus. Others endeavored to confirm Izar's report and were not able to obtain consistent results owing to the weakness of the antigenic extract. Craig believes that by his method an antigen can be prepared which is strong enough to react in the majority of patients infected with *Endamoeba histolytica*.

AMEBIC DYSENTERY IN A CHILD

To the Editor—Would you kindly outline specific treatment for an 8 year old girl with clinical amebic dysentery of four months standing? Please omit name. MD Illinois

ANSWER—In the first place it is necessary to be certain that the child has the pathogenic ameba *Endamoeba histolytica*. Secondly, the extent of tissue damage present particularly of the heart, liver kidneys and lower bowel determines the drug of choice in amebiasis. The child's weight is not given. Assuming that she is suffering from acute dysentery the patient should be given bismuth subcarbonate (the subnitrate should not be used see Roe H E. Methemoglobinemia Following the Administration of Bismuth Subnitrate *THE JOURNAL* July 29 1933 p 352) in one fourth to one-half teaspoonful amounts every time she has a diarrheal or bloody movement. If the liver and kidney function is not impaired she may be given carbarsone (Reed A C Anderson H H David N A and Leake C D. Carbarsone in the Treatment of Amebiasis *THE JOURNAL* Jan 16 1932 p 189) in divided amounts orally not exceeding a total of 300 mg per kilogram over a month's period. The drug may be used also as a retention enema in double this total dosage provided rest periods of a week to ten days are allowed between courses to allow for arsenic excretion. (Vioform N N R (David N A Johnstone H G Reed A C and Leake C D. The Treatment of Amebiasis with Iodochlorhydroxyquinoline *THE JOURNAL* May 27 1933 p 1658) may be given in the same amount orally but is not recommended for rectal use because it causes local irritation. Carbarsone has an additional advantage because of its definite tonic action. (Correspondence *THE JOURNAL* Dec 2 1933 p 1819) Emetine hydrochloride may be used subcutaneously in a total amount not exceeding 10 mg per kilogram if there is an amebic hepatitis or hepatic abscess and provided the heart is watched for evidence of possible injury. The diet should be smooth rich in protein and low in starch content. Members of the child's household should be examined in order to make certain that reinfection does not occur.

AMEBIC DYSENTERY IN PREGNANCY

To the Editor—I have a patient who is pregnant and has amebic dysentery. Kindly send me an article or articles pertaining to this subject the treatment being the question in mind without interfering with the pregnancy. REO M SWAN MD Cambridge Ohio

ANSWER—The patient should be confined to bed and given 0.065 Gm (1 grain) of emetine hydrochloride each day hypodermically and this dose repeated for five or six days. Chmofon should then be given in a dose of 0.75 Gm (12 grains) three times a day for a period of eight days. If this dosage of chmofon causes severe diarrhea after the first two days on which it is taken the dosage should be reduced to 0.5 Gm (8 grains) three times a day. During the treatment the diet should be liquid or semiliquid.

DILAUDID

To the Editor—What is the latest on dihydromorphine hydrochloride five times the potency of morphine non habit forming probably less nauseating originated in the Knoll Laboratories in Germany? Please omit name. MD Texas

ANSWER—Dilaudid is capable of producing the effects of morphine in possibly one-third the dose but it is of questionable advantage, as it is evidently habit producing, several cases of dilaudidism having been observed.

FOSHAY SERUM FOR TULAREMIA

To the Editor—I have a case of tularemia in a woman aged 45. The blood test was positive in a dilution of 160 about the twelfth day of the disease. The manifestations are of the ulceroglandular type with an ulcer on the right index finger and involvement of the regional glands along the biceps and in the axilla. The case is running a comparatively mild course and the temperature is now normal at the end of three weeks. The glands however are still swollen and quite tender although they have not yet broken down. The only definite treatment which I have been able to find in the literature is Foshay's serum and Fisher's article in the *Journal of the Indiana State Medical Association* recommending the use of neosarsphenamine. The statistics on these methods of treatment are very meager and I will greatly appreciate it if you will give me any further information you may have on any specific treatment. Is Foshay's serum available on the market if so where can I obtain it? CLARKE ROGERS MD Indianapolis

ANSWER—The antitularens serum developed by Foshay appears to exert a specific curative effect in cases of tularemia (see Foshay, Lee. An Antiserum for the Treatment of Tularemia *THE JOURNAL*, Nov 4 1933, p 1447). The serum is not available at the present time through trade sources but may be obtained directly from Dr Lee Foshay, Cincinnati General Hospital, Cincinnati.

RECTAL GONORRHEA

To the Editor—What is the best treatment for rectal gonorrhea in a woman? Please omit name. MD, West Virginia

ANSWER—Gonorrheal proctitis is treated daily with a cleansing tapwater enema followed by an instillation of one pint of 1:4000 potassium permanganate, as a retention enema. An occasional oil retention enema may be used. In addition, measures are necessary to eradicate the focus from the genital tract. The cervix in the acute stage is treated with applications of either 2 per cent mercurochrome or tincture of iodine and alcohol. Douches are prohibited.

In the chronic stage cauterization of the cervix with the actual cautery is the procedure most commonly practiced. Not to be forgotten is the treatment of the urethra and Skene's glands by massage and instillations of mercurochrome or silver salts. Condylomata acuminata are treated with the silver nitrate stick or the actual cautery.

PROTRACTED PASSIVE HYPEREMIA IN CARDIAC DECOMPENSATION

To the Editor—From my limited clinical experience and library I am unable to ascertain the exact pathologic changes that would take place in an organ when the veins draining the blood from it are constantly partly obstructed in other words when the organ is constantly engorged with venous blood. Information will be thankfully received.

RUSSEL GWINN MD Missoula Mont

ANSWER—The condition described is practically that occurring in protracted passive hyperemia in cardiac decompensation. The changes depend on the degree of obstruction and the structure of the organ, especially the blood supply. In the liver which receives relatively little arterial blood, venous stasis leads to marked asphyxia which results in death and absorption of the functional liver cells receiving the least oxygen namely those in the center of the lobule. Thus a

large proportion of the liver tissue may be lost, its place being taken by dilated blood channels and sometimes to a slight degree by fibrous tissue. On the other hand, an organ receiving much more arterial blood than is required for its mere nutritional needs, such as the kidney, exhibits but little structural change from ordinary degrees of venous engorgement, although its functional activity is decreased in proportion to the decreased blood flow through its secretory elements. In the lungs, because of their structure, diapedesis and repeated capillary hemorrhages lead to iron pigmentation and some fibrosis, whereas in the spleen a diffuse increase in fibrous and elastic elements are the chief effects.

OTOSCLEROSIS AND ALOPECIA

To the Editor—Will you kindly outline an investigation in an effort to discover the cause of otosclerosis in a man aged 23? What is the status of the treatment of otosclerosis with parathyroid gland in an effort to decalcify the bones of the middle ear? What is the status of the treatment of the various forms of alopecia with pituitary extract? Please omit name
M D Arizona

ANSWER—Up to the present, the actual cause of otosclerosis has not been determined. There have been many theories of the etiology of this condition, and one of these holds that it is due to a disturbance of the endocrine glands. Though nothing positive has been determined, it is well known that there is a definite tendency to hereditary transmission that the condition usually develops in early life, and so on. The *Transactions of the American Otological Society* for the past few years have contained reports of the Committee on the Investigation of Otosclerosis. Funds are allocated to several investigators in this country and in Europe, so that the etiology and pathology of this disease are being attacked on many sides. However, no positive results have thus far been obtained. So far as known, the parathyroid gland has had no effect on the calcification of the bones of the middle ear. As a matter of fact otosclerosis is really an otospongiosis, usually in the region of the foot plate of the stapes, and does not involve the other bones of the middle ear.

It has not been definitely demonstrated that pituitary extract has any beneficial effect on alopecia except in a few cases in which there was apparently some definite deficiency of the pituitary gland.

HERPES SIMPLEX

To the Editor—A man aged 33 well nourished and well developed whose tonsils and adenoids have been removed and whose teeth have been roentgenographed without discovery of infection for the past eight years has had herpes of the lips and dryness of the skin of the face as well as herpes on the upper lip and close to the mouth and herpes in the arch of the left foot. Genito-urinary and gastro-intestinal examinations are negative. The lungs and heart are normal. He had 125 skin allergy tests which were all negative. The face herpes comes in cycles of from seven to ten days. In a chronic case of this type what else should I look for as a cause and what internal treatment is usually indicated?

RUSSELL L. HODGE North Kansas City Mo

ANSWER—Herpes simplex is caused by one of the filtrable viruses, which apparently lies latent in most persons, becoming active when resistance is lowered from any one of many causes. Recurrent herpes simplex is supposedly due to the same cause but explanation of its cyclic recurrence is difficult. Many methods of treatment have been used with success. Calcium lactate, from 2 to 5 Gm, dissolved in hot water, three times a day after meals is often valuable. It may well be supplemented by injections, intravenous or intramuscular of calcium gluconate from every three to five days.

Intramuscular injections of the patient's own blood from 5 to 15 cc every five days, is recommended.

Vaccination with cowpox vaccine, repeated, if necessary, has been helpful.

Ultraviolet ray exposures over the area in which the herpes recurs is recommended. Roentgen treatment, one fourth erythema dose once a week, is highly commended. A course of insulin has been reported as successful, as has the use of cinchophen.

Herpes in the arch of the foot is possible, but ringworm in this area is much more probable. If, on examination of the tops of the vesicles after they have been soaked in 10 per cent potassium hydroxide for from two to seventy-two hours, a fungus is found the lesions should be painted daily with tincture of iodine until they dry up, and then an ointment of 3 per cent salicylic acid and 6 per cent benzoic acid in ointment of rose water should be applied once a day for at least a month after the lesions have disappeared.

BILATERAL CRYPTORCHIDISM AND FACIAL TIC

To the Editor—I have an 11 year old boy with bilateral cryptorchidism who for the past year or so has been developing a tic of the neck and face muscles. The testicles are felt in the inguinal canal and cannot be made to enter the scrotum. In view of the attending psychoneurosis which is becoming more marked should I insist on operative measures to transplant one or both testicles? Do you think the condition of the testicles is a factor in causing the nervous symptoms at this age? What operation would be advisable and from statistics what percentage of cures should one expect? Please omit name and address
M D New York

ANSWER—This patient evidently has two distinct conditions first, a bilateral cryptorchidism, and, second, a tic of the neck and face muscles. In view of the fact that the boy is 11 years old and because both testicles can be felt in the inguinal canal the advice that the patient should be operated on is justified. The two testicles should be transplanted into the scrotum at the same time. The operation, if correctly performed, is successful and the patient is cured in every instance.

The tic in the muscles of the neck and face has nothing to do with the cryptorchidism and therefore will not be influenced by the operation. This requires separate treatment by a neurologist.

RECURRENT SWELLING OF LIPS

To the Editor—I have a patient a man about 55 years of age, whose upper lip swells very much occasionally several times a year. Yesterday the patient awoke with the upper lip greatly swollen and about noon it went down and the swelling shifted to the lower lip. This change was very rapid occurring in about an hour. The patient had his upper lip swell when he was a small boy and says that he was treated for worms. Once in a while he suffers terrible itching in the anus and it swells internally and almost closes up. A purgative relieves this condition. Will you please give a diagnosis and treatment? Kindly omit name.

M D South Carolina

ANSWER—From the history, this patient has recurring swellings of the lips similar to a group of cases described in *The Journal* by Drs New and Kirch, April 22, page 1230. The condition is similar to what is known as angioneurotic edema, and permanent enlargement of the lips may result. The treatment suggested is the injection of boiling water in multiple areas about the lips and the use of radium externally with distance and screening.

B ACIDOPHILUS IMPLANTATION

To the Editor—1 Is it possible for an anhydrous milk preparation to contain the living organisms of acidophilus bacilli? 2 What is the minimum number of acidophilus bacilli that must be ingested daily in order to have an acidophilus bacillus implantation take place in the colon? Kindly omit name
M D, New York

ANSWER—1 An anhydrous milk might possibly contain some living acidophilus bacilli but in the ordinary process of preparation and handling of dried milk their occurrence is not at all likely.

2 It is difficult to state the minimum number of living acidophilus bacilli that is necessary for implantation. Bacillus acidophilus milk should contain at least 100,000,000 viable organisms per cubic centimeter, and from a pint to a quart of such milk is required daily to effect results.

DISAPPEARANCE OF SPERM AFTER VASECTOMY

To the Editor—A North Dakota physician asks how long it takes for spermatozoa to disappear from the semen after a bilateral vasectomy. Your answer is that one or two ejaculations should be sufficient. I have had occasion to do a number of these operations and in order to satisfy myself about the question involved I had condom specimens brought to the office for microscopic examination until the semen was undoubtedly clear of spermatozoa. I found that the first specimen obtained after operation contained as many as usual the second contained about half the number found before operation the third contained several the fourth a few and the fifth an occasional organism or none. I never found any after that but I advise patients not to depend on the certainty of disappearance until a few more ejaculations have occurred. One who examines the interior of the seminal vesicles or even a picture of a longitudinal section will realize that there is some uncertainty as to just when the last tiny spermatozoon may be eliminated or when those already ascending the vas above the point of section may have reached the vesicle and then have been discharged.

HEREDITY IN HYDROCEPHALUS

To the Editor—In view of the recent communication from Dr Madge T Maclean (*The Journal* Nov 18 1933 p 1663) concerning the occurrence of several hydrocephalic children in the same family, I thought that you might be interested in the hereditary hydrocephalus of the mouse now being bred and studied at Harvard. In these mice it behaves as a mendelian recessive which is probably the mode of transmission in some human cases.

Book Notices

Colds and Hay Fever By Frank Coke FRCS Cloth Price \$2 Pp 148 Baltimore William Wood & Company 1933

This is a conversational series of lectures on sneezing It consists of six chapters covering the structure and function of the nose, the common cold, hay fever, other types of allergic sneezing, paroxysmal sneezing and chronic nasal catarrh Despite a wealth of valuable references the author pretends to be casual in the sense that he disdains to indulge in minute details, he employs literary by preference to scientific terms, he theorizes when it suits the purpose of clarity, and he speculates and defends his speculations Whole volumes on hay fever have been compressed into a brief chapter He speaks of "spluttering coughs," he says that "the common cold is not to be sneezed at" and he contributes as his last line "der is bore id sneezing dan was ever dreabed ob by der doze" The chapter on paroxysmal sneezing, the term he applies to the profuse sneezing and rhinorrhea of arising, is the screen on which he projects the McDonagh scheme of colloidal phases, brownian movement and molecular bombardment In the very preface he defends speculation on the ground that theorizing may explain many unanswered questions All this indicates that we are face to face with a self consciously seasoned observer at peace with his subject

The little volume is packed full of interesting data from statistics to prescriptions An Englishman would say that he betrays an awfully decent philosophy For instance, he mentions the summation of stimuli in hay fever, a phrase which epitomizes the necessity for complete testing in hay fever so that positive factors besides pollen may be eliminated during the hay fever season He sees a significance in the similarity between the common cold and hay fever, because chilling of the body in the former and injection of pollen into the leg in the latter both produce symptoms referable to the respiratory tract He even mentions the asthma aftermath of hay fever due to the continued irritation by factors such as feathers, physiologically inadequate by themselves to produce symptoms in the given case Aside from his explanation of early morning rhinitis, which Duke explains on a heat basis he touches on other types of physical allergy as sunlight and follows up by advocating physical therapy in the form of exercises, baths and, indeed, friction with a towel This clinician is aware of the marked lowering of the temperature of the nasal mucosa when the skin is slightly chilled, a fact to which a group of serious scientists have only recently deigned to bestow their attention The catholicity of his treatment methods, including specific pollen extract, nonspecific therapy, exercise, diet, local application cautery and electrotherapy, undoubtedly have won him a satisfied following The one track inoculating allergist will be amazed that there is so much more than a needle and syringe

Coke has written a tiny tract on sternutation It is a free hand blue print of the field done with nonchalant facility It will illuminate the subject if one will read the blue print with jovious effort matching the honest exuberance of its author

Surgical Nursing Arranged According to the Unit Method By Sister Mary Florence RSN RSN Instructor in Surgical Nursing Mercy School of Nursing Mercy Hospital Baltimore Maryland Paper Price \$1.75 Pp 119 Philadelphia & London W B Saunders Company 1933

This book is arranged according to the Morrison unit method of teaching It has five steps which include exploration of the student's background in the subject presentation or an overview of the unit assimilation or collection of information, organization with review and recitation to give evidence of necessary knowledge on the subject In order to cover the great variety of subjects in the limited time the book is divided into a number of general units containing illustrative specific surgical conditions There are eight units, which include pre-operative and postoperative management major abdominal operations glandular surgery including the breast, thyroid and lymph glands brain and nerve surgery, orthopedic surgery and various types of anesthesia with their management A few brief points are made as to the objectives and then a general discussion of the subjects in each unit is given, based

on recent textbooks. The nurse's point of view, given by the author, is especially pertinent and practical. A series of questions is then given regarding surgical subjects, hospital arrangements for the patient, and nursing problems, some going into scientific detail. References are included for the student who receives instruction in the wards as well as in the class room. The book does not include any information in reference to obstetric or purely medical conditions. Although the scope is limited to surgical nursing, the arrangement is well planned and is particularly suitable in conjunction with ward instruction.

Urologie infantile Par les Drs Beer et Hyman. Monographies de pediatrie et de puériculture. Preface du Dr Ed Papin chirurgien de l'Hôpital Saint Joseph. Traduit de l'Américain par le Dr Fritz Busser. Paper. Price 40 francs. Pp 262 with 50 illustrations. Paris: Gauthier Villars 1933.

This volume is beautifully made up. There are numerous illustrations, chiefly reproductions of roentgenograms, which are excellently chosen. The print, paper and illustrations leave nothing to be desired. It is the first book published in the French language devoted entirely to urology in infants and children and is a translation by Dr Busser of the American edition of 1930. The sequence of the arrangement of the subject matter is orderly and rational and is divided into fourteen chapters, each having appended a brief but valuable bibliography, chiefly from American and German sources. The first and second chapters take up general symptomatology and methods of examination. A chapter is devoted to a discussion of enuresis. An excellent chapter of forty-six pages is devoted to congenital malformations and one of twenty pages to chronic renal tuberculosis. The final chapter is devoted to malignant tumors of the kidney. This volume will supply an unfilled niche in the libraries of surgeons and students abroad.

A prova da fenolsulfoneftaleína e as relações ureicas (coeficientes ureo secretórios) na clínica geral. Por Machado Macedo, assistente título da 2ª clínica cirúrgica. Dissertação ao agregado do 7º grupo da Faculdade de medicina de Lisboa—1932. Paper. Pp 174. Lisbon: Livraria Ferri 1932-1933.

This book is devoted to the analysis of the accumulated experience of eighteen years in the second surgical clinic of the University of Lisbon (service of Professor Cabeça) in determining the functional capacity of the kidney in health and disease by means of phenolsulphonphthalein and by the various coefficients of urea secretion. The study embraces hundreds of cases and the analysis attempts to establish the relative merits of the various procedures and tests employed. After outlining the development of the field of tests of renal function historically, the author gives the technique for utilizing the phenolsulphonphthalein test. This consists of determining the amount excreted in the urine following its intravenous administration at thirty-five minutes and at sixty-five minutes. He emphasizes the fact that the amount excreted in the first period is often a better index of the renal functional capacity than the total excreted for sixty-five minutes, which however, he accepts for the standard of comparison with all the other tests used. In determining the coefficient of urea secretion he refers to the difference in opinion of various authorities as to the laws governing urea secretion. He calls attention to the work of Marshall and Davis, which he thinks refutes the assertion of Ambard that the secretion of the urea in the urine varies with the square root of its level in the blood. Marshall's work indicated that the urea secretion varies directly with the level of this substance in the blood and this idea is incorporated in the formula of Van Slyke. The author regards the formulas of both Ambard and Van Slyke as empirical and too theoretical and himself suggests three new formulas. The one however, which he prefers is Ur/\sqrt{D} in which Ur represents the level of the urea of the blood in milligrams per hundred cubic centimeters and D the urea excreted in the urine for twenty-four hours. However, in the actual performance of this test D is not actually determined but is calculated from data derived from the analysis of the two samples of urine collected. The most satisfactory method of ascertaining the functional capacity of the kidney according to Machado Macedo is to obtain at one and the same time both the phenolsulphonphthalein excretion and the coefficient of urea excretion by the formula of Ur/\sqrt{D} . This combination is effected by perform-

ing the tests in the morning with the stomach empty, the bladder is emptied, the phenolsulphonphthalein is injected, and at the same time blood is removed for the determination of the blood urea. The urine is then collected at the end of thirty-five minutes and sixty-five minutes. The phenolsulphonphthalein output is determined for each of the two periods and then for the hour as a whole. The urea is determined on a mixture of these two samples of urine and the amount for twenty-four hours calculated on the basis of the amount excreted in this hour. The coefficient of urea excreted is then determined according to the formula presented. Machado Macedo accepts the phenolsulphonphthalein test as the standard contrasting with it the results of all five formulas for coefficients of urea secretion. He finds that the new formula is most frequently in accord with the results of the phenolsulphonphthalein test. Therefore, he advocates its employment. The book gives evidence that the work has been done with meticulous care by men of broad understanding and great clinical experience. The conclusions represent the final results of prolonged intensive and controlled investigation.

Der elektrische Faktor der Nierenarbeit. Von Dr. h. c. Rudolf Keller. Paper. Price 1 mark. Jp 106 with illustrations. Mährisch Ostrau: Verlag Julius Klotz Nachfolger 1933.

This little volume is primarily derived from the author's book "Electricity in the Cell," with the addition of new material and some corrections. The aim of the author is to call attention to the part that can be played by electrical forces in the reabsorption of water and salts as well as for instance sugar and urea. It is shown that those parts of the renal tubule in which reabsorption of water takes place carry, by actual measurement, the greatest negative charge. The results are based mainly, on studies of invertebrates or lower vertebrates but not on mammalian kidneys. It is claimed that these parts have had the same function in the renal organization of all animals. It is shown that the migration in the electrical field could explain the reabsorption of electrolytes and nonelectrolytes, including water within those limits in which this reabsorption occurs. From the presentation it is evident that we are very far from a complete understanding of normal renal function, and that proof of the electrically governed transportation of substances has been possible, so far to only a limited extent. The neglect from which the lymphatic apparatus of the kidney has suffered is strongly emphasized. The little book is certainly stimulating.

New Feet for Old. A Simple Statement of Some Recent and Highly Cheering Discoveries Concerning Common Foot Disorders Their Cause and Cure for the Mutual Use of Physicians and Patients. By John Martin Bliss. B.Sc. D.O. M.D. With an Introduction by Edgecomb Pincheon. Cloth. Price \$2. Pp 140 with 43 illustrations. Garden City: Doubleday Doran & Company Inc 1933.

The author states that his purpose in writing this book is "that it may help to set cinderella free, and liberate men and women everywhere from a torment and a handicap wholly needless." The book contains a biography of the author, including the statement that he graduated in science, medicine and osteopathy. Many of his statements are based on guess work and not on accurate statistics. For example that three people out of five in the United States suffer from some form of foot trouble and that 30 per cent of these were under the stress of broken arches and bunions. Another misstatement is that more pain is inflicted on civilized people by foot troubles than all other physical ills rolled into one, that practically all of this is needless, and that nothing is needed for relief except a little knowledge intelligently applied. He states that 90 per cent of foot troubles are directly due to the use of shoes that broken arches and bunions can be corrected even in extreme cases by simple treatment and without the use of debilitating devices or hazardous operations. He makes the statement "few realize that in carrying the average person a mile the foot endures a stress of 250 tons." This book contains many "catch phrases" authority for which is not proved. The author's statement is untrue that there is very meager literature lay or medical on the foot, and practically none that exhibits a true grasp of its structure and problems. The author describes and illustrates his device known as the classifootometer the value of which seems to be overestimated. He states that

shoes forcibly mold the feet out of line. Ordinary daily activity, such as walking, running, or standing with the feet out of line, causes misplacement of bone, limitation of foot motion and strain of the arches. He speaks of 'unhappy feet'. He advises against the use of appliances, pads and supports which "are designed only to smother the symptoms without eradicating the cause". He states that the only obvious, sensible, line of treatment is to eliminate harmful shoes and to set the bones and reconstruct the arch. He states that broken arches are corrected by the re-setting of misplaced bones, and neither cure nor even relief is procurable by any other method and least of all by the wearing of freak shoes or arch supports. The author also says that most bunion-ridden feet can be corrected and made as straight as a Greek athlete by manipulation plus a simple operation, and without the removal of any normal bone structure whatever. He believes that a bunion is nothing more nor less than dislocation of the great toe joint and that it should be corrected but should never be operated on. Enough has been said to indicate the wholly unreliable and unscientific character of this opus.

Röntgendiagnostik der Knochen und Gelenkkrankheiten. Von Professor Dr. Robert Klenböck. Heft 2. Knochenkrankheiten. (Abteilung Knochenkrankheiten.) Paper. Price 7.60 marks. Pp. 105. 192 with 19 illustrations. Berlin & Vienna. Urban & Schwarzenberg. 1933.

This monograph, by one of the greatest European roentgenologists, is on the subject of *echinococcus* disease of the bone. The illustrations are of the highest character from the standpoint of pathology and for teaching purposes. The book will be of interest to the roentgenologist and to the specialist in bone pathology. It will be of little interest to the general practitioner.

Undulant Fever and Its Relation to Brucellasis in Cattle and Swine in Virginia. By Leland Edson Starr, Assistant Animal Pathologist. A Dissertation Submitted to the Graduate Faculty in Candidacy for the Degree of Doctor of Philosophy. University of Virginia. Doctoral Thesis No. D 203. Virginia Polytechnic Institute. Virginia Agricultural Experiment Station. Technical Bulletin 48. Paper. Pp. 50. Blacksburg. Montgomery County, Virginia. 1933.

This carefully conceived monograph deals primarily with the distribution of brucellasis (Bang's disease, contagious abortion) in domesticated animals in the state of Virginia. During the years 1931 and 1932, 45,285 dairy cattle were tested for *Alcaligenes* (*Brucella*) agglutinins, this constitutes approximately 10 per cent of the dairy cattle in Virginia. The serums of 10 per cent of the tested cattle gave positive reactions. While the disease is widely distributed throughout the state the percentage of infection is greatest in the intensive dairy sections. The serums from cattle in seventeen dairy herds consisting of 362 animals which had supplied raw dairy products to individuals who subsequently developed undulant fever gave positive reactions in 47.2 per cent of tests. This demonstrates the close relationship of the infection in dairy cattle to the occurrence of its homologue undulant fever, in man. The percentage of positively reacting serums was much greater among those employed in abattoirs and among veterinarians than in the general population. Seventy proved cases of undulant fever have occurred sporadically over the state during the period from 1929 to 1933. The greatest number of these cases occurred in the northern part of the state which corresponds with the area in which *Alcaligenes* infection is most prevalent among dairy cattle and where comparatively little of the milk is pasteurized. About 40 per cent of the cases of undulant fever appeared to be the result of contact with infected animals or their discharges while 60 per cent apparently resulted from the ingestion of raw contaminated dairy products. The goat population in Virginia is small and these animals did not appear to be a factor in any of the cases of undulant fever investigated by the author. Of 1,316 samples of swine serums 3 per cent gave positive reactions. There is little evidence that the occurrence of brucellasis in swine is of any great importance from the standpoint either of the live stock industry or of the public health. Irradiation of *Alcaligenes* infection in dairy herds should be insisted on by dairymen, veterinarians, public health officers and physicians. It seriously lowers milk production in dairy herds. By cooperating with veterinarians and physicians in their efforts to remove a public health hazard the dairyman is also conserving his economic interests.

Medicolegal

Malpractice Death Following Cesarean Section, Failure to Discover Fibroid Tumor.—The defendant-physician was employed to attend the plaintiff's wife during pregnancy and childbirth. He examined her from time to time and found her condition satisfactory. He attended when labor came on, and after he found himself unable to effect delivery by manipulation he used forceps, but without success. He then called in a consultant, an obstetrician of many years experience, and a cesarean section was performed. In the course of the operation a previously undiscovered fibroid tumor was found in the posterior wall of the uterus. The patient died some sixty hours after she had been operated on. The husband sued the attending physician, charging negligence and unskillfulness. The trial court gave judgment in favor of the physician, and the husband appealed to the court of appeals, first district, division No. 1, California.

No evidence was offered by the plaintiff, said the district court of appeals to show negligence or unskillfulness on the part of the attending physician in connection with his failure to discover the fibroid tumor prior to the operation or to show that by the exercise of ordinary care it could have been discovered and when due care, skill and judgment are exercised a failure to make a correct diagnosis does not render a physician liable. The plaintiff did not claim that the cesarean section was negligently or unskillfully performed but relied solely on the contention that it should not have been performed. On the plaintiff's behalf, a physician testified that the tumor would not have prevented the normal delivery of the child, that a cesarean section was not necessary and should not have been performed, and that if there were obstructions that prevented delivery a symphysectomy should have been done. On behalf of the defendant, however, one physician testified that the tumor would have prevented the natural birth of the child and three expert obstetricians testified that symphysectomy in cases of childbirth was obsolete, that it was highly dangerous and was liable to leave the patient a cripple, that cesarean section was universally used when a baby could not be delivered through the natural channel, and that the course pursued by the defendant physician was in accordance with good obstetric practice.

The judgment of the trial court for the defendant-physician was affirmed.—*Benn & Abions (Calif.)*, 19 P. (2d) 523.

Evidence Testimony of Expert Witness as to Mental Capacity of Grantor.—One Hays, 80 years old, conveyed certain property to the appellant Harrison. Hays died a few months later and his collateral heirs instituted proceedings to set aside the conveyance. From a judgment for the collateral heirs, Harrison appealed to the court of civil appeals of Texas, San Antonio. He urged error among other things in the action of the trial court in permitting a physician to testify that in his opinion Hays did not have the mental capacity to convey the property in controversy. This was error said the court of civil appeals. It is well settled in Texas that no witness whether he be a subscribing witness, a medical expert or a layman, can state over proper objection, his opinion of the capacity of the testator or the maker of any contract to make such instrument when such opinion assumes the shape and has the effect of being an opinion on the legal capacity of the party in question. It is therefore obvious that the testimony here complained of was inadmissible over timely and appropriate objections. The judgment was reversed and the cause remanded.—*Harrison vs. Davis (Texas)* 58 S. H. (2d) 102.

Evidence Lay Testimony as to Sickness.—Where two people said the Supreme Court of Arkansas came in contact with each other frequently it is not a matter of expert knowledge for one to tell whether the other appears to be sick or well. These are matters of common experience and observation and a lay witness after stating the facts on which his opinion is based, may give his opinion in such matters. It is proper, therefore for a mother to testify that her children after being exposed to mumps tumors were pale and sick.—*Southern Ice & Utilities Co. v. Bryan (Ark.)* 28 S. H. (2d) 920.

CENTRAL SOCIETY FOR CLINICAL RESEARCH

Sixth Annual Meeting held in Chicago Oct 27 and 28 1933

The President DR M A BLANKENHORN, Cleveland, in the Chair

(Continued from page 1994)

A Study of the Effect of Mercurial Diuretics on Kidney Disease

DRS E S MAXWELL JOHN W SCOTT and JOHN HARVEY, Lexington, Ky We have had the opportunity of observing the clinical course and of studying the kidneys post mortem in twenty-one patients to whom mercurial diuretics had been given and who died of congestive cardiac failure One patient had had 240 cc of salyrgan in 198 doses Our examination of the literature leads us to believe that this is the largest amount given to a patient who has come to autopsy Six patients had salyrgan within seventy-two hours of death Three patients showed calcium deposits in the kidney tubules The kidneys from other patients dying of congestive cardiac failure, who had not had mercury, were also examined Our observations seem to us to indicate that 1 Changes in the kidneys from patients who have had mercurial diuretics are in no way different from those commonly seen in patients dying of congestive cardiac failure without the use of mercury 2 Continued use of salyrgan in doses of 12 cc or less, has not, in our experience, been followed by permanent kidney damage, and in one instance no damage could be demonstrated after 240 cc of this drug in such doses had been given 3 A dose approximating 12 cc (the contents of one ampule) need rarely be exceeded for effective diuresis

DISCUSSION

DR B T HORTON, Rochester, Minn I think that these observations on the use of mercurial diuretics confirm the general clinical impression regarding these drugs At the Mayo Clinic we have observed fewer toxic manifestations following the use of salyrgan (mersalyl) than of novasurol (merbaphen), and I think there can be no doubt that salyrgan is a safer diuretic drug to use than novasurol This has been recently demonstrated by a study carried out by Binger and Keith Toxic manifestations that have been observed, usually followed the use of novasurol, consisted of stomatitis, gross hematuria and diarrhea At necropsy we have seen in a few instances ulcers in the bowel, particularly in the colon, following the use of these mercurial compounds It is obvious that an ideal diuretic drug has not yet been found

DR MOSES BARRON, Minneapolis I should like to ask whether the authors saw any changes in the urinary excretion, as to the amount of albumin and casts, following long repeated doses of salyrgan

DR JOHN FOULGER, Cincinnati There is a third mercurial drug used as a diuretic, called novurit It is better than either salyrgan or novasurol In one case of extreme edema the patient began to show diuresis in twenty minutes after the injection of 2 cc of Novurit intravenously That patient was absolutely refractory to either of the other two drugs With regard to novasurol, there arises a question as to whether the barbitol present would affect toxicity

DR ROGER MORRIS, Cincinnati Some years ago I had a patient who had what is called clinically parenchymatous nephritis, with extreme edema The skin of the legs was so tense that it cracked and fluid was oozing from it. She had been alkalinized with no benefit We were able to change the

reaction of the urine and then gave her salyrgan in capsules. They were put up in that form for a time for experimental use I have never seen such marked diuresis following the administration of salyrgan by mouth The edema cleared up The amount of albumin in the urine, which was so great that it almost coagulated solid in a tube, decreased and the patient made a good recovery At no time was there blood in the urine She died a year later from carcinoma of the breast Certainly her kidneys were not damaged by the administration of salyrgan so far as one could observe clinically There was nothing in the urine to indicate renal irritation She made a good symptomatic recovery

DR WILLIAM THAMMER, Chicago Dr Brams, at Michael Reese Hospital, administered novurit intravenously to a number of patients and found that its diuretic action was at least equal to that of salyrgan

DR J W SCOTT Lexington Ky I want to reply to Dr Barron because I know more of the clinical course of the cases than Dr Maxwell The case he refers to in which the diuretic has been used for a long period the patient that had 240 cc over a course of five years was not under our observation in the hospital until the last few days of her life No observations were made on the effect of salyrgan on the amount of albumin and casts in the urine

Extrapelvic Symptoms Associated with Ovarian Cystic Disease

DR E L SEARINGHAUS, Madison, Wis Frequent occurrence of an involutional group of symptoms in women with demonstrable cystic disease of the ovary led to a study of sixty-three case histories Some patients were treated as premature cases of menopause until pelvic examination or curettage showed that the pathologic process was one of ovarian cysts with the commonly associated hyperplastic endometrium The observations in these two groups indicate that complaints usually thought of as due to vasomotor, cardiovascular or psychoneurotic disturbances may be caused by endocrinopathies In thirty-six of the sixty-three women there were palpably enlarged ovaries Curettage, done in only thirty cases, demonstrated endometrial hyperplasia The menstrual histories were characterized by menorrhagia, metrorrhagia, irregular intervals, frequent flowing, and some long periods of amenorrhea Most of the patients were in the third and fourth decades The extrapelvic symptoms found so frequently in this group are the same as those seen in the climacteric Obesity and various abdominal pains occurred in 71 per cent Nervousness was a complaint in 71 per cent, with attacks of melancholy and frequent weeping in 60 per cent Hot flashes appeared in 57 per cent, with dyspnea and palpitation without cardiac cause in 56 per cent Vertigo was bothersome in 49 per cent Morbid worrying was recognized in 40 per cent insomnia in 35 per cent, and pares thesias in 24 per cent The nature of these symptoms and the entire clinical picture would lead to a diagnosis of involutional psychosis except for the age and pelvic condition It is suggested that the psychic, vasomotor and physical changes are essentially the same as in the climacteric because of similar disturbance to the equilibrium between the anterior pituitary, the ovaries, and such other organs as the suprarenals Quite apart from the experimental therapy to be described or the hypothesis of endocrine origin suggested, this group of complaints merits attention Instead of a diagnosis of psychoneurosis following such a history, a detailed inquiry about the menses and gynecologic examination are warranted There is reason to believe that the cystic ovary is a result of abnormal type of pituitary stimulation to the follicle The cystic ovary produces the same effect on the uterus that follows continued administration of large doses of theelin in the absence of the functional corpus luteum Therefore therapy has been planned with use of materials to stimulate luteinization of the cystic follicles First a potent fraction was prepared from pregnancy urine concentrates and used in twenty of these cases Later genuine anterior pituitary extracts of assayed potency were employed with thirty-one of the women A number had both types of treatment The material is given intravenously, in doses equivalent to 0.5 Gm of dried anterior pituitary, administered once each month The time selected is fourteen days after the menses begin, when ovulation should normally occur

Results of considerable promise were secured, including regulation of menstrual rhythm and volume and relief of the symptoms described

DISCUSSION

DR W J DIECKMANN, Chicago Hyperplasia of the endometrium is a very common pathologic diagnosis made on curettings. The curettage is usually performed for abnormal uterine bleeding. In a large number of patients, the pelvic examination indicates an essentially normal pelvis. I believe that the hyperplasia is due to hormonal stimuli and the bleeding in a few cases has been stopped by the injection of serum from pregnant women and also by anterior pituitary. Novak states that the cessation of the bleeding after the injection occurs too quickly for any hormone action to have occurred. My treatment has been empirical. I wish to ask whether or not any curetting was done after the patients were clinically cured.

DR GEORGE B EUSTERMAN, Rochester, Minn. The gastrointestinal disturbances in these women are of great interest. Many will recall the era when removal of the ovaries for disturbances real or imaginary, was a popular procedure with some surgeons. Many of these victims were young women, and the premature menopause was eventually followed by gastrointestinal disturbances, usually of a spastic nature; these spastic phenomena invariably involving the pylorus and colon. Of course, some of these individuals were psychoneurotic from the outset, a fact that might have been responsible for their disturbances as well as for the operation, but many of them had a stable nervous system and the subsequent gastrointestinal disturbances could only be related to the operation. Of course in a goodly number of these patients nervous instability in one form or another also supervened.

DR WALTER W HAMBURGER, Chicago I should like to ask Dr Sevringhaus whether he believes that some of these patients are really psychotic.

DR E L SEVRINGHAUS, Madison, Wis. I am confident that cure or even relief has not been accomplished by curettage, because the symptoms have continued in spite of thorough curettage. I have been unable to recure after treatment. I do not say that luteinization has been produced. Curettage and pelvic examinations have not relieved these patients. Also, relief from this pituitary extract given once per month is not permanent. Omission of monthly treatments was followed by return of symptoms usually within two months. There were some unpleasant, rather temporary, reactions simulating the reaction from intravenous injections of histamine, which consist of a bad taste, feeling of extreme warmth, vertigo, and nausea with no emesis, lasting from three to five minutes and coming on a minute after injections. This reaction may continue even though the material has lost its potency judged clinically or by assay in rats. In response to Dr Eusterman's comments, I think it must be realized that with the climacteric there is disturbance of the particular organ or mechanism in the body that is the most labile. There are certain types of women who will show vasomotor disturbance which is common a small portion with a pseudothyrotic picture, and then there is the very large fraction who have the psychotic picture. I am sure that the gastro-intestinal disturbances are due to functional change in the part of the body that is most labile. In response to Dr Hamburger's question I think that these patients develop definite psychoses, if one calls a woman psychotic because she worries so as to make of herself a nuisance to her family, if she is so unstable, suffering with dyspepsia and palpitation, that she cannot take care of her simple household duties, and if she is demanding attention from her husband at every turn. Some women have been sent to the hospital for neuropsychiatric care because of these symptoms. The curious thing is the frequency with which psychotic or semipsychotic pictures are seen associated with organic lesions of this type.

Parathyroid Hypertrophy and Hyperplasia of Rickets and Osteomalacia

DR R M WILDER, G M HIGGINS and C. SHEARD, Rochester, Minn. Experiments with chicks reveal that deprivation of vitamin D insufficient in degree to cause rickets will produce hypertrophy and hyperplasia of the parathyroid glands and that the parenteral administration of parathyroid extract in such minor degrees of deprivation of vitamin D prevents

this hypertrophy and hyperplasia but that when the deprivation of vitamin D is extreme, so that rickets is clearly in evidence, the administration of parathyroid extract may restrict but will not prevent the hypertrophy and hyperplasia of the glands. It appears from this and from other evidence that the hypertrophy and hyperplasia of the parathyroid glands of chicks, under conditions of deficiency of vitamin D, depend on their accelerated functional activity. Other observations are interpreted to mean that the supply of parathyroid hormone determines the sensitivity of the organism to the action of vitamin D. A diminished supply of the hormone as after parathyroidectomy diminishes the ability of the organism to function normally with restricted amounts of vitamin D; an augmented supply conditions the tissues of the organism so that the effects of the vitamin are more intense and so that amounts of the vitamin that otherwise would not prevent rickets do prevent rickets. By virtue of the capacity of the parathyroid glands to accelerate the rate of supply of their product, and owing to the resulting conditioning of the tissue (increased sensitivity to vitamin D), the organism is enabled to withstand periods of relative deficiency of vitamin D which otherwise would produce rickets or osteomalacia. This compensatory mechanism is adequate to protect against relative degrees of deficiency of vitamin D, it is inadequate, as would be expected, when deficiency of vitamin D is extreme.

DISCUSSION

DR JOSEPH F BORG, St. Paul I should like to ask the authors whether in their cases of marked vitamin D deficiency with parathyroid treatment they found any changes in the blood calcium.

DR RUSSELL M WILDER, Rochester, Minn. In the experiment with only slight deficiency of vitamin D, the blood calciums were not depressed yet the parathyroid glands enlarged. This seems to point to the direct stimulation of the parathyroids in vitamin D deficiency rather than to stimulation by the hypocalcemia that accompanies conditions of more severe vitamin D deficiency.

The Association of Pellagra and Vincent's Infection

DRS TOM D SPIES and HENRY A DEWOLF, Cleveland Six typical cases of pellagra, with stomatitis and glossitis, were selected for study. Repeated smears of the mouth and, in two instances of the vagina showed a conspicuous number of spirochetes and fusiform bacilli as well as a predominance of these two organisms. The patients were then placed on a restricted diet of water and 500 Gm or more of autoclaved yeast; their lesions promptly remitted and subsequent smears from the same areas in the mouth and vagina showed a great decrease in the number of spirochetes and fusiform bacilli. The clinical significance of these observations is shown to be important in that two patients, confined to a hospital for contagious diseases while being treated for severe Vincent's infection were found by a consultant to have extensive lesions of pellagra.

DISCUSSION

DR JOSEPH L MILLER, Chicago Dr H Gideon Wells has been doing some work on the etiology of ulcers in the buccal cavity. He believes that fusiform and spirillum bacilli are always secondary invaders. They are not responsible for the lesion but find here a suitable place for their development.

Studies on Etiology and Treatment of Neutropenic States

DR CHARLES A DOAN, Columbus, Ohio The importance of differentiating the many clinical conditions in which leukopenia appears as a prominent part of the laboratory examination is evident. More than 80 per cent of the patients referred to our group with leukopenia during the past three years have not been of the types that fall into one of the several subdivisions of the original Schultz syndrome. An uncritical attempt to treat all leukopenias by any one method will continue to result in a large proportion of failures. An understanding of the underlying mechanism in the individual case is the first essential to rational therapy. This may best be secured by a careful study of the quality and character of the blood cell present interpreted in the light of a careful history and physical examination.

A special study during the past year of the blood of patients in whom a severe infection definitely preceded the development of leukopenia resulted in the isolation of several organisms: Friedlander's bacillus, *Streptococcus haemolyticus*, *Streptococcus viridans* (two strains) and *Staphylococcus aureus*. With the first two we were able to reproduce the peripheral blood and bone marrow pictures observed in the respective patients from whom these strains were isolated. Intraperitoneal and intramuscular implantations of living cultures in celloidin or gelatin capsules and intravenous inoculation of cultures and sterile filtrates were made. I conclude that it is not so much the type of organism as the state of reactivity of the host which conditions the level of leukocytic response under these conditions and that exsanguination-transfusions present the best hope from a therapeutic standpoint.

In certain cases of chronic, noninfectious deficiency neutropenia with a concomitant moderate degree of secondary anemia and thrombopenia, intravenous liver extract has controlled the levels of all three bone marrow elements.

The effect of varying small doses of x-rays on myelopoiesis in pigeons has been studied in the attempt to determine the stimulatory versus the destructive effects of this suggested method for treating neutropenia. I have yet to find a stimulatory dose which does not show some prior evidence of myelocytic destruction. I therefore believe that roentgen treatment is contraindicated whenever a hypoplastic myeloid marrow underlies a given leukopenic state. In this type of case some nucleic acid or nucleotide derivative continues to offer the best promise of successful myelopoietic stimulation.

Primary Granulocytopenia After Administration of Benzene Chain Derivatives

DRS F W MADISON and T L SQUIER, Milwaukee. The increased incidence of primary granulocytopenia (agranulocytic angina) has paralleled the increase in use of drugs containing a barbiturate combined with amidopyrine. Analysis of a series of thirteen consecutive cases has shown that all the patients had taken, over varying periods of time prior to the onset of their acute symptoms, one or more drugs containing benzene ring derivatives. All of these cases occurred either in physicians, nurses or patients under a physician's care prior to the onset of the granulocytopenia. Seven patients were under close medical observation and were known to have had normal white cell response during the illness that preceded the granulocytopenia, and after recovery developed granulocytopenia during the period of convalescence. All of them had been given drugs containing the benzene ring. In five of the cases, benzene ring derivatives were used during the treatment of the granulocytopenia and four patients died (mortality, 80 per cent) while the one patient living has a chronic granulocytopenia. In eight of the cases benzene ring derivatives were absolutely avoided and only two patients died (mortality 25 per cent), one within thirty-six hours, and the other failed to show any evidence of response to treatment. One patient who had made an excellent recovery from acute granulocytopenia showed marked fluctuations in the granulocyte count and was found to have been taking a benzene ring derivative. When this was stopped, the count promptly stabilized at a normal level. Two patients after recovery showed an abrupt drop in the granulocyte count after a single isolated dose of a benzene ring derivative. All who recovered and have avoided the use of these drugs are living after periods of from three months to two years.

Eleven rabbits were given allyl-iso-propyl barbituric acid (allonal) with amidopyrine by mouth in relatively large doses. One rabbit showed an abrupt drop in the granulocyte count on the twenty-sixth day of medication and died on the thirtieth day. Preceding death there was complete absence of granulocytes in the peripheral blood and the picture was characteristic of primary granulocytopenia. On necropsy there were no grossly abnormal observations, except that on the tongue there were a number of small whitish blebs and a small pit on the left side of the tongue as from an ulcer. The bone marrow was absolutely lacking in cells of the granular series. None of the other rabbits showed the blood picture of granulocytopenia, but three were found to have definitely hypoplastic bone marrow on necropsy and in these marked diminution of eosinophil granules was a striking feature.

DISCUSSION ON DEFICIENCY OF BLOOD CELLS

DR C H WATKINS, Rochester, Minn. In a large percentage of our cases of agranulocytosis, there seems to be a possibility of an idiosyncrasy to amidopyrine or to one of the derivatives of barbituric acid. A great deal of clinical and experimental work will be necessary to settle this question, but it seems reasonable to assume that a leukopenic syndrome may represent the outward manifestation of an idiosyncrasy to a drug of this class. I have one patient who has had a total of twelve attacks of agranulocytosis at intervals of every one or two months for the past two and a half years. This patient had been taking amidopyrine for migraine. Since she has discontinued the use of this drug and of all other sedatives, she has had no further attacks. One other patient seems to be able to produce leukopenia at will by taking 10 grains (0.65 Gm) of amidopyrine. If agranulocytosis sometimes is the result of idiosyncrasy to drugs, I think it must also be assumed that there is a primary dysfunction of the bone marrow, so far as reduction of leukocytes is concerned for there is no change in the blood of most persons following the use of amidopyrine or of any of the derivatives of barbituric acid.

DR C W BALDRIDGE, Iowa City. I should like to ask Drs Madison and Squier whether they think that the action of these drugs is the same as that of benzene, because years ago when benzene was given in leukemia the action was not nearly so rapid as the reactions they have described.

DR SAMUEL B GRANT, St Louis. I have had an experience with one patient that confirms these studies of Drs Madison and Squier. A patient with arthritis who had taken amidopyrine regularly for several months discontinued the drug on admission to the hospital for cholecystectomy. During convalescence from the operation she was given a dose of a sedative combined with amidopyrine. A few hours later she had a chill followed by transient unexplained fever. Blood counts were not made. A few weeks later she started taking amidopyrine and immediately had another chill and rapid rise of temperature. It happened that blood counts four days previously had been normal. On the following morning the leukocyte count was 2,000, with 2 per cent granulocytes. I had the feeling that the amidopyrine had something to do with it and she was never allowed to take it again.

DR P S HENCH, Rochester, Minn. A patient of mine with chronic infectious arthritis developed on September 12 a mild fever (99-99.5 F) but no chill. The white blood count, which had recently been 8,600, was found to be 2,100. In the next three days it dropped to 1,400, the differential count showed 49 per cent lymphocytes and 9 per cent neutrophils. Dr Watkins suggested that the neutropenia might be due to allonal or amidopyrine, which the patient had been given in small doses for six days. All drugs were stopped and on September 17 the white blood cells had returned to 6,000, with a normal differential count. The patient felt quite well throughout the episode. September 23, he developed a jaundice with a serum bilirubin of 12.5 mg direct reaction. The jaundice lasted one week and was not associated with a change in red count or hemoglobin. Have Drs Madison and Squier noted jaundice in any of their cases?

DR JOHNSON MCGUIRE, Cincinnati. I should like to add one case to those reported by Drs Madison and Squier. The patient was an elderly woman who developed a primary leukocytopenia. Before the development of symptoms she had been taking occasional doses of allonal and amidopyrine. The white count dropped to 1,000 and the granulocytes disappeared. Pneumonia, perirectal necrosis and myocardial insufficiency appeared consecutively. There was an increase in the white blood cells to 6,000, with 80 per cent neutrophils, the day before death.

DR JOHN FOULGER, Cincinnati. I should like to ask whether Drs Madison and Squier consider that barbitals with or without phenol or amidopyrine is a causative factor. In their animal experiments they used what is really pure allonal. In the treatment of patients one usually gives allonal plus amidopyrine. Do they think the action is due to the phenol group or some times to the barbituric acid group or to the synergistic action of the two?

DR RICHARD M. MCKEAN, Detroit: I should like to ask whether the patch test for cutaneous sensitization or for intracutaneous injection with the benzene chain group was used in any of these cases as evidence of a true allergic phenomenon.

DR CARROLL L. BIRCH, Chicago: Was an attempt made to determine whether there was a redistribution of these cells or a definite regeneration? This constant drop may be due to redistribution of the white cells rather than to a destruction.

DR F. W. MADISON, Milwaukee: In answer to Dr Baldrige's question, whether we think the action is the same as the action of benzene I would say no. We started out with the feeling that perhaps it was an action similar to that of benzene. We abandoned that very soon. The fact that we see these acute drops not only experimentally but clinically rules out the toxic effect that has previously been described. Whether there is any relation between the two types we do not know. We have a definite feeling that we may be dealing with a peculiar type of allergic response, the nature of which we do not know and have not been able to determine. In answer to the question about the chemistry, I would say that the allonal we used in experimental rabbits is the same as is used clinically. Whether the barbituric acid derivatives without amidopyrine are capable of causing this type of reaction, we do not know. We have wondered about it but we have no definite evidence except that recently we gave a patient amytal alone and had no response in the total white count. That there may be a synergistic action is entirely possible. In answer to Dr McKean, we have not done the patch tests. We rather doubt that we shall get any evidence of skin sensitivity.

Mechanism of the Production of Anemia

DR RAPHAEL ISAACS, Ann Arbor, Mich.: A study of the sternal bone marrow of seventy-five patients with various types of anemia was made, serum suspensions of the marrow being used for accurate counts of the number of cells per cubic millimeter and for differential counts. Seven stages in the development of the erythrocyte can be identified in the bone marrow: a primitive blast (lymphoid cells), the megaloblast, the macro-normoblast, the normoblast, the reticulocyte, the granule red blood cell and the mature erythrocyte. The primitive cells are increased in number in chronic nephritis and pernicious anemia but are decreased in the anemia of acute hemorrhage, in aplastic anemia and in Hodgkin's disease treated with x-rays. In the two latter conditions and in chronic nephritis there is an arrest of development at this stage but in pernicious anemia (untreated) the inhibition develops at the megaloblast stage. Megaloblasts are reduced in number in the other diseases enumerated. The macro-normoblast is the predominant stage after acute hemorrhage, but the actual numbers are also increased in pernicious anemia in beginning remission. The normoblastic stage is the predominant form in normal bone marrow and these cells are decreased in number in all anemias. The macro-normoblastic growth in acute hemorrhage is not the result of inhibition of growth (failure to shift to the right), but a so-called shift to the left because of inability of the cells to ripen fast enough to meet the demands of the peripheral circulation. The megaloblast stage is sensitive to the effects of liver or stomach medication; the macro-normoblast is stimulated by iron; no known therapeutic agency affects the maturation of the primitive blast.

DISCUSSION

DR C. W. BALDRIDGE, Iowa City: I should like to ask Dr Isaacs whether he thinks that iron actually stimulates blood formation or merely furnishes a substance that is necessary for normal hemopoiesis, also whether or not iron will work satisfactorily in the anemia of chronic nephritis as it will in the anemia of hemorrhage.

DR ROGER MORRIS, Cincinnati: After the cells have responded to liver therapy will they return to the macro-normoblast stage? If the macro-normoblasts predominate after the response to liver treatment have you tried carrying the patient along with iron to see whether the improvement will continue?

DR RAPHAEL ISAACS, Ann Arbor, Mich.: In answer to Dr Baldrige I believe that the iron stimulates the formation of normoblasts as the blood remains stationary until iron is

given. In chronic nephritis, iron alone will not stimulate the cells to grow. In reply to Dr Morris: If the bone marrow cells respond to liver they quickly return to normal. The first stage is a decreased number of megaloblasts and then the bone marrow becomes absolutely normal as far as I can tell. The plan of carrying the patient along with iron after the megaloblasts have responded to liver treatment presents some complications. Patients with pernicious anemia have stored in their bodies enough iron to carry them through, so that it is doubtful whether additional iron will have any marked effect.

The Failing Heart in Acute Infections

DR LOUIS M. WARFIELD, Milwaukee: The generally accepted view that the heart fails in acute infections is probably incorrect. So-called heart failure is actually peripheral collapse. The customary methods employed to stimulate the heart should be abandoned and measures used to combat the peripheral collapse.

DISCUSSION

DR J. W. SCOTT, Lexington, Ky.: I should like to ask Dr Warfield if he has had any experience with carbon dioxide by inhalation in the treatment of peripheral collapse. The triad of circulation volume, depth of respiration and general tonus, the latter actuating the venopressor mechanism, is of chief importance in the consideration of peripheral collapse. It is a remarkable fact that each one of the components of this triad is stimulated by the inhalation of carbon dioxide.

DR WARREN B. COOKSEY, Detroit: I should like to ask Dr Warfield whether he has tried concentrated solution of dextrose intravenously in this condition, or whether he would care to make any comment on its use in these patients.

DR MOSES BARON, Minneapolis: I should like to ask Dr Warfield how he would explain the apparent myocardial weakness following many acute infections. After influenzal and streptococcal infections I often find a definitely low cardiac reserve, as evidenced by dyspnea on slight exertion plus a rapid pulse. This must be due to a myocardial weakness. It is undoubtedly true that the greatest part of the cardiovascular effect is from peripheral collapse but there is also present a temporary change in the myocardium.

DR MORRIS H. NATHANSON, Minneapolis: Although it is true that the heart is usually not functionally impaired in infections, there is one infectious disease in which there is evidence that the myocardium is seriously damaged and in which the myocardial changes undoubtedly play the chief part in the outcome. This is diphtheria. Several years ago I carried out an electrocardiographic study of patients suffering from diphtheria and found marked changes. In certain cases these changes extend into convalescence and the only patients showing circulatory collapse were those who had the abnormal electrocardiograms. These electrocardiographic changes would return to normal after four to six weeks. I was also able to reproduce these abnormal electrocardiograms in cats by the injection of diphtheria toxin. I also carried out a study with the electrocardiograph in other infectious diseases and found that as compared with diphtheria, high grade electrocardiographic changes are relatively rare even when the patient shows signs of severe circulatory failure. These observations support the concept that the peripheral mechanism is most frequently the basis for the circulatory failure in most infectious diseases.

DR L. M. WARFIELD, Milwaukee: In answer to Dr Scott I have never tried carbon dioxide because I have always felt that what the heart needed was oxygen. I have used oxygen in cases of surgical collapse following operation. I have seen one patient, a young woman to whom 12 liters of fluid was given in twenty-four hours by means of the jejunal tube, the rectum and intravenous injection. She came out of the apparent death collapse and is well. That I have attributed to the enormous amount of fluid plus the oxygen. In reply to Dr Nathanson I specifically stated that diphtheria was one of the diseases that cause myocardial failure. His discussion is interesting. I think diphtheria, septic emboli and possibly rheumatic fever are the diseases more prone to cause myocardial failure. As to concentrated dextrose I have given it. The only objection to giving it as well as saline solution is that they leave the blood vessels rapidly. The difficulty has been that too little

saline solution has been given, the amount being 1,000 cc when it should have been 4,000. With regard to the question that after influenzal infections the myocardium is left in a very labile state, I think that one has to admit that I do not think that this is any argument against the fact that when these people die of so-called cardiac failure they die of peripheral collapse rather than of cardiac failure on the part of the myocardium, though the myocardium may be actually diseased. If the heart is beating too rapidly, the recovery period is so short that there is decreased circulation in the heart and anoxemia occurs. I do not know what one could do if one could stimulate the heart or what good it would do; the patient's condition is hopeless.

Clinical Experience with an Antitularens Serum

DR. LEE FOSHAY, Cincinnati. During the past two years, seventy patients with tularemia have been treated with an antitularens goat serum. The serum appears to possess therapeutic value as judged by the clinical responses obtained. A quantitative analysis of data from the treated group compared with those from 121 control patients confirms the clinical impression that significant changes in the course of the disease are due to the serum therapy. The mean duration of disease has been reduced by almost one half and the duration of adenitis has been diminished by more than one third.

Heart Movie The Electrocardiographic Registration of the Normal Heart Beat

DR. CLAYTON J. LUNDY, Chicago. This animated motion picture starts with a review of the anatomy of the heart and its conduction system. There follows the showing of the origin of the stimulating impulse in the sinus node and its spread over the entire heart simultaneously with the formation of the electrocardiogram. It includes the showing of auricular and ventricular systole and diastole correlated with the electrocardiogram, intra-auricular and intraventricular pressure, and the electrically reproduced heart sounds, together with the action of the aortic, mitral and tricuspid valves.

The Etiology of Felty's and Related Syndromes

DR. HARRY A. SINGER, Chicago. In 1924, Felty described the occurrences in five adult patients of a syndrome characterized by chronic deforming arthritis, splenomegaly, lymphadenophy, leukopenia and cutaneous pigmentation. None of the five patients were followed to autopsy. Felty offered two explanations for this unusual clinical syndrome: (1) that the manifestations are part of one pathologic process, (2) that the syndrome is merely a confusion of two separate clinical entities, i.e., arthritis and Banti's disease, occurring coincidentally in the same individual. Felty favored the first explanation chiefly on the basis of the law of probability. In 1932, Hanrahan and Miller recorded a case of Felty's syndrome in which splenectomy was followed by "markedly beneficial effects." The question of the nature of the underlying disease process was left *sub judice*. I have studied two adult patients in whom the clinical picture was that of Felty's syndrome. In both instances, cultures during life from the blood stream yielded *Streptococcus viridans*. Both patients died and at autopsy presented the typical bacteriologic and anatomic evidence of sepsis lenta. The evidence obtained in these two cases serves to account for the Felty syndrome, Chauffard-Still's syndrome and Still's disease on one common pathogenic basis. Furthermore, the evidence indicates that at least a certain number of so-called primary splenic anemias of the Banti type really represent instances of sepsis lenta.

DISCUSSION

DR. P. S. HENCH, Rochester, Minn. Chauffard in 1896 and Herringham in 1909 called attention to the association of arthritis in adults with splenomegaly and hepatomegaly. Anemia was not emphasized. In 1897, Still noted arthritis in children with anemia, enlarged lymph glands and enlarged spleen but didn't mention hepatomegaly. Others have since reported cases of arthritis variously presenting a reticulo-endothelial response, with leukopenia or leukocytosis. Felty's syndrome concerns itself with a chronic arthritis, anemia, enlarged glands and enlarged spleen, but the liver is not mentioned. While it is well to point out such variations, it seems unwarranted to give each combination a new name. As chronic infectious (atrophic) arthritis progresses anemia is expected

and a moderate glandular enlargement may be viewed without concern. If the glands are immoderately enlarged, biopsy may reveal, however, an associated tuberculosis, Hodgkin's disease or even cancer. One should not expect to find splenomegaly in arthritis oftener than in 1 per cent of the cases or less. In about one half of the cases I have seen in which splenomegaly has been found the liver has also been enlarged. I do not know whether these reactions represent a complication or a defense mechanism on the part of the reticulo-endothelial system. If the lymph glands are the first line of defense, the spleen and liver the secondary defenses, one should think twice before advising splenectomy. Only temporary benefit was noted in one such case, probably the nonspecific temporary improvement any surgical operation may provide. The studies of Singer and of Felty, I believe, help to support the infectious theory, for such tissue responses, whether they are complications or defense reactions, are more suggestive of reaction to infections than to a metabolic or endocrine affair.

DR. H. M. CONNER, Rochester, Minn. There are certain indications for splenectomy that nearly every one accepts. One is the presence of Banti's disease, another, purpura hemorrhagica, and still another, hemolytic icterus. In these diseases, especially the latter two, splenectomy usually gives symptomatic cure. I doubt whether any disease in which blood cultures are positive, such as Dr. Singer showed today, will respond to splenectomy. It seems likely that the spleen may be a reservoir of bacteria in these cases, but to remove that reservoir in the presence of such widespread distribution of the organisms might be detrimental and almost certainly would not be beneficial.

DR. C. W. BALDRIDGE, Iowa City. I have seen two patients with a syndrome similar to that described by Felty. These two patients may have had Banti's disease with arthritis, since one had definite cirrhosis of the liver and both developed ascites. Does Dr. Singer wish to imply that this disease began eight years before death as a bacteremia or septicemia or that the latter was superimposed on a disease characterized by chronic leukopenia?

DR. M. A. BLANKENHORN, Cleveland. The chairman is interested in the fact that in both patients the "findings in the heart were the same" and that Aschoff bodies were described only in the first case. Perhaps Dr. Singer omitted mentioning Aschoff bodies in the second case. If Aschoff bodies were found only in the first case, will Dr. Singer say whether he and Dr. Jaffe consider the first case as presenting rheumatic fever and the second case as not presenting rheumatic fever?

DR. HARRY SINGER, Chicago. I agree with Dr. Hench that splenectomy in the presence of a sepsis is likely to do much more harm than good. In suggesting that the spleen might act as the focus of infection I was merely attempting to reconcile or explain the improvement in Hanrahan and Miller's patient following splenectomy. Whether or not the immediate beneficial results will continue remains to be seen. The question asked by Dr. Baldridge as to whether the sepsis demonstrated at autopsy was the primary disease is pertinent. The evidence for assuming that the sepsis lenta was of long standing in the cases presented is indicated by the character of the changes involving particularly the reticulo-endothelial system. These changes are the ones observed in cases of subacute bacterial endocarditis having an established duration of many months or even several years. Furthermore, the histologic features observed in the extirpated spleen in the case described by Hanrahan and Miller are practically identical with those found in the spleens obtained at autopsy in my two cases. Splenectomy was performed by Hanrahan and Miller while their patient was comparatively well. Dr. Blankenhorn asked regarding the specificity of Aschoff nodules found in my first case. Dr. R. H. Jaffe, our pathologist, has accumulated convincing evidence to show that the same organism can produce subacute bacterial endocarditis and rheumatic fever. The type of lesion produced is dependent on the defense reaction of the host rather than on a selective strain or type of streptococcus. I have seen Aschoff bodies in several cases of subacute bacterial endocarditis, sepsis lenta and scarlet fever in which there was no reason to assume the presence of a coexisting rheumatic infection. Aschoff bodies cannot therefore be considered pathognomonic of rheumatic fever.

(To be continued)

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers to THE JOURNAL in continental United States and Canada for a period of three days. Periodicals are available from 1925 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Spondylolisthesis and Prespondylolisthesis—Kleinberg states that prespondylolisthesis and spondylolisthesis are due to a congenital defect in the laminae of a lumbar vertebra, as a result of which the posterior arch of the vertebra is connected to the body only by fibrous tissue. The diagnosis of prespondylolisthesis is made by finding a defect in the laminae of the lumbar vertebra without any displacement of the body. The clinical symptoms include pain and weakness of the back and a variable degree of disability. A marked lordosis should make one suspect the existence of a prespondylolisthesis. When the diagnosis of prespondylolisthesis is established, fusion of the vertebrae should be advised for the purpose of preventing an actual dislocation. Spondylolisthesis is now being recognized with increasing frequency as an important cause of disability of the back. The signs, symptoms and roentgen observations of spondylolisthesis vary in degree. The subjective symptoms are rarely in direct proportion to the degree of bony deformity. Spondylolisthesis may exist for many years without causing symptoms or disability. When symptoms are present they may be relieved by external support of the back or in the more resistant cases by fusion of the vertebrae. In all cases in which operations were performed the posterior arch was found to be abnormally movable and minutely connected to the vertebral body only by fibrous tissue. The patients operated on were relieved of their symptoms.

Calcification of Mouse Carcinoma with Viosterol—Spies and Lyman investigated whether viosterol might produce calcification of an actively growing carcinoma and if so what effect it had on the generalized deposition of calcium in the viscera might have on the biologic behavior of the tumor and its host.

Results demonstrate that abnormal amounts of calcium were deposited in the experimental tumor and in the viscera of mice that were given intraperitoneal injections of viosterol over a period of from twenty-nine to sixty-one days. The longer the interval of time the greater was the intensity of calcification. The authors also observed that the mice which were given only the usual diet did not show calcium by the von Kossa histologic method except to a minor degree in two instances, these being limited to the tumor and probably due to viosterol secured by coprophagy. Necrosis of the neoplasms seemed as marked in the control animals as in those which had been given large amounts of viosterol. Sesame oil alone had no effect on the deposition of calcium in either the neoplasm or the organs. The natural course of the Thoracic carcinoma did not seem to be influenced significantly by the giving of large amounts of viosterol. After approximately thirty-four days the toxic effects of the activated viosterol were manifested in obvious derangements in the general condition of the animals.

Kitten Carriers of Microsporion Felineum—Davidson and Gregory state that in approximately half of the outbreaks due to Microsporion felineum some evidence indicated that infection had occurred from a cat or a dog. A boy, aged 5 years, became infected with M felineum. The first lesions appeared from two to three weeks after he had been given an apparently healthy kitten. When the kitten was examined under ultraviolet rays passing a filter of Wood's glass, fluorescent hairs were observed which proved to be infected with the same species of fungus as that infecting the boy. The patient, while undergoing treatment was given a healthy kitten to play with. In from three to four weeks this animal developed a typical ringworm lesion on the nose. A third kitten was artificially inoculated in the ear with M felineum. After the resulting lesion had healed a few fluorescent infected hairs remained around the eyes during three months and the animal is considered to have been, during this period a ringworm carrier. The authors suggest the extension of the fluorescence test to detect Microsporion infection in cats and kittens as a practical prophylactic measure.

Blood Tests in Tuberculous Patients—Cummins devised a micro method for the sedimentation test which is applicable to a sample of blood collected by pricking a finger. The same sample of citrated blood is used after the reading of the height of the blood cell column at the end of one hour, for the estimation of the total leukocytes, and the author has satisfied himself that the count remains practically unaltered for at least twenty-four hours. The enumeration of lymphocytes

and monocytes is carried out on a dry film stained by Leishman's method and is combined with the estimation of the von Borsdorff (Arnieth) count. He claims that these methods afford a valuable amplification to the grading of cases undergoing sanatorium treatment, and that they are invaluable in estimating the results of gold therapy and other new methods of treatment.

Bacterial Variation—Rettger and Gillespie state that *Bacillus megatherium* is extremely susceptible to changes in environment, giving rise to morphologic types that vary over a wide range from the more nearly "normal" to most extreme forms. On the transfer of cultures that have undergone such cellular transformation to the usual fresh culture medium the organism again assumes its regular cell outline and orientation. In old cultures pronounced autolysis is another important feature, and at times empty cells may be seen which resemble flattened tubes or 'sausage skins' and which are firm and highly resistant to mechanical injury. These must be regarded as definite cell envelopes or membranes. Repeated attempts to demonstrate the occurrence of a filtrable phase or phases in *Bacillus megatherium*, *Alcaligenes abortus* and *melitensis* and the organisms commonly present in raw sewage resulted in failure.

Effects of Alternate Suction and Pressure on Blood Flow to the Lower Extremities L. M. Jandis and J. H. Gibbon Jr. Philadelphia—p. 925

Effect of Digitalis on Venous Pressure—Ryland made thirty-seven control and eighty-two experimental observations on the venous pressure before and after the administration of digitalis (in single full doses) in nine trials on eight normal subjects. He found that, in normal human beings and dogs, digitalis causes a decreased cardiac output and a decreased venous pressure. The greatest effect occurs at about twenty-four to thirty-two hours after the administration of the drug, with a return to normal levels in from seventy-two to ninety-six hours. The observed changes support the hypothesis that digitalis owes its action to a peripheral effect, probably on the hepatic vein radicles, in reducing the return flow of the blood to the heart. The hypothesis that the digitalis action follows changes in cardiac tone is negated by all available data. Digitalis bradycardia is not due to the fall of venous pressure. The slowing of the heart, by causing the normal increase in venous pressure, partially conceals the effect of digitalis in reducing the return flow of the blood to the heart.

Creatinine and Urea Clearance Tests—In order to estimate the range of creatinine clearance in normal persons under conditions of hospital and private practice Hayman and his associates performed fifty-nine clearance tests on fifty-nine apparently healthy persons. In forty-five, only a single test was made and in fourteen from two to twenty-one clearances were determined. The authors compared the creatinine and urea clearance tests in normal persons and in patients presenting a history of chronic interstitial nephritis. The mean creatinine clearance in the 130 observations of the fifty-nine normal subjects was 148 cc per minute. The variability of the two tests from the mean normal was approximately the same. In patients presenting chronic interstitial nephritis the creatinine and urea clearance tests are generally equally reduced in relation to the average normal. The authors were unable to demonstrate any practical advantage in the creatinine test to compensate for its greater technical difficulty.

Serum Treatment of Streptococcal Pneumonia—Amoss and Craven report eight cases of β hemolytic streptococcus pneumonia in which antistreptococcus serum was administered and all the patients recovered. Three of the four patients treated by intravenous and intramuscular injections of the serum developed streptococcal empyema. Instillation of the serum into the pleural cavity in two patients presenting effusion apparently prevented infection of the fluid in one, and in the other it cleared the infected fluid of organisms in forty-eight hours. Instillation of the serum into the pleural cavity in two patients having empyema cleared the fluid of the hemolytic streptococcus but not of the pneumococcus, group IV, which appeared simultaneously with the disappearance of the streptococci. The results of tests by precipitins, toxallergen neutralization and mouse protection tests suggest a rational immunologic basis for specific serum treatment.

Precipitin Reaction in Yellow Fever—According to Hughes, serums taken from monkeys recently recovered from severe yellow fever infections possess a precipitin capable of reacting with a precipitinogen that occurs in the blood of monkeys during the period of acute illness. This precipitinogen is not the virus of yellow fever but appears to be associated with a protein of the albumin fraction. Its concentration reflects the severity of illness. It disappears with recovery after stimulating the formation of a precipitating antibody. This resulting precipitin is entirely independent of the protective antibody resulting from an infection. A similar precipitin occurs in the serum of human beings recently recovered from a severe yellow fever infection. This precipitin reacts with the precipitinogen occurring in the blood of monkeys during the acute phase of the fever.

Congenital Osteosclerosis—Robertson presents a typical case of congenital osteosclerosis in which the striking feature is the large amount of vitamin D which the child received. The idea that osteosclerosis may represent the extreme in the healing of a rachitic process has been advanced but is generally discounted since rachitic changes have not been demonstrated in these cases. The administration of vitamin D may accelerate the progress of the condition. In this connection the chemistry of the blood is of interest. Two determinations of phosphorus gave low values and the second determination after thirteen months without added vitamin D in the diet gave a value suggestive of active rickets. The author refutes the possibility that changes of the bone in this condition are secondary to or simultaneous with changes of the bone marrow by the fact that fairly extensive osteosclerosis has been reported in adults without anemia and with no abnormality in the blood picture. The blood picture of the anemia of congenital osteosclerosis

has many features in common with the blood picture of Cooley's erythroblastic anemia. In both there is a gradually increasing anemia in the face of evidence of intense stimulation of the bone marrow and regeneration but in the former there is increased calcification and, in the latter, decreased calcification. The situation suggests the possibility that the two conditions may be closely related and that osteosclerosis may be secondary to osseous rarefaction. The author believes that, in Moore's adult case of sickle cell anemia, the skull showed the characteristics of the skulls described by Cooley, while the short bones showed osteosclerosis. An analysis would seem to indicate that intense stimulation of the bone marrow may cause rarefaction of the bone that osteosclerosis may follow osseous rarefaction that osteosclerosis may occur without demonstrable changes of the bone marrow, but that the weight of evidence favors the conception that sclerosis of the bone or petrification in congenital osteosclerosis is the primary condition and that changes affecting the bone marrow and the hemopoietic system are secondary.

Phrenic Nerve Paralysis—A study by Stein of nine cases of phrenic nerve paralysis associated with Erb's paralysis discloses that the great majority of cases are on the right side. The prognosis is favorable as regards restoration of function in the early days of life but appears to be less so if treatment is delayed from two to three months. Even then the prognosis as to life is not unfavorable as shown by the cases of Remic and Epstein. Paralysis of the phrenic nerve should be looked for in all cases of Erb's paralysis. The author suggests that in view of Kofferrath having been the first to describe the syndrome of Erb's paralysis with phrenic nerve paralysis the name 'Kofferrath syndrome' be given to the condition.

Myelosarcomatosis—Kunstadter reports the case of a child of 6½ in whom the essential features were multiple malignant tumors throughout the skeletal system, gastro-intestinal tract, kidneys, pancreas and dura mater, which histologically gave the appearance of undifferentiated myeloid tissue. The blood contained many atypical cells that resembled young lymphocytes but may have been myeloid in origin. The clinical and pathologic diagnosis in this case presented many difficulties. The appearance of multiple tumors in the skull, proptosis, roentgen evidence of rarefaction and destruction in the membranous and long bones, marked anemia, severe emaciation and cachexia suggested the possibility of generalized sarcomatosis (the primary focus unknown), chloroma, multiple myeloma, sympathetic blastoma of the Hutchinson type, generalized xanthomatosis (Christians syndrome), lymphosarcoma, atypical leukemia and leukosarcomatosis. The author believes that this case falls into the group of complicated leukemia and appears to substantiate the blastomatous nature of certain forms of leukemia.

Pyo-Urachus—Stevens reports a case of pyo-urachus which differs from most instances of inflammation of the urachus in that 1. There was no opening leading to the umbilicus or to the bladder. 2. The urachus had not retracted downward as usual but still remained attached to the umbilicus in adult life.

3. The urachus had remained patent at its upper portion, as proved by the islands of epithelium found, whereas it had apparently become merely a cord of smooth muscle and fibrous tissue at the lower end, with no sign of epithelium or of a lumen.

4. The inflammation was confined to the upper part of the urachal structure, with no involvement of the bladder end.

Treatment of Urethral Strictures—Riba and Sanner feel that small caliber strictures can be enlarged easily with only one electrosection treatment, that is, the introduction of a special electro-urethrotome into any strictured urethra, provided a filiform bougie can be passed. The urethrotome carries a cutting loop, which may be expanded to a desired caliber just proximal to the stricture or strictures. The cutting current is then turned on and the urethrotome withdrawn. There is no shock or pain. There is no active hemorrhage following this operation. The authors do not recommend this procedure to displace the use of urethral sounds. They believe that the usual course of urethral dilatations may be materially shortened if the strictures of small caliber are sectioned first, and they have found that subsequent sounds may be passed readily and without apparent difficulty. There has not been any indication that more scar tissue is likely to form following an electro-urethrotomy. In cases of strictures and infiltrations of large caliber this procedure is of little value. In a patient who has a strictured urethra and for some reason or other (renal colic, hematuria or injuries) needs an immediate cystoscopy, they believe that this method of handling the stricture would be the procedure of choice. From an economic standpoint, many patients can be kept out of a charity-bed hospital or their hospital stay may be reduced to a minimum of a day or two.

Roentgen Treatment of Plantar Warts—Ledy and Johnson state that before roentgen treatment is given the superficial keratotic layers should be pared off. A small hole is punched in a piece of lead foil 1 mm thick and enlarged to the size of the wart. The lead foil is strapped to the foot with adhesive tape, lead rubber is used to protect the outlying regions. A mechanical rectifier and Coolidge tube are used. Low voltages, 80 peak kilovolts and 100 peak kilovolts without filter are most frequently employed, 100 peak kilovolts or 110 peak kilovolts are occasionally used with 2 mm of alumi-

num filter, and 135 peak kilovolts with 4 mm of aluminum filter for the rare, large, infiltrating lesions. The focal skin distance used is 9, 12 or 16 inches. The time is changed proportionately. The milliamperage employed is 5, 6 or 8. The total dose varies greatly from less than 0.7 to 5 skin erythema doses (192 to 1848 roentgens). After the treatment is given, a pad is placed around the wart to relieve pressure. This pad is changed twice a week, and 20 per cent sulphonated bitumen in hydrous wool fat is often employed to keep the tissue soft. With lighter doses the treatment is repeated at intervals of one or two weeks for two or three times, but when the heavy doses are used the treatment is not repeated before two months, and then only once if indicated.

Treatment of Pulmonary Tuberculosis—Stivers states that a complete collapse is obtained in approximately 10 per cent of all cases of pulmonary tuberculosis treated by artificial pneumothorax. In another 10 per cent a selective compression of the diseased areas gives satisfactory results. In the remaining 80 per cent, compression of the lung is ineffectual owing to pleural adhesions which hold the lung to the chest wall. It has been found that in many of these cases the operative procedure of intrapleural pneumolysis, or cutting of these adhesive bands, gives the desired collapse. The author is using a thoracoscope with the lens at an angle of 45 degrees, directed more toward the tip of the instrument. With his thoracolum the light can be guided to any part of the cavity in the chest and in combination with the unlighted thoracoscope, can be used to determine the consistency of the bands. Two principal types are in use for severing the adhesions: the galvanocautery, a hot cutting point, and the endotherm, a cold coagulating and cutting electrode. The color of all adhesive bands is significant. In case an adhesion contains lung tissue it is preferable to coagulate an area around the insertion of the band on the chest wall at the first operation, and at a later operative date complete the cutting of the adhesion. In coagulating large adhesions it is advisable to use a comparatively weak current for a longer period rather than a stronger current for a brief time, for the latter current might occasion quick dehydration or even carbonization of the tissue. This would limit the field of desired coagulation and possibly be instrumental in the causation of secondary hemorrhage. The majority of adhesions are noted at the apex, posteriorly or a few centimeters below this location, then at the posterior lateral wall and last at the anterior wall. Occasionally a band holding the lung to the diaphragm is defined and is severed with difficulty, owing to the motion of the diaphragm. The stringlike fibrous band, the short thick fibrous band and the broad fan-shaped adhesion can be destroyed if they are not complicated by blood vessels, lung substance, caseous nodes or extension of the formation of a cavity into the band.

- *Sulpharsphenamine in Vincent's Angina H J Harris Westport—p 1000

Sulpharsphenamine in Vincent's Angina.—Harris states that in about 500 injections of sulpharsphenamine of various brands, given to patients with Vincent's angina during the 1932 epidemic, no noticeable reactions occurred except for an occasional patient who was actively nauseated or vomited during or immediately after the injection. Since reporting the series, the author has had five cases of toxicity and reactions, which he reports. These cases occurred within a few months, with the same technic and with various brands of sulpharsphenamine. In the many sporadic cases of a less severe and less infectious but of a stubborn nature that fail to respond to local measures such as potassium chlorate, sodium perborate and their flavored proprietary preparations, and since the disease may be so serious in some of its manifestations, the author has continued to use the intravenous injection of sulpharsphenamine mentioned in his original communications, realizing the possible reactions that might occur. It is unsafe to use this drug unless one is prepared to administer sodium thiosulphate intravenously at the first sign of a severe reaction or advancing arsenical dermatitis. With proper precautions, sulpharsphenamine can be used with reasonable safety in intractable cases of Vincent's angina, as in syphilis. It is essential to keep the patient under observation for at least fifteen minutes after the injection, to give sodium thiosulphate when indicated, and to be prepared for late reactions, such as dermatitis, which are successfully treated if seen at once.

Parathyroid-Thyroid Syndrome.—Enfield reports calcification of the parathyroid body in a Negro of 17 who complained of drowsiness noticed four years ago. This has continued and for the past four months the somnolence has been more pronounced. At times the patient noticed fullness and heaviness in the head and occasional blurring of vision. There was obstruction of the right nostril and a granular pharyngitis. The thyroid was readily palpated and gave a fibrous resistance. Examination showed the lungs and heart to be normal. Blood pressure was 90 systolic and 70 diastolic, with a pulse rate of 60. Ophthalmoscopic examination showed normal fundi with vision 5/15 in the right eye and 5/9 in the left. A roentgenogram of the skull showed the sella turcica to measure 14 by 65 mm. The sella was traversed by a calcified network and the chnoids were joined by a bony bridge. The basal metabolic rate was minus 17.8 per cent. The blood sugar was 97 mg per hundred cubic centimeters rose to 155 mg in one hour and fifteen minutes after the ingestion of 150 Gm of dextrose and returned to 105 mg within two hours and fifteen minutes. No sugar was found in the urine. Urinalysis tests of the renal function blood counts Wassermann reaction and the fluid intake and output were normal. Treatment consisted of thyroid extract

006 Gm with pituitary substance 0.12 Gm in a capsule three times a day. The patient was under observation for eight weeks and when last seen had been working as a stevedore, entirely free from drowsiness. Neither trauma nor tuberculosis seemed active.

Chemical Composition of Amniotic Fluid.—Cantarow and his associates made chemical studies of amniotic fluid and maternal blood obtained simultaneously from thirty-six women in the seventh to the ninth months of normal pregnancy. The protein content of the maternal serum ranged from 4.07 to 7.5 Gm per hundred cubic centimeters. That of the amniotic fluid varied from 0 to 1.5 Gm averaging 0.53 Gm per hundred cubic centimeters. The nonprotein nitrogen content of the maternal blood ranged from 13.76 to 36 mg, averaging 23.98 mg per cent and being definitely lower than the reported values for normal nonpregnant women. The nonprotein nitrogen concentration of the amniotic fluid varied from 13.6 to 37.5 mg, averaging 24.25 mg and being higher than the corresponding maternal blood values in fifteen and lower in twenty instances. The uric acid content of the maternal blood ranged from 1.6 to 4.6 mg averaging 3.05 mg per hundred cubic centimeters. That of the amniotic fluid varied from 2.06 to 8.96 mg, averaging 4.54 mg per hundred cubic centimeters and exceeding the uric acid concentration of the maternal blood in thirty-one cases. The sugar concentration of the blood ranged from 48 to 108 mg averaging 84 mg per hundred cubic centimeters. The sugar content of the amniotic fluid varied from 0 to 59 mg averaging 19 mg per cent. The calcium content of the maternal serum ranged from 8.2 to 12.5 mg averaging 9.82 mg, that of the amniotic fluid varied from 3.26 to 7.84 mg per cent averaging 5.46 mg. The inorganic phosphorus content of the maternal serum ranged from 3.5 to 5.7 mg averaging 4.3 mg per hundred cubic centimeters. The values for amniotic fluid phosphorus varied from 1.2 to 5.4 mg averaging 3.1 mg and

exceeded the phosphorus concentration of the serum in four instances. The authors compare these data with corresponding observations on cerebrospinal fluid and transudates and believe that the amniotic fluid cannot be regarded as a pure dialysate of maternal blood plasma.

Dysfunctional Uterine Bleeding—Smith and Rock treated twenty-four patients who complained of menorrhagia and thirty-six who complained of metrorrhagia with antuitrin S. The optimal dosage in this group was from 20 to 40 cc of antuitrin S given in amounts of from 3 to 10 cc over a period of from three to ten days. Twenty-eight patients were cured, twenty-two were relieved and six were not benefited. The cessation of bleeding accompanied treatment so often and in many cases so rapidly as to leave little doubt of the specificity of the hormone, especially when the variable potency of the preparations was considered. A limited number of laboratory observations have suggested a clue concerning the mechanism of the therapeutic action of this hormone, i. e., the possibility of a direct action on a hypophyseal hormone.

Pancreatic Extract in Treatment of Angina Pectoris—Milliken calls special attention to the use of an insulin free pancreatic extract in the treatment of angina pectoris. It is so diluted that in biologic assay 0.1 cc neutralizes 1 microgram of epinephrine or the amount of antiepinephrine necessary to counteract 0.001 mg of epinephrine. This is termed one unit. Pancreatic extract has been used in forty cases of angina pectoris. The author has used it in seven additional cases. In the forty-seven cases, the extract was found to be of no benefit in 12.76 per cent, 27.65 per cent showed moderate benefit and marked benefit was obtained in 59.67 per cent of the patients treated by the intramuscular injection of the substance. The amount of extract required to give relief is not constant but gives a fairly clear idea of the severity of the angina. Mild cases require from 120 to 740 units to obtain relief, while the more severe cases may require as many as 5,000 units. The best plan of treatment has been daily injections of from 60 to 120 units of the extract for a period of ten days. Then if the symptoms have been relieved the time interval is extended between doses for from one to two days. The extract is used until the patient remains free from all symptoms for a period of six months.

Hypertension and Intestinal Toxemia—Johnson cites his experience with five carefully selected and closely observed cases of early essential hypertension over an average period of two years. He observed that intestinal toxemia is associated with all cases. Treatment that relieves the toxemia reduces the blood pressure. The pressure rises again shortly if the toxemia is allowed to return, and is again lowered with the restoration of normal intestinal elimination. A reasonable level of pressure can be maintained perhaps indefinitely, provided the patient is kept free from toxemia and from emotional stresses. The importance of the establishment of intestinal toxemia as an etiologic factor in hypertension lies not so much in the possibility of the cure of the cases already established as it does in prospects of prophylaxis against the development of this malady in predisposed persons.

 *Hemolytic Streptococcal Meningitis with Recovery Case Hilditch Rockett—p. 196

Rare Primary Osseous Dystrophy—Ellman presents a case of unusual type of primary bone dystrophy, with secondary manifestations in the joints mainly of the toxic or so-called rheumatoid type of arthritis. A careful search of the literature shows reports of an almost identical condition described in two cases by Morquio and in one by Meyer and Brennermann. As in Morquio's cases there was a history of the parents being first cousins. Because the author's patient is an only child, the familial tendency cannot be confirmed. The gross deformity of the body and the points of resemblance of other parts of the skeleton point to the condition being a clinical entity that is distinctive and almost identical with the cases of Morquio and Meyer and Brennermann. The underlying pathogenesis is not easy to explain. The parents of the patient were first cousins and the lower blood calcium, blood phosphorus and blood phosphatase is undoubtedly an important factor in what Morquio described as a serious disturbance of osteogenesis. The question of an endocrinal change (parathyroids?) being the primary factor has to be considered. The essential feature of generalized bony decalcification points to the possibility of a congenital metabolic disturbance. While the mother is convinced that the condition followed measles it is more likely, from the history, that measles aggravated the already existing changes in the skeleton bringing the condition more vividly to her notice.

Hemolytic Streptococcal Meningitis—Rockett reports the case of a boy, aged 2½ years who was admitted to the hospital with whooping cough and bronchopneumonia. The temperature dropped to 99 F and remained at or near this level for the next fortnight. During this period the patient's general condition was poor; he coughed whooped and vomited at fairly frequent intervals and the lungs showed signs of extensive bronchitis. Twenty-two days after admission the temperature commenced to rise reaching 103 F the following day. In the absence of any other clinical manifestations, apart from bronchitis it was assumed that the rise of temperature with accompanying increase of pulse and respiration rates was indicative of a recrudescence of bronchopneumonia. Three days later, rigidity of the neck was first observed. There was no retraction of the head and Kernig's sign was negative. On otologic examination, both tympanic membranes were found to be normal. On lumbar puncture turbid fluid under slightly increased pressure was obtained. Both direct smear and culture gave a negative result. From the fluid obtained on the following day a profuse growth of hemolytic streptococcus in pure culture was grown. Treatment by antiscarlatinal serum intrathecally and intramuscularly was immediately begun. Intravenous administration of serum was found to be impracticable without cutting down on a vein. Recovery was considerably retarded by severe paroxysms of whooping cough during which suffocation frequently appeared imminent.

 Multiple Gangrene of the Skin Report of Three Cases J. H. T. Davies—p. 341
 Keratosis Punctata at an Unusual Site (Naevus Unius Lateris) J. Beatty—p. 346

Autohemotherapy—Burgess used autohemotherapy in cases of psoriasis, eczema, varicose dermatitis with sensitization rash, chronic urticaria, toxic erythema, furunculosis, idiopathic generalized pruritus and Besnier's prurigo. Acute psoriasis was cured or greatly improved within two months. One case cleared up within four weeks. The subacute and chronic cases were less satisfactory, half the cases being improved but the rest did not benefit from the treatment. All patients were treated

locally with 2 per cent ammonium hydrophosphate and salicylic acid in zinc paste. Consistently good results were obtained in cases of varicose dermatitis of the leg in which a generalized sensitization eruption had occurred, all the patients treated were known to be cured with the exception of three who ceased to attend. In one case the sensitization eruption, which had been present for several months, disappeared in ten days, only two injections being given. The sensitization rash usually disappears after two or three injections, but in most cases the original patch of varicose dermatitis remains unaltered. Eczema failed to improve in 60 per cent of the cases as a result of autohemotherapy, but the remainder were cured or greatly improved. The sensitization eruption occurring in the course of varicose dermatitis treated by autohemotherapy gave the most satisfactory results. Five cases of chronic urticaria were treated of which two were improved. Three cases of toxic erythema were treated and cured. Three cases of furunculosis cleared up after treatment, but a case of idiopathic pruritus failed to respond. In cases of Besnier's prurigo temporary improvement with a diminution of the irritation takes place, but there is no alteration in the appearance of the eruption. Treatment with intradermal injections of autoserum in a few cases of acute psoriasis nummular eczema and angioneurotic edema was not as beneficial as autohemotherapy. The patients who were relieved by autohemotherapy and autoserotherapy gave positive skin reactions to their proteoses, while after successful treatment the skin reactions were negative. Those not relieved had either given negative reactions before treatment or continued to give positive reactions after treatment. The author suggests that it is possible that the blood in these patients contains antigens and that the injection of blood or serum leads to desensitization.

Metastases in Breast Cancer Problem of Prevention F Hernaman-Johnson—p 468

Metastases in Breast Cancer—Hernaman-Johnson says that metastases may arise from cells which have escaped operative removal or death by radium or they may be already present in embryo in the spine or elsewhere at the time of operation. It is not possible to kill all malignant cells widely scattered as they may be by any form of radiation but suitably applied roentgen treatment will help to stimulate the body itself to deal with them. The fact that the method of attack is indirect makes it imperative that the response of the body tissues should not be exhausted; hence one should not aim at doing everything by a single course of treatment but should give treatment from time to time over a period of years. Agents that act solely by affecting the body as a whole should not be neglected. Of these ultraviolet radiation is of proved value but all measures that provide mental and physical health are of importance and the general effect of roentgen rays themselves must not be left out of account. Radiation therapy, however modified and improved may never be an ideal weapon against metastases. But at least its possibilities in this direction should be fully explored as at the moment it is the only line of treatment that holds out any hope of lessening the death rate from this cause.

*Purulent Meningitis with Recovery Case Presenting Certain Resemblances to Meningitic Form of Poliomyelitis J A Cruickshank—p 44

Purulent Meningitis with Recovery—Cruickshank reports a case of meningitis that occurred in a healthy young man eight months after an attack of influenza. The cerebrospinal fluid was frankly purulent containing large numbers of polymorphonuclears but no organisms could be found either by direct examination or on culture. There was no focus of infection in the ear or nasopharynx. After an irregular fever lasting about two weeks the illness ended in complete recovery. The author discusses the diagnosis with particular reference to the possibility of the meningitic form of poliomyelitis and concludes that the case was one of purulent meningitis of unknown origin. All cases of so called benign purulent meningitis and cases of incompletely developed abortive or meningitic poliomyelitis should be observed carefully in the convalescent stages for evidence of paralysis or dementia paralytica and should be studied from the epidemiologic aspect. When there is no definite evidence of the infection having been due to the virus of poliomyelitis, it does not seem justifiable to make any more exact diagnosis than one of purulent meningitis of unknown origin. The objectionable term 'aseptic meningitis' is best avoided.

Treatment of Malaria—From a study of thirty eight cases of malaria treated with atebrin (an amino acid derivative) Chopra and his associates draw the following conclusions. 1 Atebrin is an effective drug in the treatment of Indian strains of malaria. Its destructive action on the asexual forms of benign tertian malignant tertian and quartan types of malaria is about equal and the schizonts disappear from the peripheral circulation after the administration of three tablets of 0.1 Gm for two or three days. 2 The sexual forms or gametocytes are more slowly acted on than the asexual forms. The gametocytes of the benign tertian and quartan types are readily destroyed and degenerative changes can be observed in them shortly after the administration of the drug is started. The gametocytes of the malignant tertian type are not touched at all. 3 The drug is effective in doses of 0.1 Gm three times a day for five days. In the majority of cases such a course is effective but in some cases it may have to be repeated after an interval of a few days. The drug can also be effectively given intravenously in doses of 0.1 Gm dissolved in from 1 to 2 cc of distilled water when the number of parasites in the peripheral blood is large. 4 In chronic types of malaria the drug is effective and produces a rapid reduction in the size of the spleen. 5 It is reported to prevent relapse but the evidence at the authors' disposal shows that this is not the

case with Indian strains of malaria. Its prophylactic value is similar to that of the cinchona alkaloids. 6 In blackwater fever and in patients in whom the administration of quinine produces hemoglobinuria, atabrin can be safely given. 7 The blood pressure is lowered in some patients during the administration of the drug but in the majority there is no effect. The pulse rate and respiration are not markedly affected. It has been used for patients suffering from endocarditis and myocarditis without ill effects. 8 The drug is largely excreted in the urine and can be readily detected. The excretion is not regular and goes on for three weeks or longer. There is a distinct tendency toward cumulative action of the drug. 9 It produces certain untoward effects, which are not serious. A profound feeling of general depression occurs in some patients. A slight yellow tinge of the skin and conjunctiva was observed particularly in those patients in whom excretion from the kidney is hindered for some reason. Slight epigastric pain, a feeling of uneasiness in the stomach, headache and loss of appetite and diarrhea sometimes occur when the drug is being administered. These as a rule stop when the drug is withheld. 10 The action of atabrin closely resembles that of the cinchona alkaloids, and the introduction of this drug is a distinct advance in the treatment of malarial fevers in India.

Tropical Typhus Related to Scrub Typhus—Martin and Anderson describe a case of continued fever contracted in Burma, exhibiting symptoms and signs suggestive of tropical typhus. Repeated Widal tests gave no evidence of infection by the enteric group, while the Weil-Felix test with proteus OX19 was persistently negative. The serum of the patient taken on the eighteenth day of the illness strongly agglutinated the Kingsbury strain of proteus, OXK, a strain of proteus which reacts specifically with the serum of cases of scrub typhus occurring in Malaya. Therefore the authors considered their case to be one of tropical typhus belonging to the same serologic variety of the typhus-like fevers as the K group, or scrub typhus. The clinical features of the case, with a history of a painful insect bite, and the later serologic observations strongly suggested to the authors that they were dealing with a variety of tick typhus forming another of the rural group of typhus-like fevers, a group which includes tick typhus of India and scrub typhus of Malaya. So far as they are aware this is the first occasion on which this variety of tropical typhus has been reported and demonstrated serologically. They suggest that the introduction and use of the Kingsbury strain of proteus, in addition to proteus X19 for the serologic diagnosis of typhus-like fevers, will probably show that there exist two groups of these fevers, one of which has heretofore remained undiagnosed by laboratory methods.

Immunity to Tuberculosis—Willis studied, particularly on solid mediums, the effect of unheated rabbit blood on the growth of human and bovine tubercle bacilli. Rabbit's blood was obtained and incorporated into mediums by drawing 4 cc. of a 25 per cent solution of sodium citrate made from physiologic solution of sodium chloride (0.85 per cent) into a 25 cc. syringe into which the blood was then aspirated directly from the heart to a total mixture of 20 cc. Blood thus obtained was added to warm glycerinated agar medium in the proportion of 1:2 (15 cc. of blood and 3 cc. of medium) and the mixture allowed to cool in a slant. Several lots of this medium were planted with human (H37) and a like number with bovine (B1 and B44) tubercle bacilli along with equal numbers of tubes containing the same batch of medium to which no blood had been added. Also a few tubes of each were planted with avian tubercle bacilli. The cultures were observed at regular intervals of from five to eight days until growth was complete. This varied from three to six weeks. Both human and bovine tubercle bacilli grow luxuriantly in mediums to which citrated rabbit's blood has been added. The addition of this ingredient to mediums neither unduly stimulates the growth of bovine bacilli which are pathogenic for rabbits, nor inhibits the growth of human bacilli to which rabbits are resistant. These types grow equally well on mediums prepared with rabbit's flesh instead of beef. When added to solid medium, sodium citrate stimulates moderately the growth of tubercle bacilli. Both human and bovine tubercle bacilli are carried over the rabbit's body after subcutaneous inoculation in the groin. Each is recoverable from the lungs and kidneys five days after inoculation.

Id. Report III. Relationship Between the Function of the Reticulo-Endothelial System and Retention of Sodium Chloride in the Tissues H. Saito—p. 72

Influence of Dextrose on Gastric Juice—The studies of Matsuyama bring out that, when dextrose is previously administered intravenously the gastric secretion taking place on the intake of food is inhibited in human beings just as in dogs, but the degree of the inhibitory effect is not marked. When the solution of dextrose is previously injected subcutaneously, the gastric secretion taking place on the intake of food is conspicuously inhibited and sometimes suppressed. This inhibitory effect on the secretion is due not only to the rise in the level of the blood sugar but to the excitement of the centrifugal sensory nerves. Solution of dextrose injected intravenously at the time when the gastric secretion on intake of food was taking place exerts no inhibitory action on the gastric secretion. And, further whatever the concentration of the solution of dextrose and whatever the amount of dextrose, the course of the gastric secretion is not affected.

Fetid Colic Syndrome in Children—Nobecourt describes the fetid colic syndrome that occurs in infants and children (rarely under 6 years of age) as a manifestation of abnormal putrefactive processes in the large intestine, which are favored by an abundance of insufficiently elaborated nitrogenous residues. A diet too rich in animal proteins and too poor in cereals, vegetables and fruits is usually the primary cause of the syndrome, but individual factors, such as dyspepsia, secretory disturbances of the gastro intestinal tract and a neuro-arthritis disposition, may play an important part. The most characteristic symptom is the fetid odor of the stools. Evacuation of the bowels usually occurs only every other day or every third or fourth day. Careful examination of the feces may disclose small masses of coagulated mucus, but blood is absent. In many patients the constipation gives way from time to time to a diarrhea in which two or three stools may be passed daily, and this condition may last several days. The fetid odor is accentuated during the periods of diarrhea. The aspect of the abdomen is generally normal. Palpation may disclose a sensitivity in the region of the large intestine, the ileocecal colon, the splenic angle of the colon or, more often, in the cecum. Modifications of the consistency and caliber of the colon are observed. Gastric succussion sounds and enlargement of the liver are frequently present. Symptoms of a hyposthenic gastric dyspepsia, often associated with the fetid colic syndrome, may be evidenced. Pallor, often cholemic, is observed. The children are generally thin, sad, apathetic and irritable, are easily fatigued and suffer from headaches. The evolution of the syndrome is essentially chronic, but acute exacerbations with fever may occur. The general symptoms often dominate the clinical picture and careful inquiry is necessary to reveal their cause. Treatment consists first of all in regulation of the diet. This comprises on the one hand the elimination or restriction of milk, meat and egg white with the substitution of buttermilk, yoghurt and kefir, and on the other hand the sole or predominant use of cereals, legumes rich in carbohydrates, and other vegetables and fruits. Medicinal treatment aiming at stimulating the digestive secretions, producing antiseptics of the large intestine, supplementing deficient digestive secretion and combating the constipation the general weakness and so on, should be given according to the individual indications.

- *Combined Pyretotherapy and Chemotherapy in Primary and Secondary Syphilis C Richet, Jr J Dublneau and F Joly —p 1649

Combined Pyretotherapy and Chemotherapy in Syphilis—Richet and his associates report clinical and experimental facts which seem to prove that pyretotherapy and chemotherapy combined can check a syphilitic infection more rapidly than chemotherapy alone. They obtained the cure of experimental syphilis in rabbits which arsenotherapy alone (in the same doses) could not have produced and which pyretotherapy (of the same intensity) could not have obtained with constancy. In clinical practice the authors employed their treatment in thirty-seven cases of recent syphilis, five cases of primary and thirty-two cases of secondary syphilis. Each injection of antisyphilitic medication (given in the usual doses) was followed on the same day or several days later by the injection of a substance producing hyperthermia usually Dmelcos' vaccine. The average hyperthermia of more than 39 C in all patients totaled twenty-five hours for from eight to eighteen injections. The rapid disappearance of adenopathies and particularly of syphilitic was noted. In some of the cases of primary syphilis the serum reactions became negative after five injections of antisyphilitic medication and in the thirty-two cases of secondary syphilis the serum reaction usually became negative after from eight

to sixteen injections. The exact mechanism of this therapy is still obscure but the demonstrated sensitivity of *Spirochaeta pallida* to heat is an important factor. In three patients presenting chancres each of whom received an injection of an arsenic preparation followed two hours later by an injection of Dmelcos *Spirochaeta pallida* had disappeared the next morning while the spirochete could still be demonstrated in a control patient.

- *Diathermy in Treatment of Gangrenous Pulmonary Abscess T Lucherini —p 1715
Calculous Bilateral Hydronephrosis Pyelolithotomy and Nephrolithotomy D Lioy —p 1721

Diathermy in Treatment of Pulmonary Abscess—Lucherini employed the following technic in treating gangrenous abscesses of the lung. Two lead electrodes about 0.5 mm in thickness, 18 cm in width and 25 cm in length are placed on the anterior and the posterior aspects of the side of the thorax corresponding to the seat of the pulmonary lesion, which is thus completely traversed by the diathermic current. The electrodes are fastened with large elastic bands and the patient is either half seated or lies prone. The intensity of the current varies according to the tolerance of the patient, generally from 1 to 15 amperes, and the duration of treatment is ten minutes for the first, twenty for the second and thirty for all succeeding treatments. One treatment is given every day. The author's patients received no supplementary treatment. The results proved satisfactory in all cases. The patients showed general improvement, increase of weight, disappearance of coughing, fever, pain, and hemoptysis, as well as diminution of the expectoration and of its fetid odor. Roentgenologic examination confirmed the improvement. The author maintains that by stimulating the blood and the lymphatic circulation and bringing energy into the tissues in the form of heat this method of treatment favors the resolution of the pathologic process, cleanses the focus of the disease and aids the recuperative powers of the tissues. The method is not advisable in acute forms of gangrenous abscess of the lung tending toward serious hemorrhages. The author believes that, even if the disease is not completely cured by this process, it improves the condition of the patient, reduces the extension of the gangrenous focus, renders the prognosis more favorable, stimulates the action of medical treatment and prepares the way for surgical intervention. The number of diathermic applications should correspond to the course of the disease and its symptomatology.

*Glycemia in Pulmonary Tuberculosis A Dalto —p 1004
Syphilitic Chancre of Gums of Extragenital Conjugal Origin Case M I Quiroga and A Sicardi —p 1026

Glycemia in Pulmonary Tuberculosis—Dalto performed the provoked hyperglycemia test in fifty-six patients having various forms of pulmonary tuberculosis without hepatic complications. The determinations were made one half hour, one hour and two hours after the oral administration of a 20 per cent solution of dextrose. The author concludes that in patients with grave febrile forms of pulmonary tuberculosis in evolution as well as in emaciated tuberculous patients there is hyperglycemia. In patients having stationary forms of pulmonary tuberculosis the glycemia is diminished but shows a tendency to become normal again. In patients suffering from subfebrile, sclerous forms of chronic evolution there is hypoglycemia and occasionally hyperglycemia. In patients whose tuberculous lesions follow a favorable course, with improvement of their general condition glycemia is diminished during the first determinations of the test and then rises to normal values without exceeding them. The author's results agree with those generally reported in the literature. He considers the variations of both normal glycemia and provoked hyperglycemia if not exactly an absolute mathematical criterion in the direct diag-

nosis and prognosis of pulmonary tuberculosis, at least a coadjutant element of great value in the indirect diagnosis and prognosis of the disease, as they are the manifestation of the profound changes which the carbohydrate metabolism suffers in those patients

Antisymphilitic Treatment of Lesions Suspected of Being Primary Syphilitic Lesions Without Corroboration of Diagnosis by Demonstration of Spirochetes? A. Musger —p. 1532

Fungicidal Action of Various Chemicals—Li Hsueh Yi calls attention to the high incidence of fungous infections of the feet. He mentions *Epidermophyton rubrum*, *Epidermophyton interdigitale* and *Trichophyton pedis* A and B as the most frequent causes. He investigated the action of various chemicals in experiments *in vitro* and found that Castellani's fuchsin dye, thymol, benzoic acid and salicylic acid have a powerful growth-inhibiting as well as fungicidal action, and thus the experiments corroborate the favorable clinical action of these substances. Alcohol, mercurochrome, saturated carbolfuchsin, sodium thiosulphate, ethoxy-diamino-acridine lactate and hexylresorcinol in weak dilution are practically ineffective, and the author thinks that in view of these experimental results the clinical value of the latter group of preparations must be questioned. Resorcinol in a solution of from 1 to 3 per cent proved growth-inhibiting toward *Trichophyton* and fungicidal against *Epidermophyton interdigitale*. Pure benzene and dioxyanthranol were growth-inhibiting for all the fungi tested except *Epidermophyton interdigitale*, but they were fungicidal only for the latter.

Function of Cells and of Colloid in Thyroid—On the basis of his studies, Grab states that the colloid of the thyroid stores the hormone of the thyroid. The hormone probably consists of thyroxine and of acid-soluble iodine fractions. The high concentration of hormone substances in the colloid is characteristic for the normal gland prepared for adequate functioning. The presence in the colloid of considerable amounts of acid-soluble iodine compounds and their secretion into the circulation during increased activity of the gland indicates that these fractions are of great physiologic significance for the function of the thyroid. The epithelial cells have an entirely different function from that of the colloid. These cells have to absorb the iodine-containing substances from the blood, transform and concentrate these substances and store them in the colloid until an adequate stimulus severs their adherence to the colloid and the hormone is secreted into the circulation. These functions apply only to the healthy, normally functioning thyroid and not to pathologic cases, for it has been proved that the great masses of colloid in colloid goiter contain only as much active hormone as a gland of normal size but in a much

lower concentration. The quantity of colloid and its susceptibility to stains are no measure of its functional significance. The author thinks that in pathologic cases the examination of the colloids as the product of cellular action presents a type of functional test of the cells that will point the way in the search for the origin of the pathologic mechanism. It is likely that studies on the quantity of colloid, its actual hormone content and its capacity to store hormone will add considerably to the understanding of the problems of goiter.

Rapid Diagnosis of New Syphilitic Infection—Hoffmann takes smears from the tonsils by scraping them with a sharp curet or with a slightly bent spatula. The fine debris that contains epithelium as well as deeper tissues is crushed between the slide and the cover glass. The addition of physiologic solution of sodium chloride can usually be omitted. As a rule, a definite diagnosis should not be made unless the preparation contains only *Spirochaeta pallida*. However, an experienced person can make the diagnosis also if, besides *Spirochaeta pallida*, other strongly differing spirochetes are present. It is frequently possible to obtain pure preparations of *Spirochaeta pallida* by first wiping the tonsils with diluted alcohol and sodium chloride solution and after that, scraping them with a sharp curet. Before placing the cover glass preparation under the microscope it should be sealed with wax. The examination of the specimen should be repeated one half hour and several hours later, for the microorganisms that at first were covered by detritus may appear later in the spaces only filled with fluid. The same applies also to preparations obtained from primary lesions, papules or lymphatic punctates. The author emphasizes that he has used this method successfully for many years not only in symptomless new cases but also in secondary syphilis with indistinct exanthems. The subsequent serologic tests such as the Meinicke reaction, will generally corroborate the diagnosis, but in rare cases of secondary syphilis in which the seroreaction remains negative the demonstration of the spirochete may prove of great value. In cases in which this simple method is successful the puncture of lymph nodes may be dispensed with. In women and children who have no genital lesion the tonsillar method is especially helpful. If the genitalia show a new primary lesion, material should also be obtained from the cervix or urethra.

Kauffmann's Water Test and Cardiac Function—In testing the reliability of Kauffmann's water test, Zimmermann found that in patients with circulatory disturbances during slight cardiac decompensation the diuresis test is positive almost as often as it is negative, while in a number of patients without clinical signs of cardiac decompensation the test gave positive results. Moreover, the omission of the raising of the feet frequently did not alter the positive result. On the other hand, in persons in whom a negative result had been obtained with a raising of the feet, a subsequent test in which the raising was omitted frequently was positive. On the basis of these and other irregularities in the test the author reaches the conclusion that Kauffmann's diuresis test cannot be relied on as a functional test of the circulation.

Ambulatory Treatment of Flatfoot—On the basis of Bohler's theory that injured or inflamed limbs require complete and uninterrupted immobilization but that at the same

time the muscles should have free play, Schindler treated flatfoot of the muscular contraction type, in which freezing of the peroneus would ordinarily be resorted to, by means of Bohler's plaster-of-paris cast, which permits the patient to walk. He emphasizes that the cast should be as light as possible and that in the first few days circulatory disturbances, pain and inhibition of the movement of the toes should be watched for. The cast is left on for about six weeks, and during this time the patient is free from pain and can walk without difficulty. When the cast is removed, the foot is at once freely movable. That the unpadded plaster-of-paris cast is essential for the use of the member will be realized when it is compared with a padded cast. Apart from the much greater weight of the padded cast, the patient is never entirely free from pain while he wears it. Moreover, Bohler and many who have employed his method have always emphasized that with the unpadded bandage that permits the patient to walk there never develops a stiffening. By using the limb while it is fixed in the cast, the apparently paradoxical result is obtained that the muscles are frequently stronger after removal of the cast than they were before, because in using the member in the cast not only the body weight has to be borne but also the weight of the cast. The author employed the treatment with good results in fourteen cases. He admits that the treatment cannot always do away with more radical interventions, but in a large number of cases it gives satisfactory results without impairment of the working capacity. He thinks that even in flatfoot of the osseous contraction type that occurs in older persons a trial should be given to the ambulatory plaster-of-paris cast. This cast is not always satisfactory in infectious arthritis of the foot but in combination with other methods it may eventually prove effective even in this condition.

Change in Body Posture During Pregnancy—Weltz shows that the change in the position of the center of gravity plays a minor part in the postural changes during pregnancy. In most cases pregnancy is characterized by a stretching of the vertebral column. The decrease in the lumbar lordosis means an enlargement of the abdominal space and the stretching of the thoracic vertebral column serves the enlargement or the preservation of the thoracic volume. If a shifting in the center of gravity were the dominating factor, an aggravation of the lumbar lordosis and of the thoracic kyphosis would be the result. However the author admits certain exceptions to this rule. The aforementioned postural changes apply only to pregnant women who do not have a pendulous abdomen. If the abdominal walls are relaxed so that the abdomen protrudes far there is neither a great pressure on the lumbar spine nor a considerable elevation of the diaphragm. In these cases and only in these the center of gravity is shifted greatly and must be compensated for by a backward placement of the thoracic vertebral column. Consequently there is not a stretching but an increased kyphosis of the thoracic portion of the spine.

Ultrashort Wave Therapy—Schliephake points out that since ultrashort wave therapy aims at treating conservatively conditions that generally require surgical interventions, it deserves especial attention from internists. He reviews animal experiments that prove the selective action of certain wavelengths of the ultrashort type on tumor cells and on certain cells of the central nervous system. His practical therapeutic experiences with the ultrashort waves include 300 cases of furuncles, in which a cure was obtained in an average of about four and a half days. Carbuncles and paronychia likewise were influenced favorably. However, of greater importance is the fact that ultrashort wave therapy is effective in pulmonary abscess, in pleural empyema and in osteomyelitis. In empyemas wavelengths of 6 meters were much more effective than those of from 10 to 15 meters. Parodontitis was effectively treated with wavelengths of less than 6 meters, and granulomas were influenced best by a wavelength of 4 meters. Gynecologic disturbances that yielded to ultrashort wave therapy were pelvi-peritonitis and tumors of the adnexa. Angiospastic conditions were influenced, provided the vascular walls had not yet undergone noticeable changes. This was the case in incipient atherosclerotic gangrene and in angina pectoris. Some cases of migraine also were improved.

Argentaffine Cells of Intestinal Mucous Membrane—Eros and Kunos continue Eros's report of studies on the significance of argentaffine cells in the gastric mucous membrane (first report abstracted in THE JOURNAL, November 11, p 1597). They show that extract from the intestinal mucous membrane of animals that have been treated (left to starve) so as to effect an increase in the argentaffine cells has a therapeutic action on bartonella anemia in rats. The extract inhibits the further development of anemia and promotes hematopoiesis. It was surprising that these results were obtained with extremely small quantities. Larger doses were ineffective or even exerted an inhibiting action on the hematopoiesis. The hemograms of several patients having pernicious anemia were likewise favorably influenced by extracts prepared from the intestinal mucous membrane of starving chickens or hogs.

Extragenital Metastases in Puerperal Sepsis—According to Stefancsik the metastases of puerperal sepsis are of great significance for they indicate a generalization of the infection. He discusses the development of metastases in

various parts of the body. The metastases of the lung and the liver predominated in the cases studied. The author states that in every case in which the diagnosis of puerperal sepsis has been made the patient should be examined daily in order to detect metastases that as yet do not cause complaints. He thinks that, since the complications are frequently fatal care should be given to their prevention, and in this connection he directs attention to the ligation of the veins, a procedure that in recent years has been widely recommended.

Potassium and Calcium in Blood in Dermatitis—Uman-sky and Stepanova call attention to reports in the literature that indicate changes in the electrolyte content of the blood serum in different dermatologic disturbances. There are indications that between the potassium and the calcium ions in the blood there exists a certain relationship that exerts its influence on the skin. The authors report their studies on the potassium and calcium content of the blood of persons having acute eczema and dermatitis. First they determined the normal averages in healthy persons and then they made tests on three patients presenting acute eczema and on two having dermatitis. In each of these patients the potassium and calcium content of the blood were determined once at the height of the pathologic process, again when the weeping of the skin or the edema diminished, either spontaneously or as the result of treatment, and a third time after the complete disappearance of the skin disorder. It was found that, when the dermatitis or the acute eczema with edema are in the severest stage, there is always an increase in the potassium content of the blood and occasionally a decrease in the calcium content. As soon as the edema disappears, the ratio between the potassium and the calcium content of the blood becomes altered in that the potassium decreases and the calcium increases. Following the disappearance of the dermatitis and the acute eczema the potassium and the calcium return to normal.

The Coccyx as an Obstacle to Delivery—Habbe mentions four cases in which he recognized in time that the coccyx was an obstacle to delivery, but he dispensed with the operative removal and instead chose the nonsurgical removal of the obstacle. He fractured the projecting ankylosed coccyx in the course of the extraction by means of the forceps, and he never observed an injury to the child or a tearing of the soft tissues in the mother. In one instance, in which dislocation of the mobilized coccyx took place, the woman suffered from symptoms afterward, but these yielded to treatment. In all other cases, the coccyx healed so that the deviation disappeared. The author thinks that the obstructing coccyx can be removed, eventually, by introducing the hand into the rectum. He advises surgical removal only for cases in which other measures are unsuccessful.

Function of Liver During Pregnancy—Huwer emphasizes that the normal blood status presents a constantly preserved equilibrium between erythropoiesis on the one hand and the physiologic decomposition of the erythrocytes, hemolysis, on the other. He thinks that the study of the various factors involved in the blood exchange will be an aid in the proper estimation of physiologic and pathologic processes of the blood and that it may be helpful in instituting rational therapeutic measures. Studies of the blood of pregnant women convinced the author that the quantity of blood increases toward the end of pregnancy. While in nonpregnant women the blood amounts to 695 per cent of the body weight, it amounts to 786 per

cent at the end of pregnancy. The hemoglobin content in its relation to the body weight is, however, the same, for the increase in the quantity of blood involves only the plasma. Consequently the reduction in the percentage of hemoglobin and in the erythrocyte count, observed during pregnancy, is the result of the increase in plasma, representing a hydrema and only simulating an anemia. The color index remains the same as in nonpregnant women. The blood regeneration is greatly increased during the last weeks of pregnancy, but this increase corresponds to a greater decomposition of hemoglobin, which becomes evident in the elimination of urobilin and of other urinary pigments. The author emphasizes that it is incorrect to estimate the blood decomposition at the end of pregnancy on the basis of the bilirubin concentration of the blood, because the reduction in the albumin content of the blood of pregnant women creates conditions on the basis of which the concentration of the bilirubin is reduced. Studies of the hepatic function of pregnant women convinced the author that a urobilinuria, which could be considered as indicative of an impairment of the hepatic function, does not exist during pregnancy. Moreover, functional tests of the liver, which are based on the elimination capacity of this organ for dyestuffs, are unsuitable during pregnancy, because the albumin reduction of pregnancy has created entirely different conditions. These tests indicate the quantitative vehicle function of the serum protein bodies but not the elimination capacity of the liver.

Ugeskrift for Læger, Copenhagen

95 1183 1206 (Nov.) 1933

*Trichlorethylene Intoxication in Industry K. Roholm—p. 1183

*Clinical Contribution to Trichlorethylene Intoxication T. Christiansen—p. 1187

*Chronic Septic Polyarthrits in Childhood with Eye Complications Two Cases A. Friedländer—p. 1190

Trichlorethylene Intoxication in Industry—Roholm reports four cases of acute trichlorethylene poisoning in Copenhagen factories in December, 1932. He states that other fatal cases have been reported since Stüber in 1931 collected 284 cases of trichlorethylene intoxication with twenty-five deaths. While resorption through the skin is possible, trichlorethylene enters the body mainly through inhalation of the vapors. Besides its narcotic effect, equaling that of chloroform and carbon tetrachloride, trichlorethylene exerts a specific intoxicating action on certain nerves of the brain, particularly the trigeminal. The chemical has an extensive application in industry as a cleanser for metal parts, a dry cleaning agent and a solvent for fats, tars, rubber and so on and is also used in the treatment of trigeminal neuralgia. The author advises that the use of trichlorethylene be restricted so far as possible. It should be heated in tightly closed containers completely cooled before opening, and should not be used in small, poorly ventilated rooms.

Trichlorethylene Intoxication—Christiansen's patient, a woman previously well, developed during the course of two months symptoms suggesting a disturbance of the upper respiratory passages. An accidental result in roentgen examination of the trachea showed an extensive pathologic process in the lungs resembling a miliary tuberculosis. Inhalation of a poisonous gas was denied, but finally it was found that on the day of onset of the symptoms the patient had worked for half an hour, vigorously cleaning a pair of shoes with trichlorethylene. Recovery occurred after about five months. The author states that this case clinically supplements the anatomic pathologic picture of the lungs in the case of trichlorethylene intoxication described by Koch in 1931 and confirms Koch's assertion that trichlorethylene, in addition to its narcotic effect, has properties directly injurious to the lungs and, under certain circumstances, able to cause a lung involvement dominating the picture.

Chronic Polyarthrits in Childhood with Eye Complications—Friedländer calls attention to the fact that an iridocyclitis not only may occur in chronic septic conditions but may also, as in the first case, appear as the initial symptom of a grave general disturbance. The combination of chronic disease of the joints and iridocyclitis in the writer's cases presented such marked points of similarity to tuberculosis that correct diagnosis was not made until a late stage in the disease.

RADIATION IN PRIMARY OPERABLE BREAST CANCER

DOUGLAS QUICK, M B (TOR)
NEW YORK

Until very recently, general acceptance of irradiation in breast cancer has been limited to postoperative therapy and to the palliative care of inoperable, recurrent and metastatic growths. The only contact with the disease in its more favorable stages has been that following operation. It is even questionable whether this has been as altruistic as might seem on the surface. All too frequently the case is referred, following operation, for postoperative irradiation as a gesture and for diplomatic reasons. Unfortunately, the manner in which the postoperative therapy, at times, is given, may justify to some degree this view on the part of the surgeon. In only a limited way has there been a close cooperation between surgery and radiation therapy in the field of breast cancer. While it represents one of the largest groups of cancer, it has not generally received the cooperative effort between surgery and irradiation that has been noted in certain other cancer groups. As far as the operable material has been concerned radiation therapy—when employed at all—has for the most part been started after surgery has been finished.

It would seem that there is now sufficient reliable published information and an accumulation of experience to warrant a reappraisal of the situation. What position does radiation therapy now hold in the treatment of primary operable cancer of the breast? How may it be improved within those limitations? And how may its usefulness be extended? Do the surgical results warrant a complete right of way for operative measures in the technically operable cases? Has radiation therapy enough to offer to justify giving it precedence at any time in this group of cases? Does the accumulated experience with radiation in general warrant taking a bold step into the semidarkness for the benefit of such a desperate disease?

While no such clear-cut definition of controllability by irradiation has been made in breast cancer as with the epidermoid carcinomas, it is my opinion that the accumulated experience is sufficient to warrant advancing of the status of irradiation in the breast group. It deserves initial consideration in the entire primary operable group—not in a competitive but in a cooperative way. It has sufficient to offer to warrant delay in operation for thorough preoperative irradiation. There is neither need nor justification except in certain

special cases for operation the morning after the making of a positive clinical diagnosis. Strictly operable tumors in elderly persons may well be a problem for radiation therapy rather than for surgery. The same may be true for the very young. Advanced growths, still considered operable by many surgeons, will probably do better by irradiation than by surgery.

There is a surprising uniformity in the surgical statistics from large clinics on the three and five year results of surgical treatment alone. The cases without axillary node involvement show a five-year curability of from 70 to 75 per cent. Harrington's¹ series was 71.2 per cent and this may be considered a fair average. This seems at first, most reassuring, yet Portmann reports that 95 per cent of all patients coming to operation have axillary nodes involved. The same author reported from the compilation of a large series of statistics that the average length of life in breast cancer, untreated, is thirty-four months, and that the average curability after operation, in the entire operable group, is 38.6 per cent for the three-year and 28.8 per cent for the five-year period. Sampson Handley² states that 70 per cent of all patients coming to operation have intrathoracic involvement. After a most exhaustive study of the records of patients operated on at Johns Hopkins from 1889 to 1931, Dean Lewis³ concluded that, while the results for the first five years are encouraging, nearly all die of cancer ultimately. He distinguishes between "clinical" cancer and cancer in the "pathologic" sense and urges the most extensive operation possible on the ground of avoiding local recurrence and hence prolonging life in comfort for a longer period. He bases the only possibility of preventing local recurrence on this wide removal, especially of skin.

When the evidence is carefully gone over, the fact remains that of all patients coming to operation at least 70 per cent are dead from extension of the disease at the end of five years and that the majority of the remaining 30 per cent die of cancer ultimately.

With the known and proved value of the physical agents in cancer and in the face of such a gloomy picture from surgery alone, it seems evident that radiation therapy should be pressed more aggressively in the so called operable stages of breast cancer rather than limited to the follow-up phase of therapy.

Unfortunately the relative radiosensitivity between different types of breast cancer is not as well understood or apt to be as clearly defined as in epidermoid

carcinomas, especially those of the mouth and cervix uteri. There are differences between these groups and beyond the histology of the tumor itself. The complex breast structure affords a peculiar tumor bed. The amount of fat tissue in both breast and axilla is of little value in supporting an otherwise normal reaction to irradiation. The mode of dissemination of breast cancer, along multiple paths and through both lymphatics and blood vessels, discounts to some degree the value of local histologic appraisals. The variations between tumor grading and relative radiosensitivity are greater in the breast group than in most of the other major cancer groups. In spite of this, continued study, correlating the microscopic changes with the clinical reaction to irradiation, will go far toward pointing out those groups most amenable to radiation therapy. At present the differentiation rests largely on an anatomic basis—the gross extent of the disease.

In an appraisal of radiation in operable breast cancer, it must be considered (a) in conjunction with surgery and (b) as the sole means of treatment.

SURGERY COMBINED WITH RADIATION THERAPY

From the standpoint of conjunction with surgery, irradiation may be employed as a preliminary to operation, as an adjuvant following operation, or as an accessory aid—castration and total body irradiation—and at the time of operation.

1 *Postoperative Irradiation*—It is in this form that irradiation is most generally accepted and employed. Recognition of its value is unanimous among radiologists and is gradually gaining favor with surgeons otherwise disinterested in radiation. A number of recent and excellent reports by radiologists give statistical proof of the value of this form of therapy. Evans and Leucutia⁴ have reported on the five-year results in a series of 173 cases. Surgery and postoperative irradiation gave freedom from clinical evidence of disease of 76.4 per cent for three years and 70.5 per cent for five years in cases without axillary node involvement. Their comparative surgical results were practically identical, and from this they inferred that postoperative irradiation in this group was probably of no value. The inference is perfectly logical, since the disease was strictly local and the therapy followed operation. Further reference, however, will be made to this point under preoperative irradiation. In their cases with axillary node involvement the curability with surgery and postoperative irradiation was decidedly better over a five-year period than in their surgical group alone. Their group of semiradical operative cases followed by irradiation gave better five-year results than radical operation with no irradiation. This is very interesting, but it is to be hoped that it will not be misleading. It is my opinion that surgery resorted to for direct attack on the disease ought to be as extensive as possible. There are indications for local surgery but under other circumstances, to be discussed later.

Portmann's results with postoperative irradiation give a five-year curability of 43 per cent, a gain of more than 10 per cent over his large compilation of results from surgery alone. It is interesting to note that this improvement in results (10 per cent) is approximately the same as attributed to the improvement in surgical results following Halstead's report in 1894 of the

radical operation, which has since been the pattern for practically all extensive breast surgery.

The extensive and complete report by Pfahler⁵ on more than 1,000 cases in various stages gives the best figures for a combined group, 46.6 per cent of freedom from evidence of disease at the end of five years. He concludes that this is a gain of 90 per cent as compared with surgery alone. The uniformity of these results by independent clinicians is impressive and cannot fail to carry conviction.

There is danger, however, in statistics in the present phase of the development of radiation therapy as far as breast work is concerned. Surgery of the breast has been practically standardized since Halstead's notable publication in 1894, and supplemented by his improvement in adding removal of the pectoralis minor muscle a couple of years later. The procedure has been universally followed and the intervening period of nearly forty years has given excellent opportunity for the collection of most valuable statistics. The review of the entire Johns Hopkins work, including the original work of Halstead, by Dean Lewis is one of the most valuable. Never again will there be a period in which such data will become available from a surgical point of view alone. Irradiation is now complicating this phase of the picture. The period in which all the surgical data have been accumulating is longer than the entire lifetime of radiation therapy. Accurate scientific irradiation is a matter of only a few years and technical improvement is more active now than at any time in the past. It must be remembered that five-year results reported today are the result of work that has become technically obsolete in the interim. The persistent queries of the critics of radiation therapy are not sufficient urge to rush toward premature publication where the results are steadily improving under advancing methods. The careful conscientious observations from day to day and from year to year of the most experienced radiologists are infinitely more valuable. If the opinions of such men are not respected neither will their statistics be respected. Surgical statistics are different. They are backed by time, uniformity of technical procedure and a large volume of material from many sources. As it is, comparable statistics will be difficult to find when the time is ripe for comparison. Too little attention has been given to grouping on the basis of the anatomic extent of the disease. Subdivision of the cases on a gross clinical basis after the plans of Schmitz⁶ or Steinthal is essential if statistical data are to be of real value ultimately.

The practical need among radiologists today, as far as actual postoperative irradiation is concerned, is not a question of the advisability of it, that is accepted. It is on the uniformity of technical procedure, the time to begin it, the intensity and quality of the irradiation and the areas to be covered. I believe that maximum efficiency, within the limitation of postoperative irradiation demands beginning treatment as soon as initial healing has taken place. The shortest wavelengths have proved so far to be the most effective in cancer therapy, and there is no logical reason why the breast should be an exception. The superficial character of the local field and the possibility of serious intrathoracic damage are not logical contraindications. The accessibility of

⁶ Schmitz, Henry. Five Year End Results in Carcinoma of the Breast. *Radiology* 13: 392 (Nov.) 1929.

the local field should be rather a stimulus to greater filter and higher voltages than an excuse for using a less efficient type of irradiation. Finzi⁷ has stated it admirably by suggesting that postoperative irradiation should be quite as aggressive as would be the case were a recurrence actually present. The suggestion of Luff⁸ that radium is preferable for postoperative therapy is undoubtedly due to the fact that the intensity of his radium therapy was much greater than his treatment with x-rays.

The same might well apply to Sampson Handley's preference for radium needles postoperatively, since he admits that he uses very low voltage roentgen therapy. After a radical operation the various and widespread areas that Handley most fears are more accessible to external therapy and better adapted to roentgen irradiation than to radium. Much has been said about intrathoracic damage, and it does occur in certain individuals, whether or not there is a variable sensitivity is questionable. However, many of the reported instances of such damage, if followed for a time, would prove to be extension of the disease. In dealing with a lethal disease, too much caution is more dangerous than an aggressive policy. The skepticism and uncertainty of many German radiologists on the subject of postoperative irradiation is undoubtedly due to inadequate dosage following an overindulgence in massive single doses during the early days of high voltage roentgen therapy.

No blanket rule can govern the areas of greatest intensity in the postoperative cycle. This should be dependent on the observations made by the surgeon at the time of operation and on the location of the primary tumor in the breast. The entire area to be irradiated, however, should be very wide. Dean Lewis has stated that the possibility of reducing local recurrence is dependent alone on the widest possible excision of skin. In my opinion and experience, wide and intensive roentgen irradiation will carry this needed insurance far beyond the borders of the most radical surgical sacrifice of skin, and very effectively. A very pertinent observation has been made by Harrington. He is not in favor of postoperative irradiation as a routine but advises it in cases of high malignancy. This is valuable in that it draws particular attention to the urgent need of extra help in such cases. It one may draw even a partial parallel with certain other tumors in the body, rated as highly malignant on a tumor-grading basis, it might even suggest the probability of accomplishing relatively more in this type, as far as the local and regional areas of possible involvement are concerned. The real danger, however, is from distant involvement, and it at once raises the question of the advisability of preoperative irradiation as an additional safeguard.

As to the time in which postoperative irradiation should be completed, individual operators have many and varied plans. It is the principle rather than minor details that is important. If one may draw on the experience of treating certain growths by irradiation alone, it would seem most logical to consummate the major portion of treatment within a period of from six weeks to three months at most. Sporadic and prolonged irradiation of low intensity is not in keeping with the most favorable general experience in radiation therapy.

2 Preoperative Irradiation—I strongly believe that preoperative irradiation with x-rays of maximum intensity and quality offers more than any other phase of radiation therapy in primary operable breast cancer at the present stage of development of the use of irradiation in this disease. It has encountered much opposition. The majority of radiologists favor it but rarely have an opportunity to practice it. Just why some radiation therapists are opposed is difficult to understand. It is easier to understand why the surgeon opposes it. He is usually unfamiliar with irradiation on the one hand and is bound by the teachings of his preceptors on the other. From a study of the surgical statistics it is obvious that surgery alone has not enough to offer to warrant brushing aside a valuable aid for the sake of operating immediately. The only legitimate excuse for immediate operation is in the case of questionable clinical diagnosis in which frozen sections are necessary as a guide to the extent of operation. One requires only the experience of dealing with various phases of breast cancer by irradiation over a period of years to see the fallacy of Crile's⁹ statement that, in the fortnight necessary for such treatment, cells not completely destroyed would be growing and extending. Total destruction of all cells is not expected, if such were the case operation would be contraindicated. Many cells are completely destroyed. The chief effect, however, is inhibition growth restraint, regressive and degenerative cellular influences on tumor bed as well as tumor cell. The most carefully done operation entails a substantial degree of trauma as a result of which tumor emboli are apt to be dislodged and carried outside the field of operation. A certain number of the 25 per cent of five-year fatalities following operation in the class I cases are undoubtedly due to dissemination at a distance at the time of operation. Postoperative irradiation does not get at these. They are outside the field of postoperative irradiation. Preoperative irradiation of adequate intensity is capable of reducing this type of dissemination. When axillary nodes are involved, it becomes even more valuable in this respect. One needs only to follow a series of these cases to appreciate the advantage of preliminary irradiation. Moran¹⁰ has suggested that one of the theoretical justifications of preoperative irradiation rests on the classic experiments of Murphy of the Rockefeller Institute with irradiated tumor implants and implant beds. The skin will tolerate a minimum of 2400 roentgens over a fortnight, with 200 kilovolts, a filter of 1 mm of copper and 60 cm distance, without serious interference with the surgical procedure. Preferably the operation should be deferred from six to eight weeks, until full effect of the treatment is manifest and most of the inflammatory effect has subsided. On account of the fibrosis, the axillary dissection is slightly more difficult, but healing is not impaired if rigid asepsis is maintained. In some instances, immediate operation following irradiation is called for. The patient's convenience or temperament may influence this. At that stage the operative field is more hyperemic but healing will not be impaired if proper surgical technique is observed, although it is slightly delayed in rate.

Preoperative irradiation means roentgen irradiation. This type of treatment is not amenable to small surface

applications of radium, and radium by implantation is distinctly contraindicated. It is quite a different problem than treatment by radiation alone. The unfavorable comment abroad, especially in Germany, is due to small dosage and to zone irradiation that is too limited. In my experience, tangential irradiation is not practical. It is only in the occasional case that the method can be applied with any degree of satisfaction. Preoperative irradiation has been followed at Radiumhemmet for the past several years and Westermarck¹¹ reporting a small series, finds 40 per cent of all cases classes 1, 2 and 3, free from evidence of disease at the end of five years. The figure is substantially better than similar groups of cases treated by surgery and preoperative radiation only (29.3 per cent). In my own material I have been impressed by the absence of skeletal metastases in the cases that have received preliminary irradiation of maximum intensity consistent with primary surgical healing. It may be a coincidence, a long period of observation alone will be conclusive.

All patients treated preoperatively should, following operation, receive postoperative treatment to the point of maximum skin tolerance. The only possible exceptions to this rule are the class 1 Steintal cases. The point of concentration of this postsurgical irradiation should be dependent chiefly on the anatomic conditions found at operation.

Reports are occasionally made of inoperable breast cancer rendered operable by irradiation. In my judgment, breast cancer once inoperable is always non-surgical as far as the direct treatment of the disease obtains. The more spectacular the regression, usually the more malignant, and hence the more dangerous from a surgical approach. It is at times very tempting to reconsider in favor of operation after a pronounced regression of a tumor primarily judged to be inoperable. The obvious benefit from the irradiation, however, had best be accepted gratefully and added to by the same agent. Indications for operation in such cases are usually not aimed at direct cure of the disease but for other reasons, and are usually local rather than radical procedures. The patient with a very large fat breast may well carry on more comfortably after a local mastectomy, or an area of impending secondary ulceration may to advantage be avoided by the same means.

3 Accessory Irradiation—From time to time the question has been raised of possible added benefit through castration to the patient with breast cancer. Since it is so readily accomplished by irradiation of the ovaries, it is employed by some radiologists as a routine procedure when indicated. From a detailed study of the entire problem, Taylor¹² concluded that the ovarian hormone was a factor of influence. There seems to be no convincing evidence, however, of practical benefit through incorporating ovarian irradiation with preoperative and postoperative irradiation. In a small series of carefully observed cases at Radiumhemmet Ahlbom¹³ was unable to find evidence that would support the theory in a practical manner.

4 Irradiation at Time of Operation—In certain instances, radium by implantation, preferably radon in gold seeds, may be used to advantage, depending on

the anatomic observations. Reference is made to the posterior portion of the axilla and to the upper intercostal spaces adjacent to the sternum, to which Sampson Handley has so frequently referred.

Before any extensive program of irradiation or surgery in operable breast cancer is assumed, a meticulously careful radiodiagnostic check up should be made of the chest and skeleton. It is a safeguard against grief and embarrassment in a few cases. The chief value lies in an early and permanent record for subsequent comparisons which symptoms may call for.

RADIATION AS THE SOLE MEANS OF TREATMENT

Experience is gradually accumulating on this vital and fascinating phase of mammary cancer therapy. Opinion will differ sharply as to whether the advising of such a procedure freely, in operable breast cancer, at the present time represents courage or foolhardiness. The conscience of the seasoned radiologist or cancer surgeon must be his guide. There may be a very nice distinction at this stage of the development of work between the responsibility one may assume under circumstances of strong personal pressure and the routine of professional work. At least there is a wealth of experience with all types of radiation and in all phases of the advanced disease as a background. There are a good many technically operable cases in which successful treatment over a period of years has been carried on. For one reason or another—age, general constitutional conditions or abnormal aversion to surgery—the radical operation has been withheld and irradiation substituted. On this basis alone, a substantial amount of material will be accumulated within a few years. To date, much of such material is of value only to those actually participating in the care of the individual case. Few biopsies have been obtained.

My first primary operable breast cancer treated by irradiation only, and now well over fourteen years ago, fails to be of value or conclusive to other than the three experienced cancer clinicians who concurred in the original clinical diagnosis, for just this reason. A woman, aged 49, had a tumor in the upper outer quadrant of the breast which was steadily progressing in size up to 2.5 to 3.5 cm. diameter, and over a known period of three months. There was a questionable node palpable low in the axilla. However, the case is best rated as Steintal, class 1. For esthetic reasons—the patient was a concert singer—she was strongly opposed to surgery and knowing something of radiation pressed for treatment by the physical agents. She finally offered to assume her own future risk if I would but agree to this course. I treated her with the 1919 type of low voltage roentgen radiation and followed it by implantation of unfiltered radon into the tumor and the under surface of the free border of the pectoralis major muscle. The tumor regressed rapidly at first and then more slowly. After three years there was a dense residual mass in the breast and telangiectasis of the overlying skin, such as was common with that quality of roentgen radiation. There has been no noticeable change since.

Only a biopsy is necessary to make even one such case of that duration a matter of valuable record. Various authors, Moran and Wintz particularly, have pointed out that a biopsy is safe if deferred until a fortnight after irradiation has been initiated. By careful handling of tissues and through a small incision placed as obscurely as possible, information may safely be obtained. The value as a future guide in therapy

¹¹ Westermarck, N. Result of the Combined Surgical and Radiologic Treatment of Cancer Mammæ at Radiumhemmet 1921-1923. *Acta radiol.* 11: 1, 1930.

¹² Taylor, H. C. Jr. The Etiology of Neoplasms of the Breast. *Arch. Surg.* 21: 412 (Sept.), 597 (Oct.) 1930.

¹³ Ahlbom, Hugo. Castration by Roentgen Rays as an Auxiliary Treatment in the Radiotherapy of Cancer Mammæ at Radiumhemmet. *Acta radiol.* 11: 614, 1930.

adequately compensates the patient for the slight inconvenience, and it is invaluable to the future record. The theoretical objections to a biopsy are far outweighed by the practical information obtained. A tissue section represents the central point of the data-complex on which relative radiosensitivity is based and on this in turn better radiation therapy is dependent. A biopsy by needle puncture under negative pressure is unsuitable for breast diagnosis except as a last resort.

Any attempt at this time to define the types of operable breast cancer which might justifiably be turned to irradiation entirely resolves itself into an expression of personal preference by the individual author. Certainly there should be little question about those suffering from a grave constitutional disease as well as the elderly and the very young. Elderly patients are prone to carry on for many years without treatment. In very young subjects, surgical results are so discouraging that any benefit from irradiation might well be considered a gain. Furthermore, the esthetic side in these patients lends strong support to the conservative method. In my opinion, cases with a long history of recognized tumor prior to seeking treatment should be considered poor surgical risks even though the local conditions place them in the operable class. Irradiation instead might well be considered acceptable. This is equally true of cases of the advanced Steinthal class 2 group—those with extensive palpable node involvement.

One cannot help but admire the bold position taken by Geoffrey Keynes¹⁴ and some of his associates in London. Since the London Cancer Conference of 1928, a number of English radiologists have become ultra-radium minded. It is questionable whether or not good judgment from a physical standpoint has kept pace with their bold stand on radium for breast cancer. At any rate, they seemingly stress the value of radium without giving quite as serious consideration to roentgen irradiation. It is a matter of individual opinion as to whether or not their recommendation of radium as the sole treatment for most operable breast cancers is premature. Keynes introduces radium needles, and for several days exposure, on two occasions on each patient, each introduction being made under general anesthesia. Handley disagrees with the claimed uniformity of the distribution of radiant energy by his technic. Fitzwilliams¹⁵ agrees with the Keynes technic and is seemingly more radical than the latter in his assignment of material to this method of treatment. Cade¹⁶ endorses it but places added stress on surface applications of prolonged duration. The obvious factor of trauma incident to two introductions of many large radium needles and each set must in turn be removed, is not in keeping with the generally accepted view of trauma in a tumor-bearing area. Mr. Souttar¹⁷ has obviated this in large measure in his cases by using permanent gold-filtered radon implants. The two anesthetics give the impression of a major surgical procedure. In my own experience, external irradiation with x-rays in intensity going far beyond that previously outlined for preoperative therapy, in multiple divided doses and of the shortest available

wavelength will afford complete local control of many breast tumors. A few cases extend now to six and seven years. In some instances the intensity requires implantation following the external irradiation, and for this radon in 0.3 mm wall-thickness gold seeds is used. Radium for external irradiation in quantities sufficient to parallel the present-day roentgen radiation, is neither economic nor practical.

Even though responsibility for the breast cancer in certain instances is placed on irradiation, a subsequent need for surgery occurs at times. In the very large pendulous fat breast, granting "sterilization" of the growth by irradiation, a simple mastectomy may render the patient much more comfortable. I cannot agree with Finzi that removal should be done as a routine after the tumor is "cured" by irradiation. There may well be justification for this position, however, in the scirrhus type of tumor, on account of its radio-resistance and danger of subsequent reactivity. Secondary necrosis rarely occurs, but when it does, or preferably when it is threatened, local mastectomy is indicated for comfort and for the peace of mind of the patient. It is impossible to eliminate all surgery from any one group of cancers of the breast. Finally, while irradiation alone seems amply justified, in fact preferable, in certain groups of primary operable breast cancer, it also seems decidedly premature to regard it as the method of choice in the majority of cases. This is especially true in view of the marked improvement in results through combining preoperative and postoperative irradiation with the radical operation.

In attempting to make an appraisal of the probable value of irradiation in a given case, many factors must be considered. The histologic character of the growth is important and with added experience will become much more so. The size and location of the primary tumor in the breast, its known duration, presence or absence of axillary nodes, its location and extent are all important in selecting and directing the local irradiation. The age of the patient and the rate of growth are of value in governing the intensity of treatment. The general physical condition of the patient and the presence or absence of secondary anemia have substantial bearing on the probable manner in which irradiation will be tolerated and on the reaction to it.

Whatever agent, method or combination of x-rays and radium, with or without surgery, is decided on, no fixed routine plan is desirable. Adherence to fixed principles of therapy, rather than to fixed technical details, is the important factor. The factors of influence just previously mentioned must be correlated with what is expected to be accomplished by the irradiation.

THE RELATIVE VALUE OF X-RAYS AND RADIUM

In early breast cancer there seems little room for doubt that roentgen radiation occupies the major position. Most of the treatment is by external application and over wide areas, for this, x-rays are technically best adapted and most economic. Radium occupies a limited but valuable place, and always for implantation. Occasionally a primary tumor assigned wholly to irradiation requires implantation, and at operation radium by implantation may frequently be used to advantage in the axilla or the upper intercostal spaces adjacent to the sternum. For these purposes radon in gold seeds affords a wide range of flexibility in application and is much less damaging from the standpoint of

14 Keynes, Geoffrey. The Treatment of Primary Carcinoma of the Breast with Radium. *Lancet* 10: 393 (1929). Treatment of Primary Carcinoma of the Breast with Radium. *Practitioner* 125: 462 (Oct.) 1930. Radium Treatment of Carcinoma of the Breast. *Lancet* 1: 439 (March) 1930.

15 Fitzwilliams, D. C. 1. The Modern Treatment of Carcinoma of the Breast. *Practitioner* 127: 483 (Oct.) 1930.

16 Cade, Stanford. Cancer of the Breast. *Practitioner* 125: 469 (Oct.) 1930.

17 Souttar, H. S. Treatment of Carcinoma of the Breast by Radium Implantation. *Brit. M. J.* 1: 513 (May 13) 1931.

trauma Radium or radon implantation should always follow rather than precede the roentgen irradiation. Whatever the combination, and with few exceptions, the intensity of irradiation should be the maximum consistent with the tolerance of normal tissues within the zone of irradiation, and the quality always of the shortest wavelength available from up-to-date equipment. There is a limited time interval within which both the tumor and the tumor bed react most favorably to any type of irradiation, and improvement in results demands that advantage be taken of this. Meticulous attention to detail is quite as essential to success in radiation therapy as in surgery. As Moran has so aptly stated, 'the careless radio-therapist, like the rough-handed surgeon, may cause grave mischief.'

SUMMARY

1 Heretofore, irradiation has been limited almost entirely to postoperative treatment. Reference is made to primary operable breast cancer exclusively.

2 Postoperative irradiation has improved the five-year curability results.

3 The experience to date warrants advancing the status of radiation therapy in this group of cancer.

4 Preoperative irradiation is probably of greater relative value than postoperative.

5 In all cases of radical mastectomy, preoperative and postoperative irradiation should be employed.

6 While the ovarian hormone evidently exerts an influence on the development of some breast cancers, there is no substantial evidence to warrant castration by irradiation as a therapeutic aid.

7 As the sole means of treatment, irradiation is justifiable and undoubtedly preferable in certain cases.

8 To consider irradiation alone the method of choice in all cases of this group is premature.

9 Cases treated by radiation alone require biopsy not only for guidance in therapy but also to complete the record.

10 Biopsy is safe if carefully done after preliminary irradiation.

11 Of various methods of irradiation, preference has been given to x-rays for external therapy over wide areas and to gold seeds of radon for implantation.

12 X-rays occupy by far the major position in the radiation therapy of this group.

13 The same degree of attention should be given to technical detail in radiation therapy as in surgery.

350 Park Avenue

ABSTRACT OF DISCUSSION

DR FRED O'BRIEN, Boston. The report on irradiation of breast cancer which appeared in 1930 under the auspices of the American College of Surgeons, practically put an end to radiation therapy of the breast in my particular hospital for about two years because it was carelessly read and carelessly interpreted. Although Greenough stated that he was reporting statistics based on procedures of the decade 1910 to 1920 and that the data on irradiation were insufficient to form a basis on which to draw conclusions, I agree with Dr Quick that the Halsted operation should be the standard operation but it is far from being accepted by surgeons in general. There has been criticism of radiation therapy in the past because of the variety of methods employed, yet roentgen therapy has been in flux from the very nature of the thing, while the operation of Halstead has been known since 1894. There appeared a review in THE JOURNAL of operative procedures on the breast as practiced throughout the United States. It was found that only about 50 per cent of the surgeons employed the complete

operation. It was most injudicious to be dogmatic about post-operative irradiation under those circumstances. I think that better results may be expected from clinics in which the surgical and the roentgen therapy methods are uniform. I think that Dr Quick is correct when he says that it does not make any difference whether the patient is operated on the next day after the tumor mass has been found or two weeks from that time. These cases should be handled through a tumor clinic, so that patients will not get into the hospital before they have had their preoperative irradiation. Dr Quick spoke about the time for postoperative treatment and said something about waiting for healing. My own feeling is very definite that irradiation does not retard healing, in fact, I know that it helps in the healing of many wounds. I have always thought that preoperative irradiation was most logical. If it is good afterward it ought to be equally good, if not better, before. I have seen no skin damage in recent years. Lord Moynihan stated in New York a few years ago that surgery had had its chance and had accomplished nothing and that he believed that now irradiation should be given its chance.

DR U. V. PORTMAN, Cleveland. Dr Quick has asked me to speak about the percentage of axillary involvement in my report of several years ago, which was based on statistics given by pathologists. I think the figure of 95 per cent of axillary involvement is probably a little too high and that it should be about 85 per cent. In other words, about 15 per cent of cases do not present axillary node involvement. This paper is not given with the idea of eliminating the surgical treatment of cancer of the breast but with the idea of proper treatment according to indications. With Dr Quick, I think that as radiologists we should insist on some classification based on clinical rather than microscopic observations. It is my experience that I can tell more about what the subsequent course will be from the clinical story than I can from what the pathologist tells me. When a scirrhous type of growth is present an entirely different clinical problem is presented than when more rapidly growing tumors are concerned. A tumor of long duration cannot be affected much by radiation and operation is preferable. Perhaps Dr Quick will agree with me that the less clinically malignant the less radiosensitive the tumor will be. I certainly agree with Dr Quick that a primarily inoperable case never becomes operable. This applies not only to breast carcinoma but also to malignant neoplasms in any other place in the body. As Dr Quick has prophesied, more cases of cancer of the breast will be turned over to the radiologist. But it is unfortunate that only about 15 per cent of all these patients have no axillary nodes involved and these are ideal for irradiation. As the skin becomes infiltrated by the neoplasm, the surgeon has a difficult task and I suppose that no surgeon will say that he can remove all the axillary involvement in 50 per cent of his cases. It has been my experience that a great many of them do not excise widely enough. It is in the operable cases that irradiation should be most valuable. In a great many the tumor itself can easily be eliminated by interstitial irradiation, and external irradiation will often destroy the skin extension.

DR DOUGLAS QUICK, New York. I want to stress the need among radiologists to group these cases on some practical basis. While various means have been suggested I lean toward the clinical and anatomic basis, because it is simple and permits of drawing rather straight lines. The group I cases are those strictly primary breast tumors without palpable nodes. The second class includes those with palpable, technically operable, nodes and the third class, those with fixation of the primary tumor or with distant involvement. A good deal of knowledge on the relative radiosensitivity of these tumors is being acquired but it is not comparable with existing knowledge of radiosensitivity in certain other groups. Consequently it cannot be leaned as heavily on as a guide at the present time but I think that a point will be reached where, from a histologic standpoint, one can pick out more definitely the types best suited to irradiation. I should like to stress the encroachment if one chooses to call it that of the radiologist on the breast cancer field. It represents a cooperative and not a competitive effort in any sense.

GASTRIC ACIDITY IN THYROID
DYSFUNCTIONS ALLEN WILKINSON, JR., MD
BOSTON

It has been recognized for some time that hyperthyroidism causes changes in gastric acidity and that in some cases there is an absence of hydrochloric acid. Hardt¹ in 1916 called attention to the fact that thyroid feeding caused lowered gastric acidity in normal dogs. Barker² in 1918 mentioned hypochlorhydria, and King³ in 1919 noted that achlorhydria and achylia occur in hyperthyroidism. Lockwood⁴ in 1925 and Moll and Scott⁵ in 1927 reported a high incidence of achlorhydria in exophthalmic goiter. Following this line of thought, Truesdell⁶ in 1926 showed that a lowering of acidity could be produced regularly by feeding thyroid to dogs, and in some achlorhydria was produced.

On the other hand, Crile⁷ and his co-workers have held that the same mechanism that produced hyperthyroidism could in some cases produce peptic ulcer. He has also stated that denervation of the suprarenals and a hemithyroidectomy frequently relieves recurrent peptic ulcer. If this theory is true, hyperthyroidism should raise, not lower, the gastric acidity. Lerman and Means⁸ have shown, however, that there is a definite tendency to lowered gastric acidity in hyperthyroidism and that the proportion of achlorhydria is increased beyond the normal.

This study was undertaken to show the relationship between hyperthyroidism and gastric acidity and to determine to what extent the acid returned to its normal level after relief of the toxicity. Also, we wanted to see what effect a postoperative lowering of the basal metabolic rate below the normal level would have on gastric acid.

This study comprises the results of gastric analyses in 100 cases of hyperthyroidism, taken before operation. At the Lahey Clinic it is the practice to have all patients return three months after partial thyroidectomy for a check-up metabolism. Of the original 100 cases we were able to get only about one half back for check-up gastric studies. This was due partly to the reluctance of some patients to have a second test, partly to inability to return, and partly to the fact that three months has not elapsed since some of the original tests were made. It was felt, however, that for purposes of averages, a comparable number of postoperative check-ups would give as much information. Consequently, determinations were made in 114 cases. In addition,

there was a much smaller group of patients with spontaneous myxedema who had had no operative history. Determinations were made in as many of these as possible, but cases of true myxedema are rare. Hursthal⁹ has shown that, in order to be classified as true spontaneous myxedema, the patient should first present the clinical signs and symptoms of the disease, secondly he should have a low metabolism and lastly he should have an elevated blood cholesterol. Many patients have a low metabolism but they do not fulfil the other two criteria and are not benefited by thyroid medication.

The method of gastric analysis used in this series was the same in all cases. A test meal of 50 cc of 7 per cent alcohol was given on a fasting stomach after all the residual stomach contents had first been aspirated. Five minutes later a subcutaneous injection of histamine acid phosphate was given. The dose used was 0.1 mg of histamine for each 10 Kg of body weight. Fractional samples of the gastric contents were taken at thirty, sixty and ninety minutes. While it is usually customary to aspirate at fifteen-minute intervals and for a two-hour period, a short preliminary series indicated that, for all practical purposes, this test was just as accurate and much simpler. In no case in this series was acid obtained at the one and one-half hour extraction when it had been absent in all the previous extractions. The averages in this series were obtained

TABLE 1—Hyperthyroidism Averages Before Operation

Metabolism	Cases	Basal Metabolic Rate	Free Acid	Total Acid	Variations in Acidity	
					Free Acid	Total Acid
Over +35 with acid	40	+52	34.7	46.8	3-60	6-92
Under +35 with acid	24	+20	42.7	54.7	6-6	12-62
Over +35 without acid	0	+52	0	14.8	0	4-30
Under +35 without acid	6	+25	0	15.0	0	10-20
Averages all cases	100	+42.6	24.0	36.9		

from the maximum free and total acid values obtained during the course of each test.

There is considerable divergence of opinion as to what constitutes the normal level of acidity. For my purposes in this paper the normal level is irrelevant, as the figures quoted are on a comparative basis rather than a fixed standard. Vanzant and others¹⁰ have reported a large series with the standard Ewald meal and a single one-hour extraction. Histamine was not used as a routine in their series. They give the average figure for free acid at 40 and the total acid at 57. Lerman, Pierce and Brogan,¹¹ using an alcohol test meal and histamine, report the normal free hydrochloric acid as 40.4 and the total acid as 50.1.

In table 1 are the averages of 100 cases of toxic goiter, of these, 91 cases were primary hyperthyroidism and 9 were adenomatous goiter with secondary hyperthyroidism. Thirty-six patients had achlorhydria. In the group with free acid are included about ten patients who had a very low acid (under 10). As the table indicates a large proportion of those who had achlorhydria fell in the group who had a basal metabolic rate higher than +35.

Table 2 shows the averages three months or more after operation in 114 cases. In this group twelve, or 10.5 per cent, showed no acid, while 102 or 89.5 per cent, showed free acid. The level of acidity has risen in the whole group as well as in the cases in which there was free acid. The average free acid was 46, as compared with 24 in the group before operation. The highest level of free acidity before operation was 427 in the group with a basal metabolic rate of less than +35, whereas in this postoperative group with free acid the average is 51.2.

Table 3 shows the results after operation in twenty-five of the original thirty-six patients who had no acid before operation. These check-up tests were all made about three months after partial thyroidectomy. In this group only three still showed achlorhydria, while twenty-two had regained their acid.

In table 4 are those cases presenting low metabolic rates. There were only five cases of spontaneous myxedema. One of these patients had been taking thyroid for two years, and it is interesting that she had achlorhydria. Of the other four who had never had thyroid, the minimum free acid was 83 and the maximum was 98. One of these patients was later found to have a duodenal ulcer. In the postoperative hypothyroid group, none of whom had the clinical signs of myxedema, the average acidity is also very high. I realize that this series is too small to justify any general conclusions, but it shows an interesting trend.

achlorhydric group showed an average duration of 166 months, and only two cases in this group had had symptoms less than six months. It seems, therefore, that the development of achlorhydria depends on the duration rather than on the degree of toxicity.

Of more interest than the actual development of the achlorhydria is the fact that these patients recover their acid so promptly. Three months after relief of the toxicity, 89.5 per cent have recovered their normal gastric acid, and this recovery takes place as well in the anacid group as in the group with free acid. The rise of acid must take place fairly promptly, and appar-

ently it returns to the normal level and even passes this level. We have no figures to show whether it later falls again.

There have been theories as to whether the depression of gastric acid was a result of actual damage to the gastric mucosa or the result of some constitutional cause. Our observations do not indicate any damage to the gastric mucosa and point to a depression of glandular function. It is well recognized that most of the symptoms of hyperthyroidism are those of extreme overstimulation of the sympathetic system. It is also recognized that, when the sympathetic nervous system is stimulated, the autonomic system is correspondingly depressed. Might not this change in gastric acidity be an expression of the same mechanism that produces the warm skin, the perspiration, the tremor and general activation? Moll and Flint¹³ have touched on this and point out that both in man and in animals, epinephrine in sufficient doses over a considerable period of time will markedly depress gastric secretion and gastric acidity. They also point out that nicotine, which

ACHLORHYDRIA

Our figures agree quite accurately with those of Lerman and Means⁸ with respect to lowering of acidity in toxic goiter. Their series of fifty cases shows 38 per cent of achlorhydria as compared with the figure of 13 per cent according to the observations made by Lerman, Pierce and Brogan¹¹ in a series of 200 normal persons. The latter figure of 13 per cent is much higher than that quoted by Bockus, Bank and Willard,¹² which was 5.7 per cent, but these last investigators used a bread and water test meal with histamine instead of an alcohol test meal. We are in agreement with Lerman and Means who state that the achlorhydria cannot be accounted for on the basis of a general lowering of acidity. The average level of acidity is about one-half the normal while the incidence of achlorhydria is increased at least four times.

While it is true that the majority of the cases of achlorhydria fall in the high metabolism group above +35, this does not, in itself, seem sufficient to account for the figures obtained, as in the same group there were forty cases that showed an average free acidity of 34.7. In searching for a better explanation, we investigated the duration of symptoms of toxicity and found that, whereas the group with free acid showed an average duration of 9.2 months and 68 per cent of this group an average duration of only 3.8 months the

TABLE 4—Low Metabolic Rates Averages

	Cases	Basal Metabolic Rate	Free Acid	Total Acid	Before Operation	
					Free	Total
True myxedema	5	-24	67.5	81		
Postoperative hypothyroidism	4	-23	81.9	94	22	37

depresses sympathetic nerve endings, produces hyperchlorhydria.

MYXEDEMA

The evidence presented in the literature concerning gastric acidity in hypothyroidism is conflicting. Katz,¹⁴ Levy¹⁵ and Hutton¹⁶ concur in stating that low thyroid function produces hyperchlorhydria. On the other

16 Hutton J H. Effects of Hypothyroidism. *Illinois M J* 42: 347 (Nov.) 1922.

J. Lockwood⁴ found achlorhydria in 60 per cent of cases of myxedema. Lerman and Means⁸ found cases of achlorhydria in seventeen cases of hypothyroidism. Our series is too small to be of much light but such evidence as we have points toward a definitely increased acidity in these cases. In those patients who conformed to the criteria for myxedema, free acid was 67.5 and the total acid 81. In the operative low metabolism group the acidity was higher. One of these patients had achlorhydria before operation.

SUMMARY

Of 100 cases of hyperthyroidism, 36 per cent showed achlorhydria, and the average acid of all cases reduced to slightly more than half the normal.

The observation is made that the incidence of achlorhydria in hyperthyroidism rises in proportion to duration of the toxicity rather than the degree of toxicity.

After thyroidectomy, only 10.5 per cent show achlorhydria. The average free acid is raised to about normal value for the entire series.

A theory is offered that the depression of gastric acidity is a phenomenon of extreme sympathetic over-irritation.

Hypothyroidism in our series at least, produces a definite tendency to hyperacidity.

15 Commonwealth Avenue

ABSTRACT OF DISCUSSION

DR RALPH C. BROWN, Chicago. The point of chief interest in Dr. Wilkinson's study is the evidence showing a return of normal physiologic activity in the gastric secretory glands after cessation of hyperthyroidism following thyroidectomy. This evidence supplies what would seem to be a convincing proof of the influence of thyrotoxicosis in suppressing gastric secretion. The fact that all but three of the twenty-five rechecked cases which had been achlorhydric under histamine prior to thyroidectomy regained an average free hydrochloric acid of 44 after recovery from thyrotoxicosis is of evident importance. It emphasizes the need for caution in assuming that a gastric secretory mechanism which fails to respond to histamine is likely to be permanently disabled. The presence or absence of fermentations is a much more reliable basis for a prognosis regarding possible future secretory activity. A review of twenty cases of hyperthyroidism and ten cases of myxedema treated at the Presbyterian Hospital in which gastric secretion studies were made a standard Ewald meal without histamine using undiluted yielded figures somewhat at variance with those reported. In nineteen cases of moderately severe and severe hyperthyroidism with basal metabolic rates ranging from plus 36 to plus 82 I found only three cases of achlorhydria, 16 per cent, a figure only 3 per cent higher than the incidence of achlorhydria in otherwise normal individuals. There were five cases in the subacid group (free hydrochloric acid 20 to 40) nine cases presenting normal acid values (free hydrochloric acid 21 to 40) and two cases of hyperchlorhydria (free hydrochloric acid 41 plus). The average basal metabolic rate in this group of nineteen cases was plus 48. The average duration of symptoms of thyrotoxicosis was fourteen months. The less severe group of thirteen cases with rates ranging from plus 26 to plus 35 only one case of achlorhydria was found and six of these cases presenting a normal acidity and six definite hyperacidity. Combining these figures, one has thirty cases of hyperthyroidism in which only four, or 13 per cent, presented achlorhydria. The average metabolic rate for the entire group was plus 41. The average acidity was 32 units of free hydrochloric acid and the average duration of symptoms was 16.8 months. It may be worth noting that in a larger series thirty-nine cases of mild but (according to my point of view) definite cases of hyperthyroidism showing rates ranging from plus 16 to plus 25 I found four achlor-

hydrias with only five subnormals, nineteen cases, or 50 per cent of the group, showed normal gastric secretion, and eleven cases, hyperchlorhydria. The average duration of symptoms was twenty months. Regarding hydrochloric acid values in myxedema. In ten cases in which the basal metabolic rates ranged from minus 22 to minus 47, and an average of minus 32.6, two were anacid, four were subacid, three gave normal hydrochloric acid values and only one showed a hyperacidity. Again, the number of cases is small, but the observations certainly do not suggest a tendency to hyperchlorhydria in myxedema. Lerman and Means found nine cases of achlorhydria in seventeen cases of myxedema. I should like to ask Dr. Wilkinson whether evidence of any marked lowering of pepsin and rennin secretion was observed in these cases during the achlorhydric phase, also whether any observations were made indicating any greater incidence of gastro-intestinal symptoms, especially diarrhea, in the achlorhydric group of cases than in the cases of acid secretion.

DR S. ALLEN WILKINSON, JR., Boston. I am indebted to Dr. Brown for his discussion. I do not know how to explain the divergence in figures he has quoted as compared with mine. It is true that in my first twenty cases I failed to find any unusual incidence of achlorhydria. I have no idea why this happened. With regard to changes in gastric ferment, I did tests for gastric rennin in ten cases of this series who showed achlorhydria. Rennin was present in all of the ten cases, and there were none which I could call achylia gastrica.

METABOLIC ACTIONS OF DINITROPHENOL

WITH THE USE OF BALANCED AND
UNBALANCED DIETS

W. C. CUTTING, MD

AND

M. L. TAINTER, MD

SAN FRANCISCO

Dinitrophenol (1-2-4) has been shown to increase promptly the metabolic rate in man and laboratory animals to almost any desired level. This action is peripheral, in the tissues, and independent of nervous and glandular functions. Small doses cause a slight increase in oxygen consumption, larger doses cause heat production that may surpass the ability of the animal to dissipate it, so that death occurs from heat rigor.¹ We have suggested that, in proper dosage, dinitrophenol would be a potent therapeutic agent in obesity and in conditions in which a heightened metabolism might be desired. In a consideration of such possible uses the question arose of the source of the fuel for the increased metabolism. That is, dinitrophenol might promote the burning of carbohydrate, fat or protein, or all these fuels equally readily. A selective action on some one fuel appeared unlikely. An attempt was made, therefore to study this question for human metabolism, experimental diets applicable to clinical conditions being used. The results are reported in this paper. Briefly, the results show that during medication with dinitrophenol the human body can maintain nor-

mal nitrogen and acid-base balances while reacting with the usual increase in metabolism, regardless of the type of food consumed and without undesirable symptoms

METHODS

Eight experiments were made on four subjects with four different diets, each diet being taken by two different individuals. In each experiment a subject was placed on a given diet for two weeks or longer, and his body weight, basal metabolism, nitrogen balance and urinary organic acids were determined at regular intervals. The first week served as a control period without medication. Immediately following, during the second week, occurred the experimental period with dinitrophenol. The diets in all cases contained 40 calories per kilogram of body weight, a value considered to be adequate for subjects leading a sedentary life and possessing a normal metabolic rate. The diets were all carefully prepared and controlled in the special diet

van Slyke.³ The values are expressed as cubic centimeters of tenth normal hydrochloric acid, required for the neutralization of the urine in twenty-four hours. It was assumed that, if the acid-base balance was disturbed or if acetone bodies were excreted, the organic acid figure would be increased. The dinitrophenol was administered in capsules as a single daily dose by mouth and before breakfast.

REGULAR DIET

In the first experiment, the subjects were placed on diets containing 1 Gm of protein per kilogram of body weight with the carbohydrate and fat apportioned about equally as to caloric value. This constituted an essentially normal balanced diet. For subject M O, who weighed 74 Kg, the diet contained 2,960 calories and was made up of 308 Gm of carbohydrate, 74 Gm of protein and 150 Gm of fat. The diet for subject R U, who weighed 63 Kg, contained 2,520 calories and was made up of 263 Gm of carbohydrate, 63 Gm of protein and 142 Gm of fat. After a week of control observations, the first subject was given 225 mg of dinitrophenol daily for eleven days, followed by 300 mg daily for five more days. The second subject was given 225 mg daily for seven days. The results obtained are presented in the accompanying chart.

The metabolism in M O rose from an average control of -10 per cent to +30 per cent, or a rise of 40 per cent, by the ninth day of medication with dinitrophenol and remained at this level for the next seven days. In R U the metabolism rose from a control of +5 per cent to +45 per cent, or a rise of 40 per cent, by the sixth day of medication with dinitrophenol and remained at this level for the next two days.

In M O, the daily nitrogen intake was 118 Gm and the output varied from 11 to 14 Gm, with an average of approximately 128 Gm throughout both the control and the experimental period. The daily nitrogen intake for R U was 101 Gm, and the output varied from 8 to 11 Gm with an average of 10 Gm throughout both periods. Therefore the dinitrophenol produced no significant changes in nitrogen balance. The organic acids in the urine were constant at

about 800 cc throughout for M O and fell from an average of 1,500 to 750 cc in R U during the action of dinitrophenol. Therefore there was no increase in acid bodies in the urine following administration of the drug.

M O lost 2 pounds (0.9 Kg) during the control period and about 1 pound (0.45 Kg) during the dinitrophenol period. R U lost weight similarly. With so short a period of medication with dinitrophenol as one week, the weight changes are not striking. A loss of weight might be expected unless the caloric intake was adequate to provide for the increased metabolism. This would not have been the case if the control diets had been just adequate for maintenance at normal metabolic levels, as planned. However, since the water intake and the activity of the subject were not controlled, it is possible that considerable changes in the daily weights might occur from these factors. The

Effects of the administration of dinitrophenol on human subjects on balanced and unbalanced diets: composition of the diets for each subject; metabolic rate; total daily nitrogen intake and output; total daily urinary organic acids; changes in body weight; and dosage of dinitrophenol.

laboratory of the Stanford hospitals. Fluids were not limited. Each subject was weighed daily at the same hour. Nitrogen intake was calculated from protein intake, 6.25 Gm of protein being used as the equivalent of 1 Gm of nitrogen.

The metabolism was determined under basal conditions early in the morning, three times a week. No food or fluids were taken for at least twelve hours before the metabolic test, and there was a rest in bed of half an hour immediately preceding it. Twenty-four hour specimens of urine were collected daily and analyzed for urinary nitrogen by the macro-Kjeldahl method. To the value for urinary nitrogen output there was added an arbitrary value of 1.3 Gm as an average value for daily nitrogen in the feces.³ The values for nitrogen output throughout this paper are the sum of these two quantities. The organic acids in the urine were estimated by the titration method of

³ Peters, J. P. and van Slyke, D. D. Quantitative Clinical Chemistry. Baltimore: Williams & Wilkins, 1929.

⁴ Van Slyke, D. D. and Palmer, W. W. J. Biol. Chem. 41: 567 (April) 1920.

subjects continued their normal activity during the medication with dinitrophenol, and the only symptoms noted were a feeling of warmth and a tendency to perspire freely

It may be concluded from the results of experiments on two normal subjects on a normal balanced diet that a 40 per cent increase in metabolism caused by dinitrophenol did not significantly modify the nitrogen or acid-base balance or cause unpleasant symptoms

HIGH CARBOHYDRATE DIET

In the second experiment, the carbohydrate of the diet was increased to the limit of palatability while the basal protein need of 1 Gm per kilogram and the total caloric intake were left unchanged. This resulted in a reduction of the dietary fat to a minimum. For M O, who weighed 74 Kg, this diet contained 2,960 calories and was made up of 533 Gm of carbohydrate, 74 Gm of protein and 50 Gm of fat. For P O, who weighed 61 Kg, the diet contained 2,440 calories and was made up of 460 Gm of carbohydrate, 61 Gm of protein and 40 Gm of fat. After a week of control observations, M O was given 300 mg of dinitrophenol daily for seven days and P O 225 mg daily for seven days. The results obtained are presented in the chart.

The metabolism of M O rose from a control value of -15 per cent to +10 per cent on the third day, and to +25 per cent, or a total of 40 per cent, on the seventh day of medication with the drug. In P O the rise was from a control value of -5 per cent to +50 per cent on the fifth day, and +45 per cent on the seventh day, or a maximum increase of 55 per cent. The daily nitrogen intake for M O was 11.8 Gm, the output varied from 9.5 to 13.5 Gm, an average of 12 Gm for the two weeks. The daily intake for P O was 9.7 Gm, the output varied from 6.5 to 10.5 Gm, averaging 8.8 Gm during both control and test weeks. Thus there was no significant change in the nitrogen balance of the control and test periods. In both subjects the urinary organic acids varied between 500 and 2,000 cc a day with no significant difference between the control and the test periods. This showed that the formation of acid bodies did not increase during the administration of the drug. M O lost 1 pound (0.45 Kg) during the control period and 5 pounds (2.3 Kg) during the medication with dinitrophenol. P O had an average weight of 1 pound less during the medication period than during the control period. The results in M O were particularly interesting, since they showed a significant weight loss without any commensurate increase in nitrogen output. This presumably indicated that the weight loss was not due to tissue destruction but to combustion of the fat or carbohydrate of the body. Subjectively, the patients felt warm and perspired easily during the medication period, but otherwise they felt quite normal.

On the whole this experiment demonstrated that even when a maximal amount of carbohydrate or minimal fat was present in the diet the usual increase in metabolism could be produced without disturbing the metabolic functions studied or causing undesirable symptoms.

HIGH FAT DIET

In this, or the third experiment the dietary fats were increased to the limit of tolerance and the carbohydrate correspondingly reduced in order to keep the caloric intake constant and the protein at 1 Gm per kilogram of body weight. For P A, who weighed 75 Kg, the total calories were 3,000, the carbohydrate

intake was 105 Gm, the protein 75 Gm and the fat 253 Gm. The diet of R U, who weighed 63 Kg, contained 2,520 calories and was made up of 90 Gm of carbohydrate, 63 Gm of protein and 212 Gm of fat. After a week of control observations, both subjects were given 225 mg of dinitrophenol daily for seven days. The results are presented in the chart.

The metabolism of P A rose from a control value of -15 per cent to +15 per cent on the fifth day, and to +35 per cent, or an increase of 50 per cent, on the eighth day after medication was started. In R U, metabolism rose from a control value of 0 per cent to values of +40 per cent on the sixth day and of +30 per cent on the eighth day. The nitrogen intake for P A was 12 Gm daily and the output varied from 8.5 to 15.5 Gm during the control period, and from 10 to 14.5 Gm during the medication period. The average of the values for nitrogen output during the control period was 12 Gm and during the medication period 13 Gm. The differences were too small to be of significance in view of the daily variations present. R U showed more definitely that the nitrogen balance was maintained. Here the intake level was 10.1 Gm and the output varied from 6.5 to 11.5 Gm a day, averaging 10 Gm during both the control and the medication period. The urinary organic acids showed an average of 750 cc a day during both weeks for P A, and 500 cc during both weeks for R U, again without evidence of increased acid-body production. The weights of both subjects varied considerably during the control period, but both lost 3 pounds (1.4 Kg) during the medication with dinitrophenol. The subjects were free from pronounced symptoms, even when their basal metabolism was maximally elevated, as in all previous experiments. There was only a moderate feeling of warmth and some increased fatigability on exertion.

Thus, dinitrophenol was effective in increasing the metabolism, without disturbing the basic metabolic processes studied although the subjects ate a diet containing an abnormally large amount of fat and a minimal amount of carbohydrate.

HIGH PROTEIN DIET

In the fourth experiment, the caloric value of the diets was maintained at 40 calories per kilogram, but the protein was increased to 1.7 Gm per kilogram of body weight. Carbohydrate and fat were apportioned as in a balanced diet. The diet for P A, who weighed 75 Kg, contained 3,000 calories, 300 Gm of carbohydrate, 125 Gm of protein, and 133 Gm of fat. The diet for P O, who weighed 61 Kg, contained 2,440 calories, 250 Gm of carbohydrate, 100 Gm of protein and 115 Gm of fat. After a week of control observations, both subjects were given 225 mg of dinitrophenol daily for seven days. The results are indicated in the chart.

The metabolism of P A rose from a control value of -15 per cent to +12 per cent or a rise of 27 per cent on the third day of medication and remained at that level. The metabolism of P O rose from +10 per cent to +50 per cent or an increase of 40 per cent by the fifth day of medication and remained at that level during the two remaining days of this period. The nitrogen intake for P A was 20 Gm a day, but the output never reached this level. During the control period it rose to nearly 18 Gm a day but averaged only 16.5 Gm during the medication period. Likewise the output of P O did not approach the intake level.

of 16 Gm a day until the end of the experiment, rising constantly to the end. It appears that on a high protein diet the nitrogen balance may remain positive, at least during the first week of medication with dinitrophenol. The urinary organic acids were remarkably constant throughout. In both subjects there was little variance from a value of 750 cc a day during the control and medication periods, again showing no tendency to acidosis. Although there was some variation in body weight, the two subjects did not lose more than a pound each during the medication with dinitrophenol. The symptoms were the same as those of the other diets discussed.

Thus, when protein formed an unusually large part of the diet, the increased metabolism of dinitrophenol did not disturb the basic metabolic processes of the body and caused no unpleasant symptoms.

COMMENT

Elevations in basal metabolism caused by dinitrophenol of between 27 and 50 per cent and persisting for periods of from seven to sixteen days were studied in subjects on controlled diets. The diets were all adequate as to caloric content on the basis of a normal metabolic rate, containing 40 calories per kilogram of body weight, but were abnormal in that they contained a maximal tolerated amount of carbohydrate, fat or protein. A normally balanced diet was also used for comparison. Such diets represented the extremes likely to be encountered in the dietaries of patients receiving dinitrophenol.

Dinitrophenol, used in doses of therapeutic range, caused increases in metabolism of the usual magnitude irrespective of the type of diet. The nitrogen excretion was never greater than the intake, even when the subjects lost as much as 5 pounds in body weight during one week. From this it seemed probable that there was no actual tissue breakdown during these short periods of heightened metabolism, but that the loss of weight was due to the utilization of stored carbohydrate or fat. This does not mean, of course, that tissue breakdown would not occur if the drug should be given over longer periods, but probably when materials other than protein are available these are utilized first. Thus the assumption might be made that, as long as the protein intake is adequate, any reduction in body weight is not primarily at the expense of the tissue proteins. The failure to demonstrate any change in the amounts of acid bodies in the urine indicated that the fat burned was consumed completely and did not tend to cause an acidosis.

These results indicate that dinitrophenol may be administered to patients on special dietary regimens over short periods without interfering with the usual metabolic effects of the drug. Therefore dinitrophenol would seem especially useful in obesity, in which, through burning of the stored fats, a reduction in body weight might be obtained. This reduction would be accompanied by a minimal destruction of body tissue since there was no demonstrable increase in the nitrogen output. Also because of the absence of unpleasant subjective symptoms, dinitrophenol might be valuable for increasing the depressed metabolism of various disease states. Thus, the palpitation and anxiety that often follow the administration of thyroid in sensitive patients might be avoided. This does not mean, however, that dinitrophenol can entirely replace thyroid, for there may be actions of this gland necessary or useful to the body in addition to its power of increas-

ing metabolism.⁵ In a later paper, we expect to discuss a number of actions of thyroid not possessed by dinitrophenol.

It may be added here that no demonstrable side actions have been observed in the human subjects reported in this paper under these adverse dietary conditions. However, among a large group of patients under observation in the Stanford clinics and from reports of physicians who have tried dinitrophenol, there would seem to be an incidence of something like 5 or 6 per cent of dermatitis. Such a reaction occurs with many other drugs and promptly disappears on withdrawal of the drug. As for other side actions, such as those resulting from renal or hepatic functional injuries, nothing definite has been demonstrated thus far by us, but observations along these lines are being continued and will be reported later.

CONCLUSIONS

1 The effects of alpha-dinitrophenol (1-2-4) on basal metabolism, nitrogen balance, urinary organic acids, and body weight were studied in subjects on balanced diets and on diets unbalanced by including maximal amounts of carbohydrate, fat or protein. The dinitrophenol was administered by mouth for periods of from seven to sixteen days. The caloric values of the diets were adequate for the normal metabolism of the subjects.

2 With the use of these diets, the basal metabolism was increased by from 30 to 50 per cent during medication with dinitrophenol.

3 The subjects excreted less nitrogen than they ingested, yet there were definite losses of body weight. Therefore, body proteins probably were not broken down. The output of urinary organic acid was not increased, thus indicating that the fats were completely burned without giving rise to acidosis.

4 Accordingly, dinitrophenol may increase metabolism in man, regardless of the energy materials of the diet, although it primarily promotes burning of carbohydrates or fat, at least during short periods such as those used in this study and on diets of adequate caloric value.

5 Clinically dinitrophenol is indicated in treatment for obesity and may be therapeutically useful in other disease states with depressed metabolism. Its main advantages over thyroxine or powdered thyroid would seem to be a prompt and vigorous rise of metabolism and an absence of disturbing subjective symptoms. Its use appears to be relatively safe for as long periods as have been studied so far.

The Way the Patient Lies in Bed—The fixed rigidity of meningitis is easy enough to recognize in the advanced case. Its early recognition in a case of obscure fever and headache or in subarachnoid hemorrhage may require the cooperation of the hands, but the decision to make the further test is often prompted by the appearance of unwillingness in the patient to move his head from the pillow. The adoption of the knee elbow position by a rheumatic child may be the first sign of pericarditis. Gull once surprised an anxious mother by telling her that her daughter with typhoid fever would recover before he had entered the sickroom. He had seen her sitting up in bed as he passed the door.—Ryle, J. A. *The Training and Use of the Senses in Clinical Work*. *Guys Hosp. Gaz.* 47: 421 (Oct. 28) 1933.

PERSISTING ERRORS IN THE TECHNIC
OF ORAL CHOLECYSTOGRAPHY

A PROCEDURE DESIGNED TO AVOID THEM

B R KIRKLIN, M D

ROCHESTER MINN

A prevalent belief that the intravenous method of cholecystography is consistently and definitely superior to the oral method in diagnostic results has stimulated me to reiterate my own convictions to the contrary and to recount certain rather common errors in the oral technic which may foster the opinion that it is less reliable than the intravenous method. For a long time I accepted the view that the intravenous method was somewhat more trustworthy, although I preferred to give the dye orally as a routine and reserved the intravenous test for cases in which the oral was indecisive. However, with added experience and the adoption of an appropriate oral technic I have become thoroughly convinced that, when the oral method is properly executed, its efficiency is equal to that of the intravenous method and that adverse comparisons of the two methods are usually based on results derived from faulty oral techniques.

Now it should be obvious that, to employ the oral test effectively, the dye must be given (1) in sufficient quantity, (2) in readily absorbable form, (3) in such a manner that it will not produce undue nausea or purgation, and (4) under conditions that will not hamper its evacuation from the stomach, its absorption from the bowel or its accumulation and concentration in a normal gallbladder.

From repeated trials with varying amounts I have found it best to give sodium tetraiodophenolphthalein (tetiophthalein), the compound almost universally employed, in a uniform dose of 4 Gm to adults. This is reduced for children in proportion to weight, but I have not found it necessary to vary the dose for small or large adults. If an amount considerably less is given the shadow of the gallbladder is likely to be faint or absent, and considerably larger doses tend to produce vomiting or purging or shadows of excess dye in the bowel which may obscure the gallbladder.

During the experimental stage of oral cholecystography, roentgenologists soon discovered that when the compound was administered in pills or capsules the masses often were not dissolved, and thus the test was vitiated. Even when the capsule or pill coating dissolved, the acid gastric juice, especially that of a fasting stomach, often combined with the exposed drug to form a viscid envelop which retarded or prevented breaking up of the mass. Thus the advantage of giving the compound in solution soon became evident, and this method is now generally employed. If the drug is dispensed in aqueous solutions they should be freshly prepared. It has been my observation that solutions more than twenty-four hours old are likely to produce nausea.

Next in importance to assuring absorbability of the dye is to give it in such a manner that it will be palatable and well borne by the stomach. Many persons tolerate the dye in simple aqueous solution but others find its taste disagreeable or are subsequently nauseated. Both of these objections can be largely overcome or greatly mitigated by mixing the solution with a glassful

of fruit juice or carbonated water. Grape juice is widely used, and I place it first on the list from which the patient may choose.

But it is not sufficient merely to disguise the taste of the dye and dilute it with an agreeable beverage, for even when thus taken on an empty or partially empty stomach, nausea and vomiting occur too often. Hence it is the more common practice to give it in association with a meal, although customs vary as to the quantity and character of the meal and the relative time at which the compound is taken. It seems to me that the significance of these factors is not appreciated as fully as it should be. After extended trials with meals different in amount and composition, and directing the compound to be taken at different times in relation to the meal, I have settled on the fixed routine of requiring the patient to take a full meal containing a minimum of fat and follow it immediately with the dye. This is, in my opinion, the most important factor in oral cholecystography.

The element of fat in the meal deserves especial consideration. More than one examiner has been interested in the plausible hypothesis that by including a substantial amount of fat in the meal the gallbladder would be emptied and thus rendered favorable for reception of the subsequently secreted dye-laden bile. In my hands, however, a faithful trial of this procedure resulted in a marked increase of positive diagnostic errors arising from faintness or absence of the shadow when the gallbladder was normal. Apparently the fat stimulates emptying of the gallbladder during the time when filling should occur. Since fat retards evacuation of the stomach, retarded absorption of dye by the bowel may follow. Delario¹ has shown by experiments on animals that fat renders insoluble a greater amount of the dye in the small bowel. Whatever the reason, I am certain that much fat in the meal will lead to a high proportion of mistakes in diagnosis.

The possibility that physiologic variations in absorption of dye by the bowel might lead to erroneous cholecystographic interpretations is still frequently mentioned, and at the beginning I had this apprehension. Repeatedly it has been emphasized that by the intravenous method a constant amount of the compound is put directly into the blood, whereas by the oral method the amount absorbed might vary so widely as to affect the reliability of the test. Yet I have not noted a single instance in which absence or faintness of the gallbladder shadow could reasonably be attributed to deficient absorption from physiologic causes provided no disturbing factor was introduced by the manner in which the compound was administered.

To avoid interference with absorption of the dye or with its entrance into and concentration by the gallbladder purgatives especially castor oil and other medicines which affect the intestine or biliary organs should not be taken by the patient during or shortly prior to the examination. Before cholecystography made its advent, purgation was often employed to prepare the patient for roentgenography of the gallbladder, and a few examiners persist in such preparation for cholecystography. It is desirable to cleanse the large bowel but this is best effected by having the patient employ enemas on the morning of examination.

The facts and opinions recited are not novel or peculiar to my experience. Indeed most of them were first pointed out by other roentgenologists, and all have

Tetraiodophenolphthalein. *J. Lab. & Clin. Med.* 16: 129-140 (Jan.) 1931.

received wide publicity. Nevertheless, oral technics continue to be exceedingly diverse, and in many instances they violate one or more principles which seem essential to me. Many examiners still give the dye in forms that hinder its absorption prescribe it in inadequate doses, direct it to be taken with a light meal or with one containing an excess of fats or several hours after the meal, or precede the examination with a purgative. Such lapses are often naively mentioned by sincere critics of the oral method and undoubtedly account for the disappointing results obtained. Any comparison of the two methods under these circumstances is bound to be inconclusive and inequitable. Further, I feel that by closer attention to the details described, some of the practitioners of the oral method would be rewarded by a surprising increase in its efficiency. It is to be conceded that rigid standardization of methods retards progress, but neglect to profit from past mistakes is equally hampering.

then cease breathing during the exposure. Voltage is proportioned to the patient's thickness, and the entire setting is equivalent to that which will exhibit details of bone structure. A constant target film distance of 26 inches (65 cm.) is employed and the exposure time varies from one-half to one second.

When the first set of roentgenograms is developed, it is inspected so that technical errors can be corrected. If the shadow of the gallbladder is obscured by gas, the technician massages the abdomen to displace the gas or requires the patient to repeat the exam. If the shadow is partly hidden by the ribs subsequent cholecystograms are made after inspiration and arrest.

The efficiency of this routine is exemplified in the results of the work during 1932. Of 4,676 patients examined 732 were operated on, and the cholecystographic diagnosis, whether positive or negative, was confirmed in 696 (95.0 per cent). Among 287 patients with normal cholecystograms, who were operated on chiefly for diseases other than that of the gallbladder,

Cholecystographic Data for 1932

Diagnosis	Observations at Operation									Diagnosis Confirmed at Operation, per Cent
	Cholecystitis									
	Cases	Gallstones	Tumors	Not Cracked	Grade 2	Grade 3	Grade 4	Miscellaneous	Normal	
Normally functioning gallbladder	281	4	2	19	4		1		267	81.0
Poorly functioning gallbladder	39	28 (71.8%)		5		1	2	1	2	94.5
Nonfunctioning gallbladder	106	99 (93.4%)	3	4	3		2	1	3	97.1
Normally functioning gallbladder with stones	124									
Poorly functioning gallbladder with stones	78	294	202	1						99.6
Nonfunctioning gallbladder with stones	92									
Tumor		6	6							100.0
Total		772	415	12	28	7	1	5	2	262

440 cases with positive cholecystographic data 6 errors (95.6 per cent correct). Of 732 diagnoses 696 (95.0 per cent) were confirmed.

415 cases with gallstones at operation 411 (99.0 per cent) with positive cholecystographic data. Of the 415 cases gallstones were visualized and reported in 294 (70.8 per cent).

40 cases with disease of the gallbladder at operation positive cholecystographic data in 40 (100 per cent).

262 cases without disease of the gallbladder at operation negative cholecystographic data in 27 (10.3 per cent).

At the Mayo Clinic for more than three years we have applied a routine which conforms to the foregoing principles. Reactions in the way of vomiting or distressing purgation have been few and in no case alarming. During the last year employment of the intravenous method was not deemed necessary in any case, and whenever reexamination was required the oral routine was repeated. Details of the procedure are as follows:

The patient receives 4 Gm. of sodium tetraiodophenolphthalein dissolved in 30 cc. of distilled water and is given the following printed instructions: (1) At 6 p. m. eat supper of usual amount, but without eggs, cream, butter or other fats. (2) Immediately after supper, empty the entire contents of this bottle (the dye) into a glassful of grape juice, stir well and drink all. (3) Do not take a laxative or any other medicine. (4) At 7 o'clock next morning take a rectal injection of warm salt solution until the water returns clear, and (5) do not eat breakfast, you may drink water, black coffee or clear tea.

Cholecystograms are made at the fourteenth and the sixteenth hour after the dye is taken, and again at the twentieth hour after the patient has taken a glassful of milk and cream in equal parts with his lunch.

For roentgenography the patient is placed in a comfortable position prone on the table, which is equipped with a flat Potter-Bucky grid. He lies with his cheek to the pillow, his arms forward and his ankles supported by a cushion. To secure thorough immobilization, a broad canvas band is drawn tightly over his back. He is required to exhale deeply and

surgical exploration confirmed the cholecystographic diagnosis in 257 (89.5 per cent). It is well known that the highest percentage of errors is caused by diseased gallbladders which maintain their function sufficiently to produce a normal shadow. The percentage of errors in such groups would probably be increased if the intravenous method were superior in eliciting shadows of functioning gallbladders. Of 445 patients with positive cholecystographic data, 439 (98.6 per cent) had cholecytic disease. It is precisely in this group that skeptics of the oral method would expect a high ratio of errors. Gallstones were found at operation in 415 cases, 411 (99.0 per cent) yielded positive cholecystographic data and the gallstones were diagnosed as such in 294 (70.8 per cent). In six cases in which a diagnosis of tumor of the gallbladder had been made the diagnosis was confirmed, but papillomas were also found in a few cases in which this specific diagnosis had not been made.

The personal equation was scarcely a factor, for many of the interpretations were made alternately by three of my associates in the section, and I attribute these results chiefly to our specific routine. Until such percentages have been surpassed by the intravenous method, I shall continue to apply and recommend the oral method.

ABSTRACT OF DISCUSSION

DR. WALTER L. PALMER, Chicago The accuracy of the oral method is carried out at the Mayo Clinic seems to compare most favorably with that obtained by the intravenous technic employed in other institutions. In a series of 2000 intravenous cholecystographies reported about three months ago by Dr. Ferguson and myself from the University of Chicago Clinics, the accuracy was not as great as that described today. During the past year we have been using the oral method and are quite satisfied with the results obtained, although they are not as good as Dr. Kirklin has reported. The oral method has two important advantages. First it is simpler and less expensive and, second, the reactions are less frequent and less severe. Now that it has been shown to be as reliable as the intravenous method, there would seem to be little reason for continuing to use the intravenous technic. Dr. Ferguson and I attempted a clinical evaluation of cholecystography. We found that the roentgen demonstration of stone was practically 100 per cent accurate. A normal visualization seemed to us to be more reliable than has been indicated in the present report. This discrepancy may be due to a difference in interpretation. In 287 cases of normal visualization, Dr. Kirklin reported finding stones or tumor in only 6 and cholecystitis of varying grades in 24. Considerable difference of opinion exists as to the pathologic diagnosis of cholecystitis. It is possible, according to our conception of cholecystitis, that we should have classified some of these as normal gallbladders. This might account for our attributing a higher accuracy to a normal visualization. A nonfunctioning gallbladder was found by us to be indicative of cholecystic disease in about 90 per cent of our cases when it was accompanied by a history of colic, but the accuracy was much less when there was no clinical evidence of gallbladder disease. Dr. Kirklin reports an accuracy of 97 per cent entirely irrespective of the clinical picture. From the clinical standpoint it is well to recognize that stones may be present in what appears to be a perfectly normal gallbladder roentgenologically and, conversely, that a poorly functioning or a nonfunctioning gallbladder may be perfectly normal. The final diagnosis, in my judgment, must be based on both clinical and roentgenologic evidence. I should like to ask Dr. Kirklin how frequently he finds reexamination advisable, and just what he considers to be the indications for it.

DR. ADOLPH HARTUNG, Chicago I should like to ask the author whether he makes any attempt as a routine to make an opaque meal examination in connection with the dye test. Before the dye test was used as frequently as it is now, a good deal of reliance was placed on the secondary gastrointestinal examination in connection with gallbladder disease. Since that time most of these cases I believe, are not checked up by such an examination. In quite a large number of cases in which the dye test was made as a routine procedure, the results were negative and an opaque meal was given for secondary signs. It seems to me that the percentage of error, especially in the cases of cholecystitis, might be brought down considerably by checking up in some way such as this. I have found in connection with normal gallbladder shadows that the meal gives some of these secondary signs either functional or organic indicating adhesions or gallbladder disease so that the percentage of error could be brought down materially.

DR. PAUL C. HODGES, Chicago Until a few years ago I used the intravenous method almost exclusively but one or two serious accidents with it caused me to change to the oral method. I supposed that the change was temporary until the difficulties could be overcome with the intravenous injection but as so frequently happens I have drifted along into a permanent arrangement without being particularly careful to be sure that the oral dye was being given in the best possible fashion. From what Dr. Kirklin says it is obvious that I have been making some mistakes. He uses 4 Gm. of dye and I have been giving only 3 Gm. He takes pains to put the patient in a comfortable position and has him suspend respiration in the expiratory phase. I have not paid much attention to the patient's comfort and have had him hold his breath on inspiration. Dr. Kirklin has the patient reach up and hold his own nose which I suspect is a very helpful maneuver in assuring suspended respiration. I have had an attendant hold the patient's nose in particularly difficult cases but I do this as

little as possible because I don't like to expose the attendants to the rays. The importance of complete immobilization cannot be overemphasized, and so Dr. Kirklin's efforts directed to that end are of great practical importance. I have had a little experience with rapid stereoscopic exposures made with the patient standing in front of a vertical cassette changer, a Lysolm stationary grid interposed between him and the film. Films of this sort hold great promise. I should like to know whether Dr. Kirklin is using the pure dye or one of the commercial preparations containing a vehicle and flavoring matter.

DR. H. A. OLIV, Chicago I think that I have had better success using the pure salt and dissolving it in water and mixing it with grape juice. In the event that the patient is unable to take grape juice, I use any fruit juice, because it is the acid in the fruit juice that precipitates the salt, which is redissolved when it enters the duodenum. Recently I have been interested in the complication of diarrhea. It occurred to me that giving camphorated tincture of opium with the dye would overcome this objection. I think that in the controversy about oral and intravenous methods one important matter has been overlooked, and that is the chronically inflamed gallbladder which is out and out clinically a surgical case. I think that Graham's appreciation of the use of the liver test combined with the salt should not be overlooked. That is called iso-iodeikon (phentiothaleim sodium) and I suppose it is as familiar as iodeikon (sodium tetraiodophenolphthaleim). By ascertaining the liver index one is able to obtain the amount of liver damage and the degree of operative risk many days prior to operation. I agree with Dr. Kirklin that the fat meal is of decided advantage especially to show when the gallbladder is almost completely empty or partially empty. Last month I observed three gallbladders which appeared normal in a cholecystogram. These were three strawberry gallbladders, and I should like to ask Dr. Kirklin whether he has had a similar experience.

DR. B. R. KIRKLIN, Rochester, Minn. I have reported only cases which have been checked pathologically with the exception of those cases in which the operation was for other abdominal conditions and the gallbladder was merely palpated or inspected and determined to be normal and therefore not removed. Some one has asked regarding the indications for reexamination and what percentage of the cases are reexamined. The indications for reexamination are unsatisfactory films or any doubt that the patient has followed instructions. Approximately 8 per cent of the total number of the cases are reexamined. The dye is usually repeated the night following the first examination. In reviewing those cases in which a normal functioning gallbladder has been reported and small stones have been found, it has invariably been learned that the cause of the error has been an attempt to interpret films of inferior quality in that there was movement on the part of the patient or gas in the overlying segment of bowel which obscured the stone shadows. I feel that if one has satisfactory cholecystograms and the gallbladder is functioning normally, stones can invariably be ruled out. As evidence of the importance of meticulous technic in cholecystography the percentage of accuracy has increased hand in hand with the improvement in technic. I have not followed the method of examining the stomach and gallbladder on the same day. I prefer to make cholecystograms on the day preceding examination of the stomach, although I can see no reason why they cannot be made the same day. Dr. Hartung mentioned the diagnosis of gallbladder adhesions which brings up a very important question. I have little confidence in my ability to diagnose gallbladder adhesions. Early in this work I thought I could recognize adhesions by deformities of the gallbladder contour, but I have since learned that there is no relation between adhesions and deformity of the gallbladder wall in cholecystograms nor does a smooth gallbladder contour rule out adhesions in my experience. Dr. Hodges has asked what dye is used. For some time I have employed sodium tetraiodophenolphthaleim and have found it a most satisfactory preparation. I do not use camphorated tincture of opium as a routine but I can see some advantages in its use. Some one has asked regarding the strawberry gallbladder. I have found that the cholecystograms of an uncomplicated strawberry gallbladder will almost invariably show that it is functioning normally.

EVANSTON, ILL

This article is limited to (1) the enumeration of a number of terms for stiff, painful shoulders with practically the same clinical syndrome, (2) an analysis of the pathologic changes found in dissections, autopsies and operations, (3) a study of the role that rupture of the supraspinatus tendon, capsule and subacromial bursa plays as an etiologic factor, (4) a review of a few cases to emphasize the importance of apparently trivial symptoms, usually overlooked or neglected as unimportant, (5) a brief outline of the essentials of treatment, based largely on a study of 340 shoulders in dissecting rooms, (6) a description of a simplified operation for tendon and capsule repair.

In particular, my purpose is to direct attention to evidence that rupture of the supraspinatus tendon is apparently the primary exciting cause of most "stiff, painful shoulders," and that an early recognition of that fact, with prompt proper treatment, will bring about much earlier and better end-results.

Duplay,¹ three score years ago, described an involvement of the subacromial bursa from trauma and named this condition "scapulo-humeral peri-arthritis." Dickson and Crosby² used the term "peri-arthritis of the shoulder" in their recent analysis of 200 cases. And Codman,³ a pioneer in research work on the shoulder used "rupture of the supraspinatus tendon," believing such a term to be descriptive of a constant part of the pathologic process found in these shoulders. Royal Whitman⁴ used the term "stiff, painful shoulders" and "peri-arthritis of the shoulder" synonymously.

In the evolution of the shoulder from a walking weight-bearing joint to a weight-carrying one, much strength, stability and durability have been lost. The shoulder joint has the greatest range of motion and the most extensive moving capsule, and, relatively, the glenoid has the smallest, shallowest joint socket. Such a joint is particularly prone to injury, so that it is not surprising that Codman found a complete rupture of the supraspinatus tendon to every twenty shoulders examined, and one incomplete rupture to every third shoulder. In a study of 340 shoulders, my observations were 1 complete rupture of the supraspinatus tendon to every 28 shoulders examined, and 1 incomplete rupture to every 6 shoulders.

The complete ruptures showed much fraying of the tendon and almost no signs of repair, while seventeen of the forty-four incomplete ruptures of the supraspinatus tendon had healed, nearly closing the rupture gap. Had all the incomplete ruptures been immobilized with the arm well elevated, it is my belief that there would have been sufficient approximation in the entire forty-four to result in a satisfactory healing of the damaged tendons and contiguous structures.

Deposits were found in more than a third of the cases of rupture. These deposits were in and about the supraspinatus tendon, as stressed by Brickner,⁵ Codman, Moschcowitz⁶ and others. It was a significant fact that practically all of the gross pathologic changes found were in and about the ruptured supraspinatus tendon. Furthermore, in the absence of tears of the tendon, practically no degenerative changes, such as fatty, chalky or putty-like deposits, were found. Apparently, rupture was the first link in the chain of pathologic changes.

Dickson and Crosby, "in an effort to elucidate the relationship of trauma, foci of infection and metabolic factors in the etiology," concluded that "there must be some common denominator, which cannot be accounted for at present." In the light of Codman's and my own research, that "common denominator" may be rupture, much or little, of the supraspinatus tendon. The rupture almost universally overlooked, for reasons to be

given later, may be and probably is the primary exciting cause, and inherent structural weakness of the shoulder, a poor blood supply, metabolic factors and foci of infection are secondary, though important, once a rupture has occurred.

Codman believes that virtually every rupture of the supraspinatus tendon is caused by contraction of the supraspinatus muscle and that tears are rarely produced by direct trauma. For the most part, I concur.

From St. Francis Hospital.
Read before the Section on Orthopedic Surgery at the Eighty-Fourth Annual Session of the American Medical Association, Milwaukee, June 16, 1933.

in that belief. Occasionally, a dislocation of the shoulder is accompanied by a tear of the tendon and capsule, for example, two such cases were found in my work, and Wilson⁷ reported one case. Other cases are as follows:

One of Wilson's patients produced a complete rupture of the tendon in an attempt to toss a stone up out of a trench. Another was pulling down on a chain hoist, his hand slipped, and in his effort to regain his balance, violent action of the supraspinatus muscle ruptured the supraspinatus tendon.

Fig 2—AA represents the section of acromion removed B the supraspinatus tendon C the subacromial bursa D the lower portion of the capsule E the infraspinatus fossa with the infraspinatus muscle and tendon removed

One of Codman's patients produced a rupture in an effort to recover his balance, when a saddle girth he was tightening suddenly broke.

One of my patients, a middle-aged woman, slipped as she stepped onto an oiled floor. As her feet shot forward, she raised her arms to regain her balance and thus ruptured the right supraspinatus tendon.

Another patient, a young man of 24, not accustomed to hard work, undertook the task of passing up cases of soda pop. After six weeks of this hard labor, which put the supraspinatus tendon to constant strenuous use, he noticed one evening after work a dull aching pain in the right shoulder. He was unable to resume his work because of pain and disability. When I saw the case six months later there was limitation of abduction with extreme atrophy of the spinatus muscles. A coarse crunching crepitus was felt about the greater tuberosity as it approached the acromion. Pain and tenderness were present in the same area. It would appear that repeated sprains, a rupture of a few fibers at a time had occurred till at the end of six weeks the entire tendon was torn from its attachment. In this case now over two years old the patient has not been operated on though Wilson operated in a similar case in which the patient produced piecemeal by his routine folding of cloth a complete rupture of the supraspinatus tendon.

Another patient of mine, a middle-aged blacksmith in starting down to the cellar lost his balance and in his effort to regain his equilibrium the sudden contraction of the spinatus muscles ruptured his supraspinatus and infraspinatus tendons, making a gap 2 by 2 1/2 inches (5 by 6.3 cm) through which the head of the humerus appeared at operation.

The history in conditions of the shoulder is of extreme importance and in taking it the most painstaking inquiry as to every possible detail from many angles will with surprising regularity disclose that there has been a sudden stress on the spinatus tendons or that there has been long continued overuse.

A surprising and misleading fact is the little or no pain noticed at the time of the rupture, whether the latter occurs at once or piecemeal, as in the cases described. The pain has a sticking or cutting quality and lasts but a moment, so that the incident is usually forgotten. Some hours may elapse before aching and disability set in, dependent somewhat on the extent of the trauma. When there is extensive rupture, few patients complete the day's work. At night the pain is much worse, often preventing or interrupting sleep. On abduction, pain is usually cutting as the arm nears the horizontal, and the patient may drop his arm to the side, owing in part to weakness and in part to pain. Pain is complained of in the deltoid area, and it may radiate up or down. Tenderness is often less marked the first two or three weeks than later. It is usually elicited around the greater tuberosity, particularly proximal to its upper border. In complete rupture of the supraspinatus tendon, well marked atrophy of its muscle has been observed as early as two weeks after the rupture occurred.

Ridlon⁸ confessed, "that the difficulties encountered in treatment of injuries to the shoulder joint have always been more troublesome and more obscure than the difficulties in treating all other joints put together." Lovett⁹ once said "No common injury is so badly treated, save possibly the spine, as injuries to the shoulder." Part of the reason for this unsatisfactory treatment would seem to be a lack of recognition of the fact that seemingly trivial trauma may, and frequently does, produce a tear in the structures of the shoulder joint, and that the tear is often accompanied by little or no pain. This lack of recognition has come about, in part, because shoulders are rarely operated on for relief, and painful shoulders, not being fatal, provide no autopsies.

However, because of the astonishing number of ruptures found in routine examination of shoulder joints by Codman and myself, it would seem justifiable, in cases of stiff, painful shoulders not greatly improved in two or three weeks by immobilization in abduction,

Fig 3—A is the acromion B the subacromial bursa C the partially ruptured and frayed supraspinatus tendon D the capsule E the glenoid cavity

to assume that a rupture has occurred. Of course, along with the local treatment a careful general examination and treatment of any abnormality, such as diabetes, gout, hyperthyroidism or hypothyroidism and loci of infection should not be neglected.

In cases where a steady marked improvement has not occurred during the first three weeks it is my belief that an exploratory operation should be done under

local anesthesia to settle the diagnosis and to insure comparatively early proper treatment

OPERATION

Step 1 is performed under local anesthesia to confirm or refute the diagnosis, step 2, under general anesthesia to repair the rupture

1 The exploratory incision starts over the acromion, $\frac{3}{4}$ inch (2 cm) back of its tip, and extends distally

Fig 4—AA is the sector of acromion removed B complete rupture of the capsule subacromial bursa and supraspinatus tendon with wide separation C the subacromial bursa with a wide opening into the shoulder joint D the dependent capsule

2 inches, parallel to the fibers of the deltoid muscle. The deltoid fibers are separated, and the underlying subacromial bursa is opened. If the floor of the bursa is intact there is no rupture, in which event the incision is closed, and the convalescence will not be appreciably delayed.

2 In the case of a rupture needing repair, the second step of the operation is continued under a general anesthetic. The outer end of the incision is extended 1 inch (2.5 cm) and the inner end 2 inches. The acromion is cut through from without inward, starting $\frac{1}{2}$ inch (1.2 cm) back of the acromioclavicular joint. A gutter is cut along the upper border of the greater tuberosity, and the edge of the retracted rupture is trimmed, while the clavicle is retracted forward. Through the base of the greater tuberosity four or five drill holes are passed from without, emerging in the gutter. Strong linen or silk on a curved needle is passed from without through hole 1, then through the torn tendon and back through hole 2. A second suture is passed similarly through hole 2, then through the tendon and back through hole 3, and so on, till all the sutures are placed. The sutures are then tied, while the arm is elevated. The bone springs back into place as soon as traction is withdrawn. A few buried sutures are inserted and the skin is closed with a continuous dermal suture. The arm is put up, well abducted, on a light supporting splint for two weeks and then is placed in a sling. The patient is encouraged to use the arm as soon as the soreness from the operation subsides.

SUMMARY

1 Stiff, painful shoulders, periarthritides of the shoulder, subacromial bursitis and rupture of the supraspinatus tendon are not strictly independent entities. They are the links in the chain of pathologic changes found in chronically disabled shoulders.

2 Rupture of fibers of one or both spinatus tendons with the inevitable injury of the capsule and subacromial bursa, is the beginning of most pathologic processes in the shoulder, which progress needlessly because of hazy diagnosis and poor treatment.

3 The great frequency and abundance of pathologic change found in routine dissection of shoulders indicates that it is largely overlooked and, for the most part not even suspected in cases of disabled shoulders.

4 Early diagnosis and consequent proper treatment will make operative treatment of incomplete ruptures rarely necessary.

5 Late diagnoses and late operations mean relatively poor end-results.

6 The operation herein described seems to have advantages over other operations for repair of one or both spinatus tendons.

ABSTRACT OF DISCUSSION

DR EDWIN W. RYERSON, Chicago: Dr Fowler has done a fine piece of work in his investigation. I have seen very few patients in whom the supraspinatus tendon had been torn. I have seen several old cases in which operation would not have been advisable and have refused to operate. Two weeks ago I saw a boy who had a reasonably recent tear which was easily demonstrable because a little piece of the greater tuberosity had been torn off. I think that operation should be done in this case but I question very much whether the old chronic tears will give good enough results after operation to make it worth while. I have done none in the old cases. The cases presenting the masses of gritty, calcareous matter, either in the supraspinatus tendon or, as I think in some cases, in the bursa sometimes require operation and sometimes do not.

Fig 5—AA is the sector of acromion removed B complete rupture (as in fig 4) almost approximated by elevation of the arm C the subacromial bursa D the lower portion of the capsule

DR F. J. GAENSLEN, Milwaukee: Dr Fowler has done an excellent service in further elucidating the subject of stiff and painful shoulders. I enjoyed especially his collection of anatomic specimens in the Scientific Exhibit. One cannot but be impressed with the correctness of Dr Codman's and Dr Fowler's statements that the injury is of relatively frequent occurrence. I cannot explain the fact that so few cases are seen with marked late disability in the absence of operative repair or adequate conservative treatment at the time of the injury. The gradual fraying of the supraspinatus tendon by repeated

minor injuries, associated with overuse of the arm in abduction, is apparently not unusual, although more severe single traumas undoubtedly are responsible for the majority of actual tears. A few years ago, while I was in Boston with a small group of Wisconsin surgeons, Dr. Codman discussed this problem for us at length. I remember his saying that the diagnosis of bursitis is perhaps no more justified than a diagnosis of peritonitis. Differentiation of the cases into actual rupture, complete or incomplete, calcified deposit in the tendon, or chronic adhesions should be possible in the great majority of cases.

Dr. EDSON B. FOWLER, Evanston, Ill. In regard to Dr. Ryerson's hesitancy to operate in old cases it is well to state that Codman and Wilson reported old cases. Twenty per cent of the patients were able to resume their former occupations. In 80 per cent the condition was more or less improved and the patients were able to do a variable amount of light work. The operation as performed by Codman or Wilson gives sufficient lysis of the capsule and tendon to permit adequate closure of the rupture gap. In the old cases it is necessary to incise the capsule along the anterior and posterior borders of the tendon as well as under the tendon where it leaves the capsule. This permits the suture of the retracted structures to the greater tuberosity with a good closure of the rupture gap. Very rarely, deposits are found in the subacromial bursa, as stated by Dr. Ryerson and as found by myself and others. The piecemeal ruptures and associated erosions noted by Dr. Gaenslen are far more common than the sudden complete rupture of the tendon and associated capsule and bursa.

USE OF PHENYLMERCURIC NITRATE IN TINEA AND YEAST INFECTIONS OF THE SKIN

PRELIMINARY REPORT

BENJAMIN LEVINE, MD
CLEVELAND

During the past three years, Weed and Ecker¹ reported on two new mercurials showing unusual bactericidal and fungicidal properties coupled with low toxicity for man and animals. Of chief interest and importance was phenylmercuric nitrate.

They studied the effect of phenylmercuric nitrate on twenty pathogenic fungi of man and it was shown that with the exception of *Achorion violaceum* all the implanted fungi failed to grow in mediums containing 5 and 1 per cent of the saturated solution of phenylmercuric nitrate. Subcultivation on new mediums proved that the majority were killed, since only two (*Trichophyton acuminatum* and *Achorion violaceum*) from the medium containing 5 per cent saturated solution of phenylmercuric nitrate grew. However, from the medium containing 1 per cent five subcultures showed growth. They also showed that phenylmercuric nitrate readily killed six strains of wood-destroying fungi. Hatfield,² one year later corroborated the fungicidal value not only of phenylmercuric nitrate but also of phenylmercuric chloride.

The high bactericidal efficiency of phenylmercuric nitrate has also been confirmed experimentally by Birkhaug³ and clinically by Biskind.⁴

At the suggestion of Dr. L. F. Ecker the effectiveness of this compound (phenylmercuric nitrate) was studied in the treatment of fungous and bacterial infections of the skin.

FORMS OF MEDICATION

As it was necessary to determine an efficient concentration of the drug for dermatologic use and to find an effective vehicle, a number of mixtures were prepared and employed. The optimum concentration was derived in the following manner. A lotion consisting of phenylmercuric nitrate 1:1,000 in an emulsion of gum tragacanth was used. The product was highly efficient but its continuous application proved to be moderately irritating to the skin, owing either to too great an original strength of the emulsion or to evaporation and resultant concentration. A lotion was then prepared containing phenylmercuric nitrate in a dilution of 1:1,250. This was decidedly less irritating. Application of a simple aqueous solution of phenylmercuric nitrate 1:1,250 by itself produced good results, but the possibility of drying contraindicated its use. Subsequently, an ointment was prepared consisting of equal parts of wool fat and an aqueous solution of phenylmercuric nitrate 1:1,250, the solution being gradually added to the lanolin in the course of emulsification in an electrical mixer. In general, this ointment containing the drug in a concentration of 1:2,500 proved more satisfactory than the lotion. After further experimentation an ointment was made containing the phenylmercuric nitrate in a concentration of 1:1,500 by weight with the addition of 10 per cent of glycerin. This ointment proved to be most satisfactory. A 1:1,000 concentration again proved too irritating for general uses. The ointments found to be most efficient were made with two hydrophilic bases containing cholesterol derivatives. Both these ointment bases containing phenylmercuric nitrate in a dilution of 1:1,500 gave excellent results and showed apparently better penetrating properties. They were unquestionably superior to the ordinary hydrous wool fat preparations.

METHOD OF APPLICATION

The patient was instructed to cleanse thoroughly all affected parts prior to the use of the ointment or lotion. This was done by means of soap and water and a soft brush. A moderate amount of one of the mixtures was gently rubbed into the infected area twice daily, night and morning. Overtreatment was avoided.

NUMBER OF CASES

Of 262 cases studied 205 were carefully followed up and the patients discharged as cured. The remaining 57 patients were seen but once after the beginning of treatment and the data in these cases remained incomplete. Of the 205 patients, 193 had tinea and the remaining 12 had interdigital saccharomycosis.

INTERDIGITAL SACCCHAROMYCOSIS

It has been a common experience among dermatologists to find interdigital saccharomycosis unresponsive to therapy. For this reason special attention was paid to this type of infection because favorable therapeutic results would here definitely establish the value of the drug. The results obtained with both the lotion and the ointment proved that they were efficient in the treatment of this intractable infection: twelve out of fourteen patients being cured and the other two markedly improved. Occasionally the lotion proved superior to the ointment. The length of time necessary to effect the cure varied from two days to four weeks with an average of two weeks. One patient cured in two days, used a lotion in the dilution of 1:1,000.

The outstanding case was that of Mrs. K. K. who had had the infection constantly for twelve years.

⁴ Hatfield, J. *Am. J. Hyg.* 1934 (May-June) 1933.
⁵ Biskind, L. H. *Surg. Gynec. & Obst.* 57: 351 (Aug.) 1933.

During this time she was under continuous treatment with various forms of medication, such as tincture of iodine, 5 per cent aqueous solution of copper sulphate, Whitfield's ointment and an ointment containing oil of cassia, oil of cloves and iodine, without results. Phenylmercuric nitrate ointment 1:1,000 was tried and found to be somewhat irritating. A few days later she was given a 1:2,000 ointment, which did not irritate. There was a complete cure in two weeks with no recurrence in three months.

Two of the patients had recurrences, one of whom has since been cured and the other of whom is now under treatment. Usually there was complete relief of pain and pruritus after one application.

TINEAS

Of the 193 cases of tinea treated, all were cured. There was a total of 110 patients with tinea of the feet, 21 of whom had a secondary epidermophytid of the hands. In each instance the epidermophytid cleared up promptly, usually before the tinea of the feet was cured. One of the cases of epidermophytid of the hands showed the importance of proper differentiation between the primary infection and the secondary allergic reaction. This patient presented a vesicular scaly eczematoid eruption on both hands of seven years' duration. At no time were the hands free of this eruption, being worse at certain times than at others. Examination of the feet when first presented showed no apparent disease. After three weeks with phenylmercuric nitrate ointment 1:2,000 applied twice daily to the hands, there was no improvement. The ointment was discontinued and roentgen therapy instituted. The first treatment caused most of the lesions to regress. Further treatments, however, aggravated the lesions. A total of 2 skin units was given. One week after the last roentgen treatment, when the hands were at their worst, the patient's feet were reexamined. They showed some fissuring and scaling under each of the little toes. The patient was instructed to apply the ointment on her feet only. Four days later her hands and feet were both healed. There has been no relapse in a period of over five months. Similar results were obtained in other cases with epidermophytid or trichophytid eruptions. In each instance the treatment of the primary focus relieved the patient from the secondary eruption.

Twenty patients with tinea of the hands were treated. All of these were cured. They did not show involvement of the feet.

Of the twenty-four patients with tinea cruris all were cured by the use of the 1:1,500 ointment.

Five patients suffered from tinea of the anal region. The outstanding feature was the relief from pruritus noted usually after one application of the ointment. The same is true of pruritus vulvae. However, further investigation of a larger series of these cases is necessary.

E. G., a man, aged 36, had severe pruritus and due to tinea for the past few years. During this interim he was seen by several physicians, one of whom gave him seven roentgen treatments. Roentgen therapy produced temporary relief lasting from one to four months. He also had used 2 per cent salicylic acid in alcohol and later a modified Whitfield ointment. The latter treatment gave him partial relief only and later no relief at all. When seen, he was exhausted and had lost con-

siderable weight from lack of sleep caused by the severity of the pruritus. The anal region and intergluteal cleft were macerated, excoriated and infiltrated, the process extending down over the perineum to the scrotum. When the patient was seen three weeks later, the tinea was completely cured. The pruritus, he reported, disappeared after several applications of the ointment. There was no recurrence ten months later.

Five cases of tinea of the axillary regions were treated with complete relief. In one case the 1:1,000 lotion proved to be superior to the ointment.

Tinea circinata of the glabrous skin presented an interesting series. Twenty-one cases were studied occurring between the ages of 1 and 60 years. The most interesting case was that of Mrs. W., who had a generalized tinea corporis of seven or eight years' duration. A large variety of ointment and roentgen therapy had been used to no avail. The x-rays were used to the extent that it was feared that any further irradiation might cause an atrophy. Within three weeks the patient was completely cured by a 1:1,250 lotion of phenylmercuric nitrate. Another patient showing an extensive tinea circinata of the arms and legs responded more readily to the lotion than to the ointment. Most of the patients were treated with the ointment. The time necessary to effect a cure varied from three days to one month, as a rule, ten days was sufficient.

Tinea versicolor responded more favorably to the lotion than to the other preparations. All six cases seen cleared up with the lotion in the dilution of 1:1,000. As a rule this type of tinea responds in from three to seven days.

So far, the number of cases of tinea of the scalp and face treated with phenylmercuric nitrate are too few to justify any definite conclusion. One case of tinea of the scalp was cured after two or three months of treatment. Four other patients, on returning at the end of one week, showed definite improvement. One case of tinea barbae was cured in ten days.

The majority of our cases were gathered from the dispensary and a considerable number of cases consisted of physicians and their families. It was among these that the most startling and satisfactory results were obtained because of more intelligent and consistent use of the drug. Many of our dispensary patients obtained relief and failed to return, while others used the drug spasmodically. These facts also account for the longer duration of the treatment in these cases.

It is necessary to point out that occasionally patients sensitive to mercury are encountered who receive mercurial burns from this treatment. All those seen in this series (seven) were readily relieved by the use of a bland ointment.

CONCLUSIONS

1. In a series of 262 cases of tinea and yeast infections of the skin, phenylmercuric nitrate in ointment or lotion form was used. Two hundred and five cases were cured, the remaining fifty-seven cases were definitely improved but these were not followed to completion of treatment.

2. Phenylmercuric nitrate proved highly efficacious in the treatment of these cases producing cures when other standard medicaments had failed.

3. In the great majority of cases, no untoward results have been seen from its continued use. In the occasional

cases in which irritant effects occurred these cleared up readily on withdrawal or on substitution of a less concentrated mixture

4 All the phenylmercuric nitrate used in this series of cases was prepared by Dr Ecker and conforms to his specifications

5 Phenylmercuric nitrate is presented as a distinct contribution to the dermatologic armamentarium

TUBERCULOSIS AMONG NEGROES

SOME OF THE PROBLEMS THAT COMPLICATE ITS CONTROL

C ST C GUILD, M D
NEW YORK

A comprehensive review of the literature dealing with tuberculosis among Negroes, and conferences with many of the outstanding men who are interested in this problem, indicate that control measures are complicated by a lack of definite information on several points of fundamental importance, which often reveals itself in a multitude of conflicting opinions

The present status of knowledge on several of these points will be briefly discussed in the light of recent contributions, consideration being given to the extent to which control measures appear to be handicapped by lack of definite information

DO NEGROES HAVE A RACIAL LACK OF RESISTANCE AGAINST TUBERCULOSIS?

A vast amount of literature has been written on whether Negroes have a racial lack of resistance against tuberculosis. In general, it may be said that the majority of authors are of the opinion that they do, but many publications, particularly those of former years, appear to be based on conjecture rather than fact. Within the past year, three very interesting contributions have appeared dealing with this racial factor

In view of Bogen's statement that "an investigation of the fate of a group of patients known to have been already infected with the tubercle bacillus and living under approximately similar conditions may shed some further light upon the problem of racial susceptibility to the disease," special interest attaches to a study by Dr Taliaferro Clark of some 6,000 hospitalized veterans, a group somewhat removed from the cloud of economic conditions and in which he believes the two races are economically equal. The study showed that "upon final disposition of the cases admitted while the disease was in a moderately advanced stage, 50 per cent of the colored and 70 per cent of the white patients showed improvement, quiescence, arrest or apparent arrest while 39 per cent of the colored as compared with 17 per cent of the white patients died while in hospital." Dr Clark points out that while in these economically equal groups the Negro death rate is double that of the white, in unselected population groups it is usually three or four times as high. His conclusion is that "the race factor is working in combination with the economic one against the Negro."

Pinner and Kasper reiterating that "probably the only definitely established fact about immunity is the diminution of spread in a sensitized organism is com-

pared with a nonsensitized one," proceed to show from postmortem examination of 303 Negroes and 219 white patients dead of tuberculosis that

1 Hematogenous spread occurs twice as often in Negroes as in white persons

2 Spread by way of the lymphatics occurred nearly seven times as frequently in the Negro as in the white group whereas isolated phthisis was present in nearly half the white patients and in less than 3 per cent of the Negroes

These authors while recognizing the fact that environmental conditions are one of the most important factors causing the high incidence of tuberculosis among Negroes, believe that there is also a true racial difference

Dr F C S Bradbury, in his investigation of incidence of tuberculosis in certain Tyneside districts, found a greater incidence of tuberculosis in the Irish than in the English. Even when such factors as poverty, overcrowding and large families were controlled he concluded that "there is evidence of a racial factor which is responsible in part at least for the relatively high incidence of tuberculosis in the Irish."

Now just what do the various authors mean by a racial factor? Clark and Bradbury are not specific on this point. Pinner and Kasper have in mind a true genotypic difference (anatomic or physiologic). Most of the earlier authors and many of the more recent ones, however when they refer to a racial factor, mean, to quote Graudy, for example "the result of the Negroes' relatively short period of contact with tuberculosis." As Reuter points out, lack of experience with a disease is a historical and not a racial or biologic fact. Race has nothing to do with it, since two groups of the same biologic ancestry would show similar relative differences in immunity to a disease if through a series of generations one had been exposed to its selective efforts and the other isolated from its attack.

It would appear, then, that while conclusive proof is lacking the weight of opinion and evidence indicates that in addition to his environmental and economic handicaps the Negro has a lack of resistance to tuberculosis, which may be due to a true biologic difference or merely a present expression of unlike historical experience.

While accurate information as to this lack of resistance would be of the utmost interest, it would probably have but little effect on control measures. To change the anatomy or physiology of the Negro would be a difficult undertaking and only time can correct his lack of historical experience. In the meantime however, the importance of his environmental and economic handicaps is universally recognized, and this must obviously be the point of attack.

WHAT IS THE MOST EFFECTIVE TUBERCULOSIS CONTROL PROGRAM FOR THE SOUTHERN STATES WITH THEIR LARGE NEGRO POPULATION AND LIMITED FINANCIAL RESOURCES?

Not only is the Negro handicapped in his fight against tuberculosis by his low economic status, both as an individual and as a race but the fact that the majority of the Negro population is concentrated in a relatively small number of states, whose financial resources are meager still further complicates the problem of control.

Despite the large northern migration that occurred during the period 1915-1930 nine million Negroes (or

Read before the Section on Preventive and Industrial Medicine and Public Health at the Eighty-Fifth Annual Session of the American Medical Association, Milwaukee, June 16, 1934.

roughly, three fourths of the Negro population) still live in the following thirteen states, all essentially Southern: Alabama, Arkansas, Florida, Georgia, Kentucky, Louisiana, Mississippi, Missouri, North and South Carolina, Tennessee, Texas and Virginia.

Eight of these states have more than half a million Negroes each, and in nine of them Negroes constitute more than one fourth of the total population.

Even granting the argument advanced by sociologists that with the return of prosperity this trend to the large cities of the North will be resumed, it is evident that for a long time to come the vast bulk of the Negro population will be found in the group of states just enumerated.

Furthermore, of the nine million Negroes living in these states, approximately eight million (or two thirds of all the Negroes in the United States) reside in the rural districts, the towns and the smaller cities of the South, and it is the problem presented by this group that I shall briefly consider.

In general, it may be said that most of the Negroes of this rural, town and small city group live in communities that are unable to finance adequate control measures as defined by present standards. Unlike their cousins residing in the large cities, they must depend very largely on the state to provide facilities particularly in the matter of hospitalization. Several of the states listed make no provision whatever for sanatorium treatment for either white or colored patients, and in most of the others the facilities provided are grossly inadequate.

Certainly, the matter of providing an effective service for the control of tuberculosis among Negroes (or, for that matter, white persons) is an extremely complicated one in many of the Southern states, owing to their low economic status. In fact, one may say that there are as yet in existence no adequate data on which to formulate a program that would be reasonably effective and yet within the financial ability of most of these states, and this is particularly evident at the present time.

I shall consider a few of the attempts at meeting this situation.

Tennessee—The tuberculosis study that is being carried on by the Rockefeller Foundation in Wilkes County under the direction of Dr. Bishop has as one of its objectives "the development of a program of control of tuberculosis designated to have practical state-wide application."

A qualitative appraisal of tuberculosis nursing service by officials of the state department of public health gives every indication of materially increasing the efficiency of the service rendered, with no additional cost.

Dr. Overton of the City Health Department of Nashville is experimenting extensively with the use of BCG. It is possible that his results and those of others who are working with this organism will be of value, since BCG, if it can be shown to yield favorable results, is within the financial reach of even the poorest state.

Alabama—The diagnostic clinic of the Alabama State Board of Health has already standardized on the use of the paper film.

One of the objectives of the study now being made for the Rockefeller Foundation by Dr. Graham in Opelika is to determine "whether or not satisfactory isolation of the tuberculous patient may be achieved at home by the utilization of portable screened cottages

and screened porches, together with the provision of adequate public health nursing service, and what it will cost to secure effective isolation by these methods."

Georgia—Dr. Haygood is now working on a plan for a district tuberculosis nursing service to be operated in conjunction with the state tuberculosis clinic and financed by small contributions from the counties served. The diagnostic clinic of the state health department is trying out the paper film and also planning a change in procedure which, it is hoped, will enable it to examine a much larger number of patients with only a slightly increased expenditure.

It is evident that while the problem of tuberculosis control in the Southern states is a serious one, it is susceptible of at least partial solution. There is reason for encouragement in the fact that this problem is recognized and that attempts are being made to solve it, and also that the Southern states, despite their financial handicaps, have already made notable progress in other phases of public health work.

IS IT ADVISABLE TO USE COLLAPSE THERAPY IN THE TREATMENT OF TUBERCULOSIS IN THE NEGRO?

It may be said that at present the consensus favors collapse therapy as a therapeutic measure, yet a number of clinicians, notably in the Southern states, still believe that it is contraindicated in the Negro.

Dr. Henry D. Chadwick of Detroit will shortly publish an analysis of the favorable results that he has obtained from the administration of pneumothorax to a large number of Negro patients in the several stages of pulmonary tuberculosis. This contribution should add materially to knowledge on this subject.

As to the effect of this division of opinion on control measures, it undoubtedly is a handicap. There seems little doubt, however, that enough definite evidence will soon be accumulated by Dr. Chadwick and others to put it beyond the realm of controversy.

SYPHILIS AND TUBERCULOSIS

From the studies of Wenger, Ricks and others, it would appear that at least 25 per cent of all rural Southern Negroes have syphilis and there is every reason to believe that urban Negroes have at least as high an incidence. It is therefore of the utmost importance to the Negro race that the role of syphilis in the high tuberculosis death rate be accurately determined.

There still exist two schools of thought as to the relationship between syphilis and tuberculosis. Some authors maintain that there is an antagonism between these two diseases, and inoculation of the tuberculous patient with the syphilitic virus has been suggested as a therapeutic measure. The weight of opinion, however, is that syphilis reduces the natural resistance against tuberculosis, that it is an important predisposing factor, and that its presence renders the prognosis more grave.

With regard to the treatment of the case in which syphilis and tuberculosis are coexistent, the clinician will gain small comfort either from a survey of the literature or from a consultation with his colleagues, there being only one point on which most of the authorities are in agreement, namely, that the iodides should not be used.

Many clinicians advocate the treatment of syphilis with arsenicals, with no qualification as to dosage. Others believe that while the arsenicals should be used the dosage should be materially cut down. Still others

are of the opinion that the arsenicals are contraindicated and that bismuth is the medication of choice. Another group of clinicians believe that they obtain better results if the presence of syphilis is disregarded and do not treat it unless it is causing obvious discomfort.

As long as these questions remain unanswered, control measures will obviously be handicapped. In the event that syphilitic soil is shown to favor the implantation of tuberculosis, additional emphasis must be put on the reduction of the present high incidence of syphilis in the Negro, and it is evident that the present variety of ideas as to therapeutics is not conducive to effective treatment. It is not at all unreasonable to suppose that in answer to these questions lies the possibility of an appreciable reduction in the Negro death rate from tuberculosis.

It is interesting to know that Dr. Aronson of Phipps Institute is now investigating this problem.

CONCLUSIONS

1. At present, the control of tuberculosis, particularly in the Negro, is handicapped by lack of exact knowledge regarding several points of importance.

2. Further research is necessary. Studies such as those now in progress at Phipps Institute and in Tennessee, Alabama and elsewhere should add materially to the present limited knowledge regarding the epidemiologic, pathologic and clinical peculiarities of tuberculosis as it affects the Negro and may aid in the solution of some of the administrative problems involved. Regarding the latter, it is suggested that valuable information may be obtained by studying the various adaptations of administrative procedure that various health departments are making to reach more effectively the Negro population.

3. In view of the important sociological aspect of the problem of tuberculosis among Negroes, this line of approach, which appears to have been relatively neglected, should be further developed, perhaps in conjunction with some of the studies now in progress.

450 Seventh Avenue

ABSTRACT OF DISCUSSION

DR. HORTON R. CASPARIS, Nashville, Tenn.: Dr. Guild brought out that Negro children seem to handle first infections as well as white children. That has been my impression, but Negro adults do badly. The Negro children have nothing to do with their first infections; the Negro adults have everything to do with tuberculosis. There is no specific treatment for tuberculosis and whether or not one gets well depends largely on the individual's more or less sustained cooperation. It would seem, therefore, that the emphasis of control measures should be laid more on prevention. The Negro cannot be depended on to take up that phase of the problem. Reliance must be placed on public health means: official and nonofficial organizations, to go out and find active tuberculosis and to eliminate it as a source of infection. Infected children must be helped either with BCG if that proves satisfactory or with other means.

DR. MARIE PICHIL, Livingston, New York: I cannot refrain from adding a word about a measure that I consider preventive. In New York there is a contraceptive clinic for Negroes. I believe it is the first one in the country. A branch is located in Harlem which is the district in New York having the greatest death rate from tuberculosis. It was felt that in this neighborhood particularly where the infant mortality was so great a proper response from the Negro population was not being obtained. After three years' existence it was found that more white patients than Negroes were coming to the Negro clinic so last month the headquarters were

moved into the New York Urban League Building, which is a settlement house for the advancement of everything relating to Negroes, and the number of Negroes coming to the clinic for such advice has increased. I feel that this is a very necessary public health measure and I believe it is an adjunct to attacking the problem preventing tuberculosis. New York City has a large Negro problem and we are just as concerned there as people are in the South. The various social agencies refer tuberculous or pretuberculous women to our clinic for contraceptive advice as a preventive measure.

DR. EMIL BOGEN, Olive View, Calif.: I have been interested in trying to find why certain races show a higher mortality rate from tuberculosis. I have tried to find out by animal experimentation what will make one strain or family of animals more susceptible to tuberculosis than another. Larger doses of infection will with fair uniformity produce larger amounts of tuberculosis. I have not been able to find any difference by environmental means affecting the development of tuberculosis in animals after they have been infected. I think one has to distinguish, when speaking of environment, between those environmental factors affecting exposure to infection, or the number of germs that the individual receives, and those factors affecting his resistance to the infection. Certainly it can be shown, both by animal experimentation and by epidemiologic studies, that tuberculosis depends greatly on the number of organisms. Cases can be traced from one active case to another. It is much more difficult to show that such things as income or housing conditions or food really affect the development of tuberculosis in different peoples. It is also known that, after tuberculosis develops, the course of the disease depends very much on the treatment and that at the institution with which I am connected we find that the Negroes or those of any other race coming in with early tuberculosis have a very good chance of recovering. I feel that one of the greatest factors responsible for the different mortality rates in different races is the readiness with which the different people come for early treatment.

PROGRESSIVE PSEUDOHYPERTROPHIC MUSCULAR DYSTROPHY

RESULTS OF TREATMENT WITH EPINEPHRINE AND PILOCARPINE

GARRY DEN HOUGH, JR., M.D.
SPRINGFIELD, MASS.

For nearly a century this poorly understood symptom complex has been recognized and has presented a constant challenge to the medical profession. The various therapeutic procedures recommended, including exercises, physical therapy, dietary regulation, calcium and glandular preparations, have all failed to have any appreciable influence in improving the condition or in stopping the gradual relentless progression to complete helplessness.

In 1930, Kure and Okinaka¹ reported improvement in nine cases following the daily administration of epinephrine and pilocarpine. In 1931, I² reported improvement in sixteen cases in which this treatment was used. This paper is based on the present results in these and twenty-two additional cases treated over the period of the last three years at the Shriners Hospital for Crippled Children at Springfield, Mass.

In addition to my own cases I have collected results in fifty-six cases in which this treatment was given

Read before the Section on Orthopedic Surgery at the Eighty-Fourth Annual Session of the American Medical Association, Milwaukee, June 14, 1933.

¹ Kure K. and Okinaka S. Behandlung der Dystrophie musculorum progressiva durch kombinierte Injektionen von Adrenalin und Pilocarpin. *Klin. Wochenschr.* 10:8 (June 21) 1930.
² Hough G. Den Jr. Progressive pseudohypertrophic muscular dystrophy. *J. Surg. 17: 575 (Oct.) 1931.*

elsewhere, thirty-one being from the literature³ and twenty-five from personal communications. According to the various observers, improvement has been noted in thirty-nine, fifteen have been unchanged, while in two the condition has become worse under treatment.

I have used epinephrine-pilocarpine in thirty-eight cases in all stages of the disease, the number of injections varying from twenty-three to over 600. Administration has been by daily hypodermic injections of 0.3 cc of a sterile solution consisting of one part of 1 per cent solution of pilocarpine hydrochloride and two parts of 0.1 per cent (1:1000) epinephrine hydrochloride. The drugs have no incompatibility and may be dispensed together in a rubber capped vaccine bottle and the daily dose removed under aseptic precautions.

Every patient has shown some clinical improvement while taking the treatment. This improvement has been both subjective and objective. It has varied in amount from a slight sense of increased strength with a greater desire to attempt functional activity to apparently complete recovery. In most cases some definite functional improvement could be demonstrated. The improvement was greatest in the least advanced cases.

There have been no additional therapeutic procedures other than general hygienic care, ordinary diet, and normal activity to the limit of the individual capacity. In particular, glycozell has not been used in spite of some encouraging reports, because of my desire to evaluate as accurately as possible the influence of pilocarpine-epinephrine.

It is obviously impossible to eliminate the psychologic factor of a definite course of treatment, particularly in cases in which previously repeatedly hopeless prognoses have been given. The hopefulness and optimistic attitude of the parents very probably has been reflected in the mental condition of the child, and due allowance for this factor must be made. This is particularly true when the improvement has been primarily subjective or when it has been relatively slight.

Fifteen cases have been observed for from one to two years since the last treatment was given, from sixty-nine to 240 injections having been given. In only one case is there any evidence that the progress of the disease has been stopped. The patient, a 13 year old boy with symptoms for eleven years had been confined to a wheel chair for three years. He has apparently not changed during the past year following 240 treatments. Every other case has shown definite progression of the disease, in spite of 200 treatments in one case, 180 in another, and from seventy to ninety in the remainder.

Nineteen patients are still receiving treatment, nine of whom have been under treatment too short a time to present evidence on the question of progress, having received less than 150 injections. Ten patients have received from 150 to 600 injections. Four of these children have shown some loss although still as well as or better than, when the treatment was started. The other six patients have maintained their improvement.

From this evidence I have arrived at the definite conclusion that, although epinephrine-pilocarpine is helpful and of symptomatic benefit, it is not curative.

The treatment must be continued indefinitely and even in spite of continued treatment the condition may progress.

I have attempted to determine the influence of the treatment on the duration of life by an analysis of fifteen fatal cases, ten from my own cases and five from the literature.⁴ As shown in the accompanying table, the four treated cases show a somewhat greater variation of age at time of death, and the average age is about a half year older than in the treated cases. While this suggests a possible lengthening of life, there is not sufficient difference to be of significance.

The remaining problem to be answered is whether this treatment prolongs the period of functional activity. An analysis of ninety-five cases, eighteen of which have been taken from the literature, shows that symptoms are first observed before the age of 2 years in about 12.5 per cent of the cases, from 2 to 4 in 50 per cent and from 5 to 7 in 30 per cent. In only an occasional case were symptoms first noted after 7 years.

Fatal Cases

	Name	Age	Cause of Death	Duration of Disease	Years Unable to Walk
Treated					
D. R.		9	Tetdosis	4	2
Case 5		16	Gente appendicitis	11	3
Case 10		16	Pneumonia	14	7
Case 1		20	Pneumonia	12	7
Average		15.3		10.3	5.3
Untreated					
W. D. (Voshell)		12	Bronchial disease		4
Bishop (1) (Voshell)		12	Whooping cough		4
Bishop (2) (Voshell)		12	Stomach trouble		3
Case 2		1	Pneumonia	10	3
Case 13		1	Pneumonia	8	1
T. D. (Voshell)		1	Unknown		3
Case 6		16	Unknown	10	3
Case 16		16	Influenza and tuberculosis	15	6
W. F. (Voshell)		17	Unknown		7
Case 10		17	Gastro enteritis	15	7
Case 17		17	Pneumonia	16	8
Average		14.7		12.3	4.5

In a few cases the power of locomotion is lost as early as two years after onset, and 35 per cent of the children are unable to walk after 5 years. Most of the remainder (62 per cent) lose their ability to get about between the sixth and the ninth year of the disease. In only an occasional case is gait preserved beyond nine years. Expressed in terms of the child's age, approximately 50 per cent stop walking at the age of 8 to 9 years and 40 per cent at from 10 to 12 years.

The treatment has been carried out in twelve ambulatory and twenty-four nonambulatory cases. In the latter group in spite of the fact that in every case some improvement was observed in no case was gait reestablished. Two of the twelve ambulatory patients have since lost the power to walk at an age of 11 years, after seven and eight years of the disease. Both of these children show a possibly suggestive but probably insignificant increase over the average. The patients who are still ambulatory vary in age from 6 to 13 and average 9.2 years which is slightly beyond the age at which most of the children lose their power to walk.

CONCLUSIONS

I feel justified in making the following conclusions regarding the use of epinephrine and pilocarpine in progressive pseudohypertrophic muscular dystrophy.

1. Daily doses of 0.1 cc of 1 per cent solution of pilocarpine and 0.2 cc of 0.1 per cent epinephrine are of symptomatic benefit in practically all cases.

³ Kure and Okinaka (footnote 1). Voshell, A. F. Progressive Pseudohypertrophic Muscular Dystrophy. South. M. J. 26: 156 (Feb.) 1933. Goralewski, G. and Engel, E. Zur Behandlung der Dystrophia musculorum progressiva mit Adrenalin und Pilocarpin. Deutsche med. Wchnschr. 58: 1169-1170 (July 22) 1932. Leiter, A. Die Adrenalinbehandlung bei progressiver Muskeldystrophie. Monatschr. f. Psychiat. u. Neurol. 81: 289 (Jan.) 1932.

⁴ Voshell (footnote 3).

2 In some of the cases the improvement may be wholly or in part due to the psychologic effect of renewed hope based on a definite course of treatment

3 This improvement has never been sufficient to reestablish gait after the power to walk was lost, but function when present may be markedly improved

4 There is no evidence that this treatment is curative or that it alters the mortality or increases the length of life

5 If treatment is stopped for a period of from one to two years, the gradual increase of disability is again noted

6 Progression may occur while under treatment but apparently the rate of progress is definitely slower than it otherwise would be

7 It is possible that alteration of dosage or the combined use of other methods of therapy may give better results

8 Finally, in spite of the fact that these drugs do not cure the disease, that their benefit is not permanent or as marked as the early reports may have led one to hope, epinephrine-pilocarpine treatment is of sufficient value to justify its continued use in this disease. There is no more excuse for withholding it than there is for not giving insulin in severe diabetes or digitalis to an individual with irreparable cardiac damage. Even these highly valuable therapeutic agents are not curative

ABSTRACT OF DISCUSSION

DR ARTHUR STEINDLER, Iowa City. The interpretation of this condition from the pathologic and etiologic points of view will have to abide its proper time. I believe it was Duchenne de Boulogne who pointed out that this condition is a disease of the muscles and not of the central nervous system and that consequently all methods of treatment that were directed to the central nervous system would come to naught. So when in 1929 Kure and Okuma came out with their pilocarpine-epinephrine method there was some raising of eyebrows. They were able, however, to present a series of twelve cases, six of which improved and two were cured. Dr Hough today presents a series of thirty-eight cases in almost all of which at least temporary improvement was noted. The question of glycine or glycozell treatment ought to be given consideration. When Powers and Teehner brought out their chemical investigation on this subject, they pointed out that the creatine was utilized to the degree of 70 to 80 per cent. Others Gibson and Martin and Brand demonstrated the synthetic power of the organism to utilize creatine. Gibson and Martin accomplished this by feeding gelatin and Brand by feeding glycine, or glycozell. Clinical reports on the use of glycine or glycozell above all the reports of Milhorat and his co-workers describe a certain amount of temporary improvement. The basic idea being that the glycine furnishes the food for the muscles which would otherwise be lost by excessive excretion of creatine it is believed that the treatment should be employed only in those cases in which the initial excess of creatine excretion in the urine and in the muscle tissue disappears after one week of creatine dosage. Voshell reports fourteen cases, nine were improved and five were not improved. His idea was to combine the pilocarpine epinephrine with the glycozell treatment assuming that the glycozell would furnish the food for muscles that would otherwise be lost whereas the epinephrine would provide the stimulation of the autonomic system necessary for the control of creatine metabolism. It is obvious that those cases in which creatine metabolism has been hopelessly upset and is continually affected by an excessive creatine output would not be suitable. I have recently reviewed my own cases, eighty-one in number. Not in a single case was I able to effect an arrest of the condition although all possible methods have been used including epinephrine and glycine.

DR HENRY B. THOMAS, Chicago. At the University of Illinois College of Medicine cases of dystrophy have been admitted for study since 1931. We have in only a few cases, used epinephrine and anterior pituitary, with no noted improvement. We have used glycine with no clinical improvement, also creatine. I believe that any therapy after function is lost will be of no avail. The etiology of the disease must be sought in order that the loss of muscular function may be prevented. We are anxious therefore to experiment on the metabolism of these patients and have our plans laid to proceed along this line. In most cases the diagnosis, as Dr Hough says, is easy. However caution is urged in order to prevent mistakes in diagnosis in obscure cases. We have one case in which there is a coexistence of infantile and muscular dystrophy. We have also one case which we have been calling amyotonia for some time. Closer examination proved it to be an instance of muscular dystrophy of the atrophic form. When 8 months old, the patient contracted scarlet fever. After that his muscles grew gradually weaker and he became more deformed. This case and the one I mentioned before, show a connection with an acute infectious disease. Out of our 634 hospitalized orthopedic cases since 1931 we have included and studied eighteen instances of dystrophy or about 2.75 per cent of our admissions. The pseudohypertrophic form of the disease was presented by 38% per cent, all boys. The ages ranged from 3 to 14. There were thirteen boys and five girls. That is a proportion of 2.6 to 1. Two are brother and sister and the third a maternal cousin. One patient has a sister with a similar condition. Thus in four instances the disturbance was of the familial type. In four of the patients an intercurrent disease, such as pneumonia or whooping cough, proved to aggravate the already existent muscular dystrophy and two thirds per cent have never walked. Fifty per cent walked normally until the age of 3 to 20 years and then motion became gradually impaired. At the present time 22% per cent of them are unable to walk, the remainder have difficulty in walking, especially in climbing up and down stairs. Weakness of the legs since birth was present in 33% per cent. The mental development of these patients has been normal. Well pronounced pseudocontractures were found in 44% per cent. The muscles of the thigh, knee and ankle were usually involved.

DR PHILIP LEWIN, Chicago. I want to express my appreciation of the work that Dr Hough has done on this subject. I began using epinephrine in 1920. In order not to have to make punctures three times a day, I administered hypodermic tablets of $\frac{1}{2000}$ gram dissolved under the tongue which seemed to me a better way than ingestion by mouth, which proved to be worthless. There seems to be an analogy in this condition such as exists between the situations of a coal bin a furnace and a fireman. The fuel may be deficient in quality, quantity or availability. The furnace may be inefficient. The fireman may not have proper ability, strength or industry. The transportation may be wrong so far as speed, direct route, obtainability or detours are concerned. The energy may be at fault so far as quantity, availability and usability are concerned. So far as muscles are concerned the three factors are the efficiency, the ability to store up fuel and the ability to transform the fuel.

When Kure and Okuma in 1930 reported two cures and seven improved cases I thought that it was an addition to the armamentarium but I don't think that Dr Hough's series, Dr Voshell's series or any other series I have studied proves that point. There is undoubtedly something in it. The question seems to revolve about the metabolism. Until the metabolism is thoroughly understood, my method is going to be a hit-or-miss method. There are other forms of treatment such as glycine pituitary extract diet combinations of the Japanese and glycine treatments and blood transfusions. I should like to try the method of giving fetal muscle extract. Milhorat Teehner and Thomas are using from 5 to 15 Gm of glycine a day increasing the output of creatine but it must be continued indefinitely. I think the word improved is misleading because any change from a poor routine may be beneficial. The children that are seen for the first time have been under a poor routine and any change may help them. It must be considered that the course of the disease may have remissions and the cure may be attributed to the therapy.

DR GARRETT N. HOUGH, JR., Springfield, Mass. Of course, this is simply one phase of a complicated subject. I agree that there is a tremendous amount of information to be learned in order to come anywhere near understanding this disease, and I think that eventually this condition will be subdivided into types and groups, probably as distinct entities. What is now classified as progressive pseudohypertrophic muscular dystrophy may represent a number of different conditions. I am convinced that epinephrine and procaine are beneficial although not curative. Dr. Lewin criticizes the use of the word 'improved.' In many of the cases perhaps the change has not been sufficient to warrant the use of this term but my most satisfactory patient, after being under observation for five years last summer passed his test as a life saver and won a quarter-mile swimming race. If after five years of disease, he was able to do that I think he was improved. He is classified however as having shown progress because for three years he represented a complete cure walking with normal gait and taking part in all normal activities. Now he has a definite limp, walking with a side-to-side sway.

Clinical Notes, Suggestions and New Instruments

CARCINOMA OF BARTHOLIN'S GLAND

REPORT OF TWO CASES

HYMAN STRAUSS, M.D., BROOKLYN

Primary carcinoma of Bartholin's gland is rare. A review of the world's literature by Harer in 1933 revealed only thirty cases recorded, not all of which in his opinion were authenticated. Nothing definite is known about the etiology. Falls says that chronic inflammation has been present in a considerable number of the cases reported. In only one case was there a definite history of gonorrhea and syphilis. Bilateral inflammation of the gland was described in only one case. The lesion has been found in unmarried women but not in virgins. The youngest patient was 28 and the oldest 91 while the average age was over 50 years.

Diagnosis is usually made postoperatively. It is most frequently confused when associated with chronic infection with abscess formation. Syphilis, contrary to gonorrhea, rarely attacks this gland. Chaneroid and granuloma inguinale affecting Bartholin's gland have not been reported. Primary tuberculosis is rare there being only three cases reported. Viet found reports of three cases of sarcoma of this gland. The prognosis, according to Kelly, is usually fatal because of late discovery or incomplete operation. In the cases reported one patient survived for three and another for six years free from recurrence. Metastasis occurs in the inguinal lymph glands quite early.

The treatment is primarily surgical. However, at Radiumhemmet, in Stockholm electrocoagulation of the tumor and radiotherapy have been used with considerable success. Howard Kelly advises endothermic vulvectomy and electrocoagulation of the glands *in situ*. Trussig, who has made a study over a period of years insists that radical vulvectomy and a complete bilateral Basset operation is the only procedure that has stood the test of time. If the lesion is early or the risk slight, he performs this operation in one stage; otherwise it is done in two stages with an interval of a few weeks. He has not been satisfied merely with excision of the vulva and irradiation of the regional lymph nodes.

REPORT OF CASES

CASE 1—Mrs. C. M., aged 61, white, an American, was admitted to the gynecologic clinic of the Brooklyn Cancer Institute Jan. 15, 1932, with swelling of the right side of the vulva, which had been noticed for a few months. At first the swelling was small, firm and painless. In spite of hot compresses and other remedies applied to the lesion, it increased

in size. She was referred to the clinic by her physician. There was nothing of interest in her previous history. She was a tertigravida and a tertipara. The menopause occurred at 34. During the year before admittance, the patient had frequent spells of hemoptysis.

On admittance the patient was emaciated, weighing 74 pounds (33.6 kg.). Examination of the genitalia showed a mass measuring 8 by 4 by 3 cm., involving the right labium majus and almost occluding the introitus. The tumefaction was firm, smooth, not tender and with no area of fluctuation. The mass was not fixed to the underlying tissues but was adherent to the overlying skin, which was reddened. The inguinal nodes were not appreciably enlarged. Otherwise the genital organs presented no abnormalities. The Wassermann test was negative and the sputum was repeatedly negative for tubercle bacilli.

Examination of the blood revealed red blood corpuscles, 3,680,000 with no early forms, hemoglobin 90 per cent, white blood corpuscles, 18,200, polymorphonuclears 84 per cent, lymphocytes, 11 per cent, monocytes, 4 per cent, eosinophils 1 per cent.

A roentgenogram of the chest showed no cavities or consolidation but veiling over both apical fields, an evidence of a thickened pleura. The lung root densities were not abnormal in size. There was some calcium deposit.

A diagnosis of carcinoma of Bartholin's gland was made and operation was performed January 28. The involved area was completely excised. The pathologic diagnosis was anaplastic carcinoma of Bartholin's gland.

Interstitial radium therapy was administered to the right labium at the site of the incision, March 9. Two tubes of 9 mc. each of radon filtered through 0.5 mm. of platinum were inserted and allowed to remain in place until a dose of 1,200 millieury hours was delivered. In May, a course of high voltage roentgen therapy was administered to the pelvis and perineum five portals being used. A total of 6,450 roentgens was administered over a period of twenty-one days.

The patient was seen in the follow-up clinic from time to time. In January, 1933, a small erosion was noted at the site of the operative scar. Further radiation was prescribed. This was given by applying two gold filtered radon seeds of 1 mc. content each delivering a total dosage of 266 mc. hours. Since then the lesion has remained completely healed.

CASE 2—Mrs. M. L., aged 48, white American, admitted Feb. 16, 1933, to the gynecologic service of Kings County Hospital, service of Dr. H. M. Mills, complained of a lump in the vagina and a vaginal discharge. Two years prior to admission, the patient noted a small mass slowly increasing in size. Four months before admission, the mass grew rapidly and a whitish to bloody vaginal discharge occurred. One month before admission, bleeding from the lesion and vaginal pain radiating to the right thigh set in.

The pain was sharp and stabbing. She lost 5 pounds (2.3 kg.) in two months. She was a primigravida in 1909 and there was a miscarriage, after which complications developed necessitating a hysterectomy. In 1929 the patient had a cholecystostomy, which was later followed by a cholecystectomy.

The patient was obese and did not appear acutely ill. Rectal examination was negative. The right labium majus was enlarged by a mass about the size of a walnut which protruded over the introitus and practically occluded the vagina but did not extend to the inguinal or perianal areas. It was irregular in outline, much indurated and exquisitely tender. The overlying skin was adherent, swollen, reddened, edematous and beginning to ulcerate. The mass was slightly fixed to the underlying tissues. There was an ulcerated area about 25 mm. in diameter at the exit of the duct, which extended three-fourths inch along the vaginal wall. This area bled readily. The vagina otherwise appeared normal. The uterus presented no pathologic changes, the adnexa were not palpable. A brownish discharge was present. The inguinal lymph glands were not palpable. Roentgen examination of the chest revealed no pathologic changes.

The blood Wassermann reaction was negative. Chemical examination of the blood revealed sugar, 114 mg. per hundred cubic centimeters; creatinine, 1.25; urea, 35. The blood count revealed red blood corpuscles, 4,192,000; no early forms; hemoglobin, 85 per cent; white blood corpuscles, 5,200; poly-

From the Department of Gynecology, Kings County Hospital, Dr. H. M. Mills, Director, and the Department of Radiology, Division of Cancer, Dr. I. I. Kaplan, Director.

morphonuclears, 61 per cent, lymphocytes, 36 per cent, large mononuclears, 3 per cent

Examination of a catheterized specimen of urine revealed a specific gravity of 1.021, acid, no sugar, a trace of albumin, many fine granular casts, many leukocytes, an occasional red blood corpuscle

A diagnosis of carcinoma of Bartholin's gland having been made, a radical vulvectomy was done, February 24. The wound healed slowly because of secondary infection. Six weeks after the vulval wound had healed, a bilateral Bassett dissection of the inguinal and femoral glands was done. The pathologic diagnosis made by Dr. Hala was squamous cell carcinoma, but there was no evidence of metastasis in the lymph glands removed. The convalescence was uneventful. The patient when last seen, June 30, 1933, was free from symptoms and there was no evidence of recurrence

A PATIENT SENSITIZED TO AN ART GUM ERASER

JUNE ADKINSON, A.M. AND I. CHANDLER WALKER, M.D. BOSTON

Although this case is not of widespread interest to the community at large, it does concern those who use extensively art gum erasers, such as artists, art students, architects and masseurs

A woman, aged 25, normal with the exception of a defect of vision which is corrected by wearing glasses, daily used a binocular microscope for from one to five hours a day without eyestrain. Recently she began to draw from the microscopic field for several hours at night and often for all day on Sunday.

After a short time the patient noticed a persistent itching of the eyes and edema of the eyelids, which could be relieved temporarily by rubbing the eyes with her hands. Later on, even when she did not touch the drawing materials for several days, the swelling and redness of the eyelids would persist and there was a marked increase of the symptoms whenever the drawing was resumed. Still later there was constant redness, rawness and itching at the corners of the mouth and the usual symptoms of a slight cold. A marked rhinitis and a sensation of soreness in the throat occurred whenever the patient was exposed to the drawing materials. This condition continued for seven weeks.

Fearing that the additional strain on the eyes from the prolonged periods of drawing was injuring her sight, the patient consulted an ophthalmologist, who found that her vision was unchanged, in spite of the excessive use of the eyes. From the history and the appearance of the eyelids and the corners of the mouth, the ophthalmologist felt that the condition was allergic in nature and was caused by some substance to which she was only recently exposed. Skin tests were advised with toilet preparations, drawing materials and other substances such as clothing and gloves.

Since her toilet preparations were of the same brand that she had used for years and since the only change in her environment and occupation was the drawing and furthermore because the symptoms which started soon after she began to draw, were aggravated whenever she used the drawing materials for a long time and were relieved when she was not exposed to them, the patient thought that the paper, the ordinary rubber eraser, the soft viscous art gum eraser or a cement used for mounting pictures was probably the offending factor.

The drawing materials were avoided for several days until the eyelids were only a little swollen and there was very slight itching. When the patient was nearly normal again skin tests by the scratch method were made on the left forearm with toilet preparations, with rubber eraser, soft art gum eraser, picture mounting cement and drawing paper. A very small amount or piece of each substance was placed on a slight cut made with a sharp scalpel penetrating the cuticle but not drawing blood. A drop of tenth normal sodium hydroxide was placed on each scratch to dissolve the fragment of material and allowed to soak for fifteen minutes after which the scratches were gently wiped off and the reactions were compared with a control scratch on which only a drop of tenth normal sodium hydroxide had been placed. The tests with the toilet prepara-

tions were entirely negative, the tests with the rubber eraser and the drawing paper were slightly red, but the test with the art gum eraser produced an urticarial wheal 0.75 cm in diameter surrounded by a flushed area about 2 cm in diameter.

Although the eyelids were only slightly itching and swollen before the skin tests were made, on the following morning and apparently as a result of the skin tests, both eyelids were badly swollen and the itching was severe. The swelling disappeared rapidly and the patient was fairly comfortable for several days or until the following Sunday, when she spent several hours drawing with the same materials. After this exposure the swelling and itching of the eyes reappeared and continued for about twenty-four hours. The corners of the mouth were not affected after the tests or after this prolonged exposure to the drawing materials, probably because the patient, who had had the habit of holding her pencil contaminated of course with eraser and paper dust, in her mouth while erasing was very careful to avoid touching her face with her hands and the drawing materials. During the five days of avoidance of drawing, the eyelids became almost normal.

On the fifth day after the last exposure, a more extensive series of scratch tests was made on the other forearm with foods, pollens, animal hairs and feathers, all of which gave entirely negative reactions. In addition, retests were made with solutions of the drawing materials. The solution of rubber eraser gave a negative reaction, the solutions of cement and of drawing paper gave a slight erythema, but the solution of art gum eraser gave a definite itching raised area about 1 cm in diameter surrounded by a flush about 3 cm in diameter.

About two hours after the second series of tests was made, the left cheek began to redden and burn, and an hour later, about 5 o'clock, a definite urticarial wheal appeared on the left cheek. By 8 o'clock there was itching and marked swelling of both eyelids as severe as the symptoms produced by several hours' use of the drawing materials to which the patient had not been exposed for five days. Application of fresh menthol ointment gave sufficient relief for her to go to sleep normally.

About 2 o'clock in the morning the patient was awakened by a very severe burning sensation in both eyes. The eyelids were so edematous that the left eye could hardly be forced open. The lips were stiff, swollen, protruding and hot, and there was a severe rhinitis. The throat was not affected, but the patient was frightened and in mental distress. The application of boric acid solution gave no relief, but acetylsalicylic acid tablets and the application of fresh menthol ointment relieved the symptoms in a short time. On the following morning, although the edema was somewhat reduced and the itching had subsided, the eyelids were still badly swollen and two or three hive-like areas appeared on the cheek and neck. After the application of menthol ointment at 11 o'clock, the facial swelling receded rapidly.

Examination of the test area on the arm showed that all scratches were normal where the tests had been negative on the previous day. The scratches to which the solutions of picture mounting cement and rubber eraser had been applied were negative and the scratch on which a solution of drawing paper was tested showed a slight redness, but the scratch on which the art gum eraser solution had been placed showed redness and erosion about 0.75 cm in diameter.

In order that the drawing, which was an unaccustomed occupation, might be finished a plan was made for the patient to protect herself from exposure to the dust of art gum eraser and drawing paper dust by smearing her face heavily with ointment of rose water, by wearing a damp gauze mask over her mouth and nose and by protecting her eyes with glasses. With these precautions the patient was able to continue her drawing for two and one-half hours on one day, five hours on another and longer periods with no return of the itching and edema. Any use of the art gum for erasing without the facial mask caused a beginning of the itching and swelling of the eyelids, but erasing done with the ordinary rubber eraser produced no discomfort even without the mask.

A slight return of the irritation of the eyelids was noticed whenever the patient sat in the room where the drawings had been made. After a thorough dusting of the furniture and of the work table with a damp cloth and beating of the rug out door the patient experienced no further trouble in the room.

Still later, when the patient visited the store where the art gum was purchased, she stood near a counter on which were exposed brick-shaped large pieces of the art gum material to be used on their hands by masseurs in rubbing patients for weight reduction. The odor or dust of the material was so abundant that the patient felt an immediate effect in her eyes and throat and she retired for relief to the sidewalk until her purchases were ready.

Council on Pharmacy and Chemistry

PYRIDIUM OMITTED FROM N N R

THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORTS
PAUL NICHOLAS LEECH Secretary

Pyridium¹ is the monohydrochloride of an azo dye of the pyridine series, phenylazo-*o*-*a*-diamino pyridine. It is marketed by Merck & Co. Inc. in the form of a 1 per cent aqueous solution, a 10 per cent ointment, and tablets containing 0.1 Gm. The firm presented the product for consideration of the Council in 1928, proposing it for use mainly as a urinary antiseptic. The A M A Chemical Laboratory examined the product and evaluated suitable standards of stability and purity, as well as corroborating the claimed composition.²

The firm's original presentation of Pyridium was accompanied by four circulars containing claims and excerpts from a pamphlet by Iwan I. Ostromislensky, entitled "The Scientific Basis of Chemotherapy." Ostromislensky, who originated Pyridium in 1912, appears to have used the drug first in Russia in 1917 and brought it with him to this country for clinical trials and manufacture about 1924. The base apparently was first described by Tschitchibabin and Zerda. Most of Ostromislensky's book on chemotherapy is concerned with an account of Pyridium. This evidence was judged to be unconvincing. The Council declared Pyridium unacceptable in July 1928, and adopted for publication a statement of its consideration. A request by Merck & Co., Inc., for postponement of publication of this report was granted.

Additional evidence was presented by the firm in April, 1929, and further postponement granted. A recommendation to accept Pyridium in December, 1929, was not adopted because it was desired to obtain opinions on the evidence from critical genito-urinary surgeons. In March, 1930, opinions on the value of the evidence for Pyridium were expressed for the benefit of the Council by two prominent genito-urinary surgeons, consultants of the Council, who considered the evidence submitted to be insufficient to support the claims but did not advise rejection of the product. Further postponement of action by the Council was decided on.

While these negotiations with the Council were being carried on by Merck and Co., the Mallinckrodt Chemical Works began to push the sale of Mallophone and E. R. Squibb and Sons began to exploit Serenum, Mallophone (for which the firm has indicated willingness to substitute the nonproprietary name Azophene) is identical with Pyridium, as shown by an investigation in the A M A Chemical Laboratory, while Serenum is an azo dye of a similar type. The firms of Mallinckrodt and Squibb did not submit their products to the Council at that time, and Merck and Co. appeared to be suffering a loss through its attempt to cooperate with the Council. A recommendation that Pyridium be accepted for one year was adopted in April 1930. The referee stated in the discussion of this action that both genito-urinary consultants favored acceptance. After discussion of the evidence the Council announced acceptance of the product.³

Pyridium was retained in New and Nonofficial Remedies during 1931. On the basis of new evidence presented by the firm, the Council's referee, in May of that year, obtained an opinion from one of the consultants that Pyridium still gave promise of therapeutic usefulness, but the other consultant was not convinced by the new evidence. This evidence was chiefly voluminous unpublished reports submitted by the firm. The Council voted to accept Pyridium for another one year period, although at the time a member of the Council stated that he feared that in a few years pyridium will join the ranks of discarded urinary antiseptics.

A new referee was then assigned the task of reviewing the old and new evidence on Pyridium. He recommended acceptance of Pyridium under severely limited claims, and in November, 1931, the Council adopted this recommendation. The conditions specified for this acceptance considerably restricted the claims for Pyridium. The restrictions were, in brief, that the firm should not emphasize the tissue-penetrating property of Pyridium, should limit claims for efficacy of the drug in the treatment of prostatitis and pyelitis, should omit all claims that the drug protects the tissue cells against bacterial toxins and stimulates body defense regeneration and repair of tissues, and should refer explicitly to possible gastro-intestinal disturbances sometimes produced by the drug. The firm agreed to abide by these requirements and in later correspondence with the referee, through the Secretary, agreed to drop its claim that Pyridium taken by mouth gives a bactericidal power to the urine. An antibacterial or bacteriostatic action of urine containing excreted Pyridium seemed to have been established according to the evidence reviewed at that time.

During 1929 bacteriologic reports had been received from the Lederle Laboratories, the Pease Laboratories, the Gradow Laboratories and Professor Prescott of the Massachusetts Institute of Technology. All of these indicated that Pyridium in various solutions had bactericidal and bacteriostatic effects on *B. coli* and *Staphylococcus aureus*. They favorably impressed the previous referee. They are in harmony with other similar laboratory examinations considered by the Council. They lacked data on the antiseptic property of urine containing excreted Pyridium and clinical reports also were lacking.

Finally, the firm has stated that it has numerous letters from physicians testifying to the efficiency of Pyridium. These have not been submitted. They could not be considered as having any definite value as evidence. The firm sent a reference to a report on Pyridium by Szancer in the *Pharmazeutische Nachrichten* Warschau 1930. Przemysl. This journal not being available to the referee he has not examined the report. Other expressions of opinion unfavorable to Pyridium have been made by Dr. Keyes⁴ and in the Queries and Minor Notes section of THE JOURNAL.⁵

In July, 1932 Merck & Co. Inc., submitted the text of a proposed advertisement of Pyridium as a "first aid" antiseptic, indicating its intention to exploit the product to the public as an "effective" antiseptic for local use on cuts, wounds and abrasions. The referee replied through the Secretary that he did not have sufficient evidence to justify acceptance of Pyridium for these purposes and asked the firm to submit the evidence before proceeding on this plan of exploitation. The firm decided to abandon this plan.

A review of the firm's advertising convinced the Council's referee that it has been restrained within the specifications of the Council as far as the use of words is concerned. The referee believes that Merck & Co. Inc., has made a faithful and expensive effort to comply with the regulations of the Council.

The Council's referee presented the following summary and the conclusions which he has drawn from his consideration of the reports on Pyridium. An annotated list of the papers and reports studied by the referee (except where otherwise noted) appears as the first addendum to this report.

¹ Pyridium in aqueous solution has bactericidal and bacteriostatic properties. These effects are less against *B. coli* than on *Staphylococcus aureus*. These effects are reduced by urine and liquids containing complex organic substances.

⁴ Keyes Urology 1928 p 111.

⁵ Pyelitis After Otitis Media J A M A 99 584 (Aug 13) 1932

¹ Azophene (formerly Mallophone) marketed by the Mallinckrodt Chemical Works is identical with Pyridium. The Council's report rejecting Azophene appears in this issue of THE JOURNAL. A somewhat similar product, Niazol, also recommended for use as a urinary antiseptic is marketed by the Schering Corporation. The Council's report rejecting this product appeared in THE JOURNAL June 3 1933 p 1767. Serenum does not stand accepted.

² Collins G W Chemical Examination of Pyridium and Mallophone J Am Pharm A 20 455 1931.

³ Pyridium J A M A 95 34 (July 5) 1930.

2 Urine secreted after oral administration of Pyridium has no bactericidal effect on *B. coli* and a negligible bacteriostatic action. Occasionally urine containing excreted Pyridium may be bactericidal and bacteriostatic against *Staphylococcus aureus*. The lack of these effects may be due to inability practically to obtain a sufficiently high concentration of the substance in the secreted urine or to a change in the substance in its passage through the body. Since Pyridium does not cause the secretion of an antiseptic urine it cannot be sustained as a urinary antiseptic.

3 Numerous clinical reports on Pyridium therapy in infections of the urinary tract are open to doubt and do not present convincing evidence. Evidence denying its efficacy is accumulating in published reports and in less formal expressions of competent urologists. During eight years of trial Pyridium has not become established as a useful remedy.

4 The earlier claims that the drug detoxified bacterial poisons aided the defenses of the body and stimulated tissue repair have not been supported and have been withdrawn.

5 No convincing evidence has been presented that Pyridium is a useful antiseptic for application to infected wounds either in treatment or as a prophylactic.

6 Penetration of tissues especially mucous membranes has been demonstrated. But there is no experimental or clinical proof that the amount and character of the compound in the tissues and mucous membranes are such as to kill bacteria or hinder their growth.

The Council's referee recommended, therefore, that the acceptance of Pyridium be revoked at once and that the product be declared unacceptable for continued inclusion in New and Non-official Remedies as a local, general or urinary antiseptic because claims for its therapeutic usefulness are not warranted by the accumulated evidence. The Council adopted the referee's report and authorized publication of this statement of the Council's consideration of Pyridium.

When the foregoing report was submitted to Merck & Co., Inc., the firm replied in a carefully prepared and well documented brief which required further consideration by the Council. The thesis of the firm's brief was that Pyridium has become established as a useful remedy. To uphold this, the firm offered (a) informal reports from physicians including "approximately 30,000 additional reports as well as a number of special reports of both controlled and uncontrolled clinical experience" received by the firm since December, 1928, and photostat copies of forty one letters from "leading authorities in the United States giving expression to the fact that they find Pyridium useful in their particular fields." The firm offered to tabulate the reports referred to but the Council considered the submitting of such a tabulation unnecessary, since they no doubt provide a type of evidence which has been abundantly supplied in connection with almost every sort of drug and has not been a dependable guide to wise and fair action on the part of the Council. As for the forty one letters, they are, properly, brief statements of opinion in reply to an inquiry from the firm. All except two are favorable to Pyridium. These letters were not intended to supply evidence in the sense of detailed observation.

The firm in addition presented (b) new evidence in the form of published reports. The Council's referee analyzed these as indicated in the second section of the addenda to this statement.

In its brief the firm pointed out technical faults and omissions of procedure in some of the laboratory investigations which had been cited in the former report as affording evidence unfavorable to Pyridium. The Council's referee was aware of these deficiencies when he reviewed the papers in question. It is correct as pointed out by the firm that the single 0.4 Gm dose administered by Davis and Sharpe⁶ is less than the repeated 0.6 Gm dose recommended by the firm. In the opinion of the Council's referee however the experimental evidence prevented justified the conclusions drawn from the work.

The firm presented a program of further research on Pyridium preceding it with the statement. From our previous correspondence with the Council we recognized the need for additional research on Pyridium. The program of research outlined by the firm appeared to the Council's referee to be comprehensive and admirable. The referee had no other suggestion to offer on this program. It is obvious that the results of the investigations will be awaited with interest and may afford a basis for renewed consideration of the drug. The present report of the Council is of course made without prejudice to future reconsideration of Pyridium.

The firm requested the reacceptance of Pyridium, expressing the hope that "the Council will find sufficient basis for formulating conditions upon which to grant a continuance of the acceptance of Pyridium." After careful consideration of the material submitted by the firm, the Council concluded that, while Pyridium may have some value as an adjuvant in the treatment of genito-urinary infections, this is a very indefinite, indeterminable property of a substance recommended for its positive value as a urinary antiseptic.

The Council decided that there does not appear to be sufficient basis for the formulation of conditions on which to grant a reacceptance of Pyridium and voted to reaffirm its previous decision to omit Pyridium from New and Nonofficial Remedies and authorize publication of the foregoing statement of its consideration.

ADDENDA

I Annotated List of Published Articles and Other Reports Consulted in 1932

An annotated list of the papers and reports studied by the present referee (except where otherwise noted) is as follows:

- 1 Ostromslensky I. Scientific Basis of Chemotherapy 1926 Book. Bacteriologic and clinical data unconvincing.
- 2 Belfeld W. T. and Rulnick H. C. Observations on the Physiology and Therapy of the Seminal Duct. J. A. M. A. 89:2104 (Dec. 17) 1927. Ingested and injected Pyridium excreted in seminal ducts. Spermatozoa stained. No therapeutic use of Pyridium reported here.
- 3 Hirschfelder A. D. and Decherd G. M. Inhibiting Effects of Lipoids upon Action of Antiseptics. Proc. Soc. Exper. Biol. & Med. 25:824-826 1928. Bacteriostatic tests with *B. coli* and *Staphylococcus aureus* exposed for three hours to Pyridium in salt solution and in solution with lipoids. Lipoids reduced the effect. Pyridium less bacteriostatic than acriflavine and mercuric chloride.
- 4 Pugh W. S. Infections of the Urinary Tract. The Use of Urinary Antiseptics. A. The Pylonephritides. M. J. & Rec. 127:414-416 (April 18) 1928. Twenty cases reported in a summary table. Pyridium regarded as helpful in cases without anatomical defect.
- 5 Meyers J. L. The Elimination of Dyes by the Uterine Mucosa. J. Lab. & Clin. Med. 14:930-939 1928. Intravenously injected Pyridium stained the uterine mucosa of dogs. No data on concentration of dye in the mucosa. No clinical tests.
- 6 Wolburst A. L. Oral Therapy in the Treatment of Gonorrhea and Other Urinary Infections. M. J. & Rec. 128:272-273 (Sept. 19) 1928. Reports personal experience with Pyridium as an adjuvant to local treatment. A preliminary report without much evidence presented concluding that Pyridium is a promising therapeutic agent.
- 7 Bernhardt E. Neuere Farbstoffbehandlung (mit Pyridium) bei Uleus molle und Gonorrhoe. Dermat. Ztschr. 55:397-402 1929. Report on about twenty-one cases cured by Pyridium. Regards Pyridium as unentbehrlich. Acute gonorrhea cured in fourteen days by oral administration. Observations seem to have been carefully made. Many details not presented. Not convincing but of some value in favor of the drug.
- 8 Pugh W. S. Infections of the Urinary Tract. Prostatic Infections. M. J. & Rec. 129:155-157 (Feb. 6) 1929. Oral administration of Pyridium plus massage greatly reduces the period of treatment of prostatitis. Good results claimed in acute posterior urethritis of gonococcal origin in salpingitis and in vulvovaginitis of children. No data given.
- 9 Stern R. Klinische Erfahrungen mit Pyridium, einem neuen Harnantisepticum. Klin. Wchnschr. 8:1358-1359 (July 16) 1929. Report of three or four cases.
- 10 Stickl O. Ztschr. f. Desinfekt. u. Conditsw. 21:33-37 (Feb.) 1929. Test tube bactericidal and bacteriostatic tests of solutions of Pyridium in salt solution and bouillon. Action decreased by presence of bouillon. In salt solution 1:1000 Pyridium killed *Staphylococcus aureus* at once. Bacteriostatic action in dilution of 1:10,000 at least. Much less effect on *B. typhosus* and *B. proteus* (1:1000 did not kill). Bacteriostatic action slight. Even less effect on *B. anthracis*. Bouillon reduced action as compared with salt. Activity of Pyridium considerably less than that of a 1:1000 solution of corrosive mercuric chloride.
- 11 Thomas B. A. and Wang I. K. Studies on the Comparative Clinical Values of So-Called Urinary Antiseptics. J. Urol. 22:41-1929. Pyridium in solution in water was bacteriostatic for *Staphylococcus aureus* 1:32,000 and for *B. coli* 1:500 bactericidal for *Staphylococcus aureus* 1:10,000 and for *B. coli* 1:100. In solution in urine it was bacteriostatic for *Staphylococcus aureus* 1:1,000 and for *B. coli* 1:400. It was bactericidal for *Staphylococcus aureus* 1:300 and for *B. coli* 1:50. Sixty samples of urine containing the excreted dye after oral administration were studied. Six samples had some bacteriostatic action against *Staphylococcus aureus* and none for *B. coli*. None of the samples were bactericidal against either of the two organisms.
- 12 Walther H. W. E. Clinical Application of Urinary Antiseptics. South. M. J. 22:161-166 (Feb.) 1929. Tabulated report of fifty cases elected from a series of 200 cases of various sorts of urinary tract infection. Very favorable to Pyridium.
- 13 Baerensen A. Zur Behandlung der Cystitis mit Pyridium. Zentralbl. f. Bakt. 54:242-243 (Oct. 4) 1910. Shows that 1:1000 solution of Pyridium in water killed *B. coli* in thirty minutes and 1:10,000 killed in twenty-four hours. Urine containing

⁶ Davis, F. L. and Sharpe, J. C. Urinary Antiseptics. J. A. M. A. 93:10 (Dec. 17) 1927. (See also addendum 3.)

excreted Pyridium was not bactericidal and only slightly bacteriostatic for *B. coli*. Argument presented for Pyridium as an aid to the defenses of the body. Reports briefly result in about forty two cases of cystitis. Ranks Pyridium high as a urinary antiseptic. Very few data given.

14 Furniss H. D. Office Treatment of Urinary Tract in Women. *Am J Surg* 8:289-291 (Feb.) 1930. Pyridium thought to be effective in conjunction with other therapeutic measures.

15 Koster O. Bakteriologische und klinische Versuche mit Pyridium. *München med. Wchnschr.* 77:1013-1016 (June 13) 1930. States that a 1:2000 concentration of Pyridium can be reached in urine after ingestion of 0.6 Gm. daily. Maximum concentration reached on the second day. No killing of organisms in 300 minutes in a 1:500 concentration of Pyridium excreted in urine, but some bacteriostatic action. Brief case reports on treatment of cystitis. Results favorable to Pyridium.

16 Mercier O. Le traitement des infections urinaires par les sels de pyridine. *L'Union med. du Canada* 59:739-742 1930. Pyridium not referred to by name but was evidently the substance used. The firm directed the referee's attention to this paper. Results of trials over a period of three years in 187 cases reported with very brief comments. No cure in any of 22 cases of acute gonorrhea or 26 cases of chronic gonorrhea. Complete cure of 38 per cent of 29 cases of cystitis. Cures of acute pyelitis in seven to nine days. Brilliant results when infection was due to *Staphylococcus aureus*. Chronic pyelitis cured in eight to ten to eighty six days. Considerable improvement in other cases. Failures in some. Pyridium an absolute failure in treatment of gonorrhea but possibly beneficial in treatment of cystitis and pyelitis.

17 Neuburger J. Pyridium ein neues Harndesinfizans. *München med. Wchnschr.* 77:1016-1017 1930. Brief comments on good results in treatment of cystitis and pyelitis.

18 Orłowski. Pyridium bei Soringen im Urogenitaltraktus. *Ztschr. f. Urol.* 24:838-842 1930. Brief reports on about forty five cases of prostatitis, cystitis, mostly chronic and refractory to other treatment. Miraculous results in a number of cases. Pyridium a useful sedative. A man who could not drink beer at night without wetting the bed was cured of this nocturnal enuresis by taking Pyridium and securing diuresis before he went to sleep. Good results claimed in treatment of gonorrhea. Says that Pyridium refutes Neisser's aphorism that every case of gonorrhea gets well—except the first. There is a note by the editor (Dr. Casper) at the end of this paper placed there with the consent of Orłowski stating that Pyridium was no better than other urinary antiseptics.

19 Ravich A. and Blaustein L. Study of 100 Suprapubic Prostaterectomies. *Long Island M. J.* 24:425-429 (Aug.) 1930. Pyridium used as part of preoperative preparation. Good results claimed but there was no way of judging the effect of Pyridium among many other unknown factors.

20 Wolbarst A. L. The Study of a New Antiseptic in Urinary Infections. *Internat. J. Med. & Surg.* 43:499-502 1930. Favorable to Pyridium but no new evidence presented. Reference to good results in use of Pyridium as an adjuvant to other methods.

21 Wolbarst A. I. Gonococcal Infection in the Male. 1930. Book. Pyridium decidedly effective as an adjuvant to local treatment of gonorrhea and decidedly effective as an adjuvant to instrumental methods in pyelitis and other upper tract infections of *Staphylococcus* and *B. coli* origin. Largely a quotation from Dr. Wolbarst's previous paper.

22 Weil H. Ueber die Anwendung des Pyridiums bei Gonorrhoe. *Therap. d. Gegenw.* 71:455-459 (Oct.) 1930. Short reports on about 115 cases of gonorrhea both acute and with complications. Pyridium an absolute failure here. No favorable results of treatment of *B. coli* cystitis with Pyridium. It presents strong evidence against Pyridium.

23 David C. Trois nouveaux antiseptiques urinaires. *Hopital* 19:282-284 (April) 1930. Pyridium cannot be used to replace local treatment. Mucosa of uterine cervix tinged yellow after oral ingestion of Pyridium. Not favorable to Pyridium.

24 Deakin R. J. The Efficacy of Pyridium in Gonococcal Urethritis. *Missouri State M. A.* 28:123-125 (March) 1931. Average duration of treatment 6 cases local treatment alone 109 days. 17 cases local treatment plus Pyridium 79 days. Selected cases. Conclusion reached that Pyridium aided treatment. At best this is favorable to Pyridium as an adjuvant.

25 Goerner A. and Haley F. I. A Study of the Antibacterial Properties of Pyridium. *Urinary Antiseptic J. Lab. & Clin. Med.* 16:957-966 (July) 1931. Bactericidal and bacteriostatic tests of solutions of Pyridium in both and urine. Average bactericidal power 1:5000 and average bacteriostatic power 1:8000. Bactericidal values higher than those obtained by others. Increased time of contact of Pyridium and bacteria accounts for this. This paper submitted by firm in typewritten form in 1931. Review shows that it is not strong laboratory evidence in favor of Pyridium and does not give any clinical information.

26 van den Bergh A. A. H. and Revers F. E. Sulfhemoglobin nach Gebrauch von Pyridium. *Deutsche med. Wchnschr.* 57:706-708. Sulfhemoglobin formed when patients take Pyridium and magnesium sulphate at the same time. No clinical data given but reference made to studies by Revers and statement made that Pyridium is very useful for treatment of cystitis, pyelitis and prostatitis.

27 Mason L. M. Pyridium Therapy in Genito-Urinary Diseases. *Virginia M. Monthly* 58:190-194 (June) 1931. Report on a two months clinical trial of Pyridium in treatment of prostatitis, pyelitis, pyelonephritis, gonorrhea and chancroids. Number of cases not recorded here. Brief abstracts of fourteen case records. Combination of therapeutic measures used in nearly all. No clear evidence in favor of Pyridium but author regards Pyridium as decidedly effective as an adjuvant to instrumental measures in urinary infections.

28 Muller F. Erfahrung mit Pyridium bei septischer Erkrankung. *München med. Wchnschr.* 78:233-235 1931. Remarkably good results in treatment of peritonitis, appendicitis, perimetritis, pyosalpinx, postscarlatinal sepsis, puerperal infection with pelvic abscess, rheumatic fever (?). Single case of each reported. Surgery used in most of the cases but not in all. The series is too small and uncontrolled to be worth much except as an indication of a possibility.

29 Schofield F. S. Typewritten reports preliminary and supplementary on Clinical Observations on Pyridium. 1931. Work done at University of Pennsylvania Urological Department. Tests made at request of Merck & Co. As control used previous study of 2000 cases of gonorrhea treated at that clinic. Average duration of treatment by copaiba by mouth and irrigation with potassium permanganate was thirteen weeks. These reports show twenty cases of gonorrhea greatly improved in from four to six weeks and eleven other cases of various urinary tract infections improved by Pyridium. Dr. Schofield does not state his opinion and does not seem to have published these very good results. This paper published later.

30 Tatum W. B. Typewritten report sent in by the firm. "A Report of the Value of Pyridium in Forty Eight Cases of Urinary Infection." 1931. Work done at the instigation of Merck & Co. Varying good results in many types of urinary tract infections. Elaborately documented. Long case report. Author concludes that Pyridium has greatly benefited all cases treated and it has a definite place in urologic therapy as an antiseptic. This report is very difficult to summarize. It made a favorable impression.

31 Rosenthal B. Typewritten report submitted by the firm. "Dye Therapy in Chronic Prostatitis." 1931. Work done at the Gouverneur Hospital, New York. Combined Pyridium with other therapeutic measures in treatment of prostatitis and urethritis. Good results obtained. Abstracts of six case histories. Data scanty. Published *Am. J. Clin. Path.* 2:September 1932.

32 Haley F. L. and Goerner A. Typewritten report dated Nov. 25 1930 submitted by the firm in 1931. Careful study of rate and amount of excretion of Pyridium after oral administration. Possibility shown that excreted Pyridium differed from the Pyridium taken by mouth. Experiments showed that urine containing excreted Pyridium was bactericidal and bacteriostatic for *B. coli* and *Staphylococcus aureus* by prolonged contact of twenty four hours or more. Inconclusive data on stimulation of wound healing by Pyridium. These data impressed the referee favorably and still seem to have value in indicating that prolonged contact of bacteria with urine containing excreted Pyridium may kill or hinder the organisms. No reference to publication of this paper has been found.

33 Riaboff P. J. A Study of Pyridium as a Urinary Antiseptic with Special Reference to Its Elimination by the Kidneys. *J. Urol.* 27:329-342 (March) 1932. Report of careful work done under direction of Dr. Thomas and Dr. Kolmer at Pennsylvania. Pyridium had some bactericidal and bacteriostatic action against *Staphylococcus aureus* and *B. coli* in water and urine. But Pyridium excreted in the urine had no bactericidal or bacteriostatic effects on *B. coli* or *Staphylococcus aureus*. Strong acceptable evidence against Pyridium.

34 Gillespie J. B. Experiments on the Antiseptic Properties of Pyridium and Selenium. *Proc. Staff Meet. Mayo Clin.* 7:372-373 (June 22) 1932. No bactericidal action on *B. coli* or *Staphylococcus aureus* by urine containing excreted Pyridium in concentrations of 1:6000 and 1:8000. No bacteriostatic action on *B. coli* and only slight on *Staphylococcus aureus*. Details of the bacteriologic methods used are not given. Presumably the bacteriologic work was satisfactory. This evidence is definitely against Pyridium.

35 Davis Edwin and Sharpe J. C. Urinary Antiseptics. A Comparison of Methenamine, Cycloprol, Pyridium and Acriflavine as to Clinical Efficiency. *J. A. M. A.* 99:2097 (Dec. 17) 1932. Pyridium given by mouth in 0.4 Gm. doses did not cause the secretion of an antiseptic urine. *B. coli* grew luxuriantly in urine containing excreted Pyridium. Occasionally such urine decreased the growth of *Staphylococcus* but usually did not. The authors conclude that Pyridium has practically no effect other than to color the urine. No clinical case reports in this paper.

II Annotated List of Published Articles and Other Reports Consulted in 1933 After the Reply of Merck & Co. to the Report of the Council's Consideration of Pyridium

36 Schofield F. S. Specific Urethritis Treated with an Azo Dye. *Pennsylvania M. J.* 36:15 (Oct.) 1932. This is the publication of the typewritten report reviewed in reference 29. The majority of cases of gonorrhea reported here were complicated. The value of Pyridium therapy was judged by the time interval needed before the patient reached a quiescent stage in which it was deemed advisable to indicate prostatic massage or to search for other foci of infection. This averaged 24.9 days in a group of twenty patients. The referee is not convinced that the improvement noted was attributable to Pyridium. The cessation of injections, massage or the omission of urethral injections in acute gonorrhea established when a drug is given by mouth may be as helpful as the administration of the drug. Dr. Schofield does not report cures attributable to Pyridium but improvement. At best the drug appears from this to be a beneficial adjuvant.

37 Courtiss M. Antiseptics—Pyridium in Kidney and Bladder Infections in Pregnancy. Typewritten copy of a report from the Massachusetts Memorial Hospital in June 1932. Considerable amount of clinical material relating to 137 cases of pyelitis and cystitis. Eighty per cent of patients cured. 94 per cent relieved. Infection recurred in some cases. Lack of observations on untreated cases and lacks consideration of the expected postpartum improvement of infections occurring during pregnancy. Referee not convinced that Pyridium cured 80 per cent of these patients.

38 Goerner A. and Haley F. L. The Penetration of Pyridium into the Tissues of the Genito-Urinary Tract. report from the Long Island College Hospital. Sept. 21 1932. Results showed penetration of the dye into the tissues. No proof that the amount and character of the compound in the tissues has antiseptic and therapeutic effects. Penetration has been previously considered by the Council as stated in this abstract.

39 Marion D. and Magnan L. A. *Union med. du Canada* 61:1061 (Sept.) 1932. Typewritten translation supplied by the firm. Record of results in The Use of Pyridium in Obstetrics and Gynecology. Cases of gonorrhea, pyelitis, cystitis, cervicitis and salpingo-oovaritis. Preliminary work indicating possible value of Pyridium. Referee not convinced by the evidence.

40 Brown T. K. Bacteriological Study of Urinary Infection in Pregnancy and Puerperium with Special Reference to the Use of Pyridium from the Department of Obstetrics and Gynecology, Washington University School of Medicine, St. Louis, 1932. Pyridium found to have some value in combating infections of the kidney due to staphylococci. Pyridium so ineffective in cases of pyelitis and cystitis due to colon bacilli that methenamine was prescribed as a routine along with Pyridium in mixed colon bacillus and staphylococci infections. Symptomatic improvement with Pyridium therapy in colon bacillus infections but the offending organism persisted.

AZOPHENE (MALLOPHENE) NOT ACCEPTABLE FOR N N R

In April, 1932, Azophene (formerly called Mallophene) was presented by the Mallinckrodt Chemical Works, St. Louis, for consideration of the Council as beta-phenyl-azo-alpha-alpha-diamino pyridine hydrochloride. It was proposed for use topically and orally as a genito-urinary antiseptic. Examination by the A. M. A. Chemical Laboratory had shown it to be identical with Pyridium (Collins, G. W. *J. Am. Pharm. A.* 20:445, 1931). Since Pyridium already stood accepted the Council considered accepting Azophene but postponed action until further investigation and disposition of questions which had arisen concerning the former.

Subsequently the Council, as a result of extended investigation, declared Pyridium unacceptable for continued inclusion in New and Nonofficial Remedies because the claims advanced for it as a local, general or urinary antiseptic are unwarranted (See report on Pyridium). In accordance with its original policy of considering Azophene and Pyridium as identical, and since, to the Council's knowledge, there exist no reports indicating that the former is superior in any way to the latter the Council declared Azophene unacceptable for New and Nonofficial Remedies because claims for its usefulness as a local, general or urinary antiseptic are unwarranted.

Committee on Foods

ACCEPTED FOODS

THE FOLLOWING PRODUCTS HAVE BEEN ACCEPTED BY THE COMMITTEE ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION FOLLOWING ANY NECESSARY CORRECTIONS OF THE LABELS AND ADVERTISING TO CONFORM TO THE RULES AND REGULATIONS. THESE PRODUCTS ARE APPROVED FOR ADVERTISING IN THE PUBLICATIONS OF THE AMERICAN MEDICAL ASSOCIATION AND FOR GENERAL PROMULGATION TO THE PUBLIC. THEY WILL BE INCLUDED IN THE BOOK OF ACCEPTED FOODS TO BE PUBLISHED BY THE AMERICAN MEDICAL ASSOCIATION.

RAYMOND HERTWIG, Secretary

TIDAL WAVE CORN MEAL

Manufacturer—Texas Star Flour Mills, Galveston, Texas

Description—Finely granular white corn meal practically free from corn germ and bran.

Manufacture—The manufacture is essentially the same as that given for Ambrosia Cream Corn Meal (*THE JOURNAL*, Oct. 28, 1933, p. 1393) with the exception that all the corn grits stock is reduced and blended together to make the final meal.

Analysis (submitted by manufacturer) —	per cent
Moisture	13.0–14.5
Ash	0.9–1.0
Fat (ether extraction method)	2.2–3.2
Protein ($N \times 6.25$)	7.9–9.4
Crude fiber	1.8–3.0
Carbohydrates other than crude fiber (by difference)	73.9–69.9

Calories—15 per gram, 99 per ounce

IRRADIATED VITAMIN D PASTEURIZED MILK

Distributor—Kennedy Mausfield Dairy Company, Madison, Wis. (subsidiary of The Borden Company, New York)

Description—Bottled pasteurized vitamin D milk irradiated by Steenbock process (patent No. 1,680,818).

Preparation—Milk is irradiated by a CP Carbon Arc Lamp Milk Irradiator equipped with recording meters for measuring lamp energy input, output of milk pump and ultraviolet ray emanations of the arc lamp which provide complete charts

of operation for inspection by plant and health officials. The irradiated milk is pasteurized by standard procedure (holding method, thirty minutes at 63 C), immediately cooled, automatically bottled and capped.

Vitamins—Clinical investigation shows this irradiated milk to be a reliable antirachitic agent protecting practically all infants excepting those prematurely born, contains 50 Steenbock vitamin D units per quart.

Claims of Distributor—Irradiated antirachitic pasteurized milk having otherwise the natural flavor and food values of usual pasteurized milk. Complies with the requirements of the state of Wisconsin and the health department of the city of Madison. The method of irradiation and the equipment are under scientific control.

KRASDALE TOMATO JUICE

Distributor—A. Krasne, New York

Packer—Edgar F. Hurff, Swedesboro, N. J.

Description—Canned pasteurized tomato juice with added salt retains in high degree the natural vitamin content the same as the accepted Hurff Brand Tomato Juice (*THE JOURNAL*, March 18, 1933, p. 818).

VITAMIN D FORTIFIED PASTEURIZED MILK SCOTT-POWELL

Distributor—Scott-Powell Dairies, Philadelphia

Description—Bottled pasteurized grade B milk fortified with vitamin D (vitamin D concentrate prepared from cod liver oil), contains 150 vitamin D Steenbock units per quart.

Preparation—The milk complies with the requirements specified by the laws of the states of Pennsylvania and New Jersey and the cities of Philadelphia and Gloucester and other municipalities in which it is distributed.

See this section for Vitamin D Fortified Pasteurized Milk of W. J. Kennedy Dairy Company, Detroit, for description of fortification with vitamin D (*THE JOURNAL*, July 1, 1933, p. 34). The milk is pasteurized by the standard procedure of holding at 62 C for not less than thirty minutes, is immediately cooled to 3 C and automatically bottled.

Analysis (submitted by manufacturer) —

	per cent
Moisture	87.2
Total solids	12.8
Ash	0.7
Fat	3.9
Protein ($N \times 6.38$)	3.8
Lactose (by difference)	4.7

Calories—0.7 per gram, 20 per ounce

Vitamins—The vitamin D concentrate used in the preparation of this vitamin D milk and the fortified milk are regularly tested biologically. Clinical investigation shows this milk to be a reliable antirachitic agent.

Claims of Manufacturer—A vitamin D fortified antirachitic pasteurized milk having the natural flavor and food values of standard pasteurized milk.

- (1) G. W. C. BRAND AMBER TABLE SYRUP
- (2) IOWA MAID AMBER TABLE SYRUP
- (3) MINNECOPA BRAND AMBER TABLE SYRUP
- (4) VALLEY QUEEN BRAND AMBER TABLE SYRUP

(CORN SYRUPS FLAVORED WITH REFINERS SYRUP)

Distributors—(1) Grocers Wholesale Company, Des Moines, Iowa

(2) Charles Hewitt & Sons Company, Des Moines, Iowa

(3) Bismarck Grocery Company, Bismarck, N. D.

(4) Wilson Mercantile Company, Wausau and Rhineclander, Wis.

Packer—Wheeler-Barnes Company, Minneapolis

Description—Table syrup, corn syrup base (85 per cent) with refiners syrup (15 per cent) the same as the accepted Golden Oak Brand Amber Syrup (*THE JOURNAL*, Dec. 3, 1932, p. 1948).

THE RESPONSIBILITY OF THE PHYSICIAN IN THE PREVENTION, DIAGNOSIS AND TREATMENT OF CANCER

Cancer, it has been said, is an unsolvable problem, certainly for the problem of the cause of cancer not even an approximate solution is available. Indeed, the great central problem of life and cell growth has not yet been solved. Whether these problems are unsolvable, no one knows. The advance of biologic science is marked by efforts to explain the succession of phenomena that are laid bare as investigation proceeds rather than by the complete understanding of basic biologic problems in the final sense. In this gradual progress of science, results of great practical importance are achieved from time to time. The discovery of the tubercle bacillus did not solve the problem of tuberculosis, but it did show the right way for further study and for better control of the disease. How the bacillus produces disease and how the body reacts against the bacillus are still largely unsolved problems. The fact is that science provides no complete, no ultimate explanation of any disease, hence little wonder that the problem of cancer remains unsolved.

Notwithstanding the slowness of scientific progress, the knowledge of cancer is actually growing. The truth is that more advance has been made in detailed knowledge of cancer during the last two or three generations than in all previous time. The details of this new knowledge need not be reviewed item by item. The practical outcome is that, while any complete understanding of cancer has not been reached, the power of medicine to prevent, to diagnose and to treat cancer has been increased enormously. And the responsibilities of the physician with respect to cancer have increased likewise. On him rests primarily the duty to make sure that the individual patient receives the benefit of the knowledge and the measures that tend to prevent cancer. Briefly, prevention of cancer rests mainly on the avoidance and removal of "local irritation." Just how "local irritation" acts to cause cancer is not known but there is no doubt that it may lead to

cancer. Of the tissues liable to such irritations and chronic inflammations may be mentioned the uterine cervix with its lacerations and "chronic cervicitis," the skin and its moles and ulcers, the mouth, the tongue, the mucocutaneous junctions, the breast and the prostate with their chronic hyperplastic inflammations. Here is indeed a wide field for constant preventive efforts by the progressive, cancer-conscious physician.

Self evidently, on the physician rests also the main responsibility for the early diagnosis of cancer, on which in turn depends the outcome of its treatment. In connection with this matter, of such vital significance to the individual patient, the physician must consider thoroughly and conscientiously such questions as these: Has he formulated for himself a wise and practical plan for action in all cases in which the question of cancer may arise? Are his regular patients likely to report to him promptly the appearance of any suggestive symptom or sign? If not, why not? Is he fully prepared to take without delay the necessary steps, either by himself or through competent consultants, to secure the final diagnosis in a given case with a doubtful lesion? Does he realize fully that it may be a fatal error to tell a patient with a suggestive lump or lesion somewhere "to forget it and come back next month"? Are the services of a competent pathologist readily available and will adequate specimens for microscopic diagnosis reach the pathologist promptly and in the proper state of preservation? Are the special experts to whom he may refer cases for diagnosis and treatment fully equipped in all respects for prompt and efficient service? Does he accept in its full meaning the statement that the treatment of cancer, surgical as well as radiologic, should be entrusted only to those who have adequate skill and experience? These are questions that the physician must answer in a practical and trustworthy manner if he is to meet his responsibility with respect to cancer as now understood. Better control of cancer by prevention, early diagnosis and prompt treatment rests with the physician.

DINITROPHENOL AND ACCELERATED TISSUE METABOLISM

The discovery of a drug that gives promise of therapeutic usefulness is always an event of interest in medicine. Careful investigation and cautious clinical trial are indispensable before widespread application is undertaken. There have been few therapeutic innovations that have not sooner or later been found to present some limitations to their unqualified practical usefulness or even to involve unanticipated hazards to health. That is why it is extremely important to learn every ascertainable detail of the pharmacodynamic action of new products as early as possible. The problems of the range between useful and lethal doses, the causes of death, and possible antidotes must be considered with great care. This statement may be applied specifically

to 1-2.4 dinitrophenol, a substance demonstrated only a few months ago to produce fever in experimental animals¹ The observation that this compound can increase the metabolic turnover at once suggested its resemblance to well known stimulants of oxidative metabolism, such as the hormones thyroxine and epinephrine

The questions raised by the study of dinitrophenol, notably at the Stanford University School of Medicine in San Francisco, have already been considered to some extent in *THE JOURNAL*² Investigation of its pharmacologic properties shows that it has the power to increase metabolism to high levels without causing important damage to vital organs and functions Serious harm is apparently caused by the drug only in large doses, which produce too great metabolic stimulation with resulting fever In low, or therapeutic, doses, the metabolism may be increased 50 per cent or more over considerable periods without unpleasant symptoms or toxicity Such an action is useful in treating obesity, since the increased metabolism results in loss of weight, just as it does with thyroid medication As a suitable regimen of dinitrophenol medication for adults there has been suggested, on the basis of the early clinical trials in the reduction of obesity, an initial daily dose of 100 mg of the sodium salt orally, taken with meals, with an increase at weekly intervals until a dose is established that causes a loss of body weight of between two and three pounds weekly or too severe or unpleasant symptoms of warmth and sweating Such a procedure has been reported to be free from demonstrable evidences of cumulative or toxic effects Certain limitations, however, apply to a few susceptible persons

More detailed information as to the precise function of dinitrophenol is now available³ All of the disturbances provoked by the administration of dinitrophenol are attributable to a single primary action, that of accelerating the rate of oxidative metabolism The magnitude of this acceleration may approach values attained physiologically only under conditions of vigorous muscular exercise and far exceed those resulting from administration of the hormones normally concerned with the regulation of metabolism, thyroxine and epinephrine Specifically, the increase in oxygen consumption may amount to more than ten times the resting rate The studies at Stanford University show that the rise in body temperature that follows the increase in oxygen consumption is secondary to the acceleration in metabolism During the action of the

drug, pronounced decreases occur in liver and muscle glycogen, while blood sugar and lactates and muscle lactates tend to rise The total carbohydrate disappearing, however, accounts for less than half of the oxygen consumption The principal fuel of the accelerated metabolism must therefore be other than carbohydrate As there seems to be no increase in urinary nitrogen output, one may assume that fat is lost from the body Such observations fail to reveal any differences between the "excess" metabolism of dinitrophenol and that occurring normally Danger arises when the waste heat cannot be effectively disposed of Dinitrophenol is rapid in action compared to thyroxine, it apparently does not exhibit the complication of sympathetic stimulation so characteristic of epinephrine With fatal doses of the new drug, a decrease in respiration and oxygen consumption occurs shortly before death At this time lactates rise and the carbon dioxide combining power and the pH of the blood fall, indicating the development of a premortal anoxemia and acidosis However, with nonfatal doses, none of these phenomena appear Suitable cautions have already been given in *THE JOURNAL*, they warrant repetition The drug must be sufficiently pure, it has been stated that much of the material on the market is not sufficiently pure Aside from the skin reactions, the chief danger from this drug is in the indiscriminate or careless overdosing that may result from its sale to the public It has already been demonstrated that an overdose of sufficient size will cause a fatal pyrexia in man, just as it does in experimental animals That an overdosage may be toxic does not constitute a sufficient reason for not using dinitrophenol any more than for any one of many potent drugs commonly employed by physicians, but it does indicate that the treatment must be directed by the physician For maximal safety the initial dose of dinitrophenol should be small, and increasing doses may be employed only as the clinical response seems to warrant

"AVAILABLE" IRON IN THERAPY

The question of the type of compound to be preferred for use in therapy with iron has been the subject of debate for many, many years Empirically, the inorganic salts of the element found widespread use long before the end of the last century During that period distinctions began to be made between so-called organic and inorganic combinations of iron The term "masked iron" was sometimes given preference over the expression "organic iron" From the latter point of view the acetate and albuminate of iron for example, were both classified with inorganic iron because they are capable of dissociation and the iron therein is precipitated by ammonium sulphide Many sources of "food iron" that is, iron as it is present in common food materials such as the yolk of egg, appeared to belong to the category of "masked iron" At one period it was widely believed that 'food iron' and related

³ Hall V E, Field J D, Sahyun M, Cutting W C and Tainter M L Carbohydrate Metabolism, Respiration and Circulation in Animals with Altered Metabolism Heightened by Dinitrophenol *Am. J. Physiol.* **100** 432 (Nov.) 1933

compounds of the element possess a pronounced advantage from the point of view of readiness of absorption and assimilation. In the course of time, however, the pendulum swung away from this extreme view, leaving the conviction among most critical students of the subject that inorganic iron follows the same course as the food iron. At any rate, there was abundant experimental evidence that inorganic iron can function for the hematopoietic needs of the body.

The more recent investigations of the control of nutritional anemias produced in animals by the use of exclusive milk diets have given a new impetus to the critical consideration of iron therapy, particularly in hypochromic anemia. The contributory role of copper represents a new phase of the subject, though it does not fundamentally alter the place of iron. In the case of adults, at least, copper seems to be sufficiently ubiquitous, in the traces that may be requisite, to exclude it from serious consideration in the usual therapeutic routine. Of late, ferric ammonium citrate, used in large daily doses amounting usually to as much as from 4 to 8 Gm., has attained widespread vogue for reasons that are by no means obvious. Many of the formerly popular soluble iron salts seem to have become outmoded.

The availability of iron compounds to an anemic animal can be ascertained by a study of the rate of hemoglobin formation (in the presence of sufficient copper) or by the amount of iron stored in the liver. Recent tests of the former type have been made by Elvehjem, Hart and Sherman¹ at the University of Wisconsin. They show that the iron in a variety of soluble, readily dissociated salts is utilized with practically equivalent ease. This applies, for example, to ferric chloride, ferric pyrophosphate, ferric hypophosphite and ferric glutamate. Elvehjem, Hart and Sherman point out that this does not mean that all the available compounds are equally valuable. Other properties, such as taste and toxicity, are important factors. They have found that ferric pyrophosphate possesses many fine qualities. The iron in pyrophosphate not only is available but is held in such firm combination that it does not produce the astringent effects so characteristic of other iron salts. This salt, they add, may also be valuable in cases of anemia with achlorhydria, because it is soluble in neutral solutions and may be more readily assimilated in the absence of hydrochloric acid.

The Wisconsin biochemists have also made a real contribution to the comparative value of ordinary foods as sources of iron. This cannot be based on their total chemically assayed iron content. Each food contains a portion of iron that is readily utilized for hemoglobin formation and a portion that is unavailable and may consist mainly of hematin compounds. This may help to explain why certain iron salts appear to be superior

to food iron in the treatment of responsive anemias. Elvehjem, Hart and Sherman have found that the available iron in foods can be estimated "with a fair degree of accuracy by relatively simple methods, such as Hill's dipyriddy procedure."² On this basis about one half of the total iron of such products as wheat, oats and yeast is "available" iron. The Wisconsin investigators have concluded that various forms of non-hematin iron, even insoluble salts, are much superior to hematin compounds (organic iron) as a source of iron for the body. Hematin compounds, they state, have no place in the group of therapeutic agents used for hypochromic anemias. Further research along these lines serves to dispel a considerable number of current prejudices, claims and misconceptions as well as to promote more rational practices in the domain of iron therapy.

Current Comment

THE CLINICAL PATHOLOGIST AS A TEACHER

The evolution of the clinical laboratory in the modern hospital constitutes one of the remarkable advances of the present century. The hospital laboratory is often the axis about which the scientific work of the institution revolves. In his presidential address before the recent annual meeting of the American Society of Clinical Pathologists, Walter M. Simpson¹ directed particular attention to the role of the clinical pathologist as a teacher. On the clinical pathologist, he pointed out, devolves a large share of the responsibility for the correlation and dissemination of the scientific aspects of hospital medical practice. The teaching activities of the alert clinical pathologist may assume several forms. A cheerful willingness to give a correct interpretation to laboratory results in the light of clinical observations constitutes one of the most fruitful forms of medical teaching, particularly as related to the welfare of the patient. The hospital staff conference and the clinicopathologic conference provide perhaps the best opportunities for the pathologist to contribute a large share to postgraduate medical education. The well directed clinicopathologic conference makes available the university idea of postgraduate medical education in every hospital that has a capable clinical pathologist. It is Simpson's belief that the clinical pathologist who does not fulfil this duty is missing his greatest opportunity to gain the respect and confidence of his medical brothers. Such conferences are capable of providing constant stimuli to the scientific activities of the hospital. Intelligent correlation and interpretation of the information gained by postmortem examinations will quite naturally create interest in morbid anatomy. The clinician is thus provided with a real incentive to obtain permission for postmortem examinations on his patients.

¹ Elvehjem, C. A., Hart, E. B. and Sherman, W. C. The Availability of Iron from Different Sources for Hemoglobin Formation. *J. Biol. Chem.* 103: 61 (Nov.) 1933.

² Hill, R. *Proc. Roy. Soc. London Series B* 107: 205 1930.
¹ Simpson, W. M. The Clinical Pathologist as Consultant and Teacher. *Am. J. Clin. Path.* 3: 327 (Sept.) 1933.

The successful conduct of clinicopathologic conferences requires consummate tact. If the emphasis is placed too heavily on postmortem pathology at the expense of practical clinical aspects, the interest of the average practitioner will not be aroused. Attendance at the clinicopathologic conference should be optional and induced only by the excellence of the program. Such conferences should be held often enough to sustain interest. The weekly or biweekly clinicopathologic conference, lasting for an hour or an hour and a half, but not longer, will accomplish this end. The logical place for the conference is at the hospital. The time for the conference should be chosen with a view to inconveniencing the smallest number of persons. The programs should be arranged so that a wide variety of subjects may be discussed at each conference, in order that physicians in special fields may be induced to attend the conferences regularly. Recurring discussion of commonly encountered diseases is of much greater importance than emphasis on the presentation of rare and unusual ones. The clinical pathologist is the natural and logical director of such conferences. While it is generally admitted that the pathologist is usually "the court of last appeal," the shrewd and tactful pathologist will rarely exercise this prerogative. To give instruction to the informed physician is a different matter from teaching the uninformed layman or medical student. The exercise of restraint will often accomplish much more than a practice of forcing his opinions and decisions on his fellow practitioners.

FEDERAL MEDICAL RELIEF AND EMPLOYEES' COMPENSATION

In these trying times, actions ensue so rapidly in Washington that it is increasingly difficult for a medical journal, published weekly, to keep its readers abreast of the last minute advice regarding their relationship to government activities. Last week THE JOURNAL published an extended statement concerning 4,000,000 workers involved in the Civil Works Administration. It pointed out that apparently these 4,000,000 workers had been placed under the coverage of the Federal Employees' Compensation Act and that therefore they would be entitled to medical care in government hospitals and from government physicians for every injury and occupational disease sustained in the performance of duty. Now comes a revision of the original rules and regulations with a statement that it is retroactive to November 16. Apparently, employees of the Civil Works Administration may have the right to choose their own physicians under such circumstances. The new regulation states specifically that the benefits provided are not intended to be payable as compensation under the United States Employees Compensation Act. A protest by the Indiana State Medical Association directly to the President of the United States and to the United States Employees Compensation Commission accompanied by a similar protest by the director of the Unemployment Relief Commission of that state,

brought a reply indicating that all reputable physicians willing to give treatment at reasonable charges may be used for the care of employees of the Civil Works Administration. Moreover, the director of relief was authorized to notify local administrators at once that they are authorized to advise the local medical profession accordingly and to make arrangements to permit reputable private physicians to participate in rendering this service in places in which government medical officers and hospitals are not available and reasonably accessible. As long as the latter rule is in effect it will operate as a bar to the free choice of physicians by injured employees in such places as can make available government service. In the meantime the American Medical Association has called the situation to the attention of the Federal Civil Works Administrator, urging him to abolish the limitations described and to amend the regulation so as to permit employees to select their own physicians either from all doctors of medicine licensed to practice or else from lists of physicians approved by the United States Employees' Compensation Commission.

Association News

THE CLEVELAND SESSION

Authorization of a Symposium on Amebic Dysentery in the Scientific Exhibit

The Committee on Scientific Exhibit of the Board of Trustees has authorized a symposium on amebic dysentery in the Scientific Exhibit at the Cleveland Session, June 11-15, 1934. The sections of the Scientific Assembly taking part are the Section on Practice of Medicine, the Section on Gastro-Enterology and Proctology, the Section on Pathology and Physiology, the Section on Pharmacology and Therapeutics and the Section on Preventive and Industrial Medicine and Public Health. The symposium will consist of a group of exhibits dealing with the diagnosis, treatment and prevention of amebic dysentery. Application blanks for space may be obtained from the Director, Scientific Exhibit American Medical Association, 535 North Dearborn Street Chicago.

MEDICAL BROADCAST FOR THE WEEK

Talks over Network of the National Broadcasting Company

The American Medical Association broadcasts each Monday afternoon from 4:45 to 5 o'clock Eastern standard time (3:45 central standard time). There will be no talk on Monday, January 1. The next talk over the National Broadcasting Company network will be on January 8.

Radio Talks from Station WBBM

The American Medical Association broadcasts on Tuesday and Thursday mornings from 8:55 to 9 o'clock central standard time over Station WBBM (770 kilocycles or 389.4 meters).

The subjects for the week are as follows:

January 2 Pasteurized Milk
January 4 Health Regulations

There is also a fifteen minute talk sponsored by the Association on Saturday morning from 9:45 to 10 o'clock over Station WBBM.

The subject for the week is as follows:

January 6 Fermentation and Digestion

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES NEW HOSPITALS EDUCATION PUBLIC HEALTH ETC)

ARKANSAS

Society News—Among others, Dr Earle H. Hunt, Clarks-ville, spoke before the Ninth Councilor District Medical Society in Harrison, December 5, on 'Vomiting in Pregnancy'—Dr Benjamin H. Hawkins, Mena, among others, addressed the Sixth Councilor District Medical Society in DeQueen, November 28, on "Lethargic Encephalitis"

Antimalaria Campaign Started—With the appointment of Dr William B. Grayson, Little Rock state health officer as state director of malaria control work, November 29, the statewide campaign in Arkansas was inaugurated. Work was begun at several places, December 4. The state has been divided into five districts. Salaries and wages will be paid by the Civil Works Administration, while expenses for materials and supplies will be borne by the U. S. Public Health Service.

CALIFORNIA

Lectures on the Heart—The Los Angeles County Heart Association conducted a series of lectures on heart disease in Los Angeles, December 7-8, the first three sessions of which were joint meetings with the Los Angeles County Medical Association. Dr Frank R. Nuzum, Santa Barbara, was the guest speaker, on 'The Use of Tissue Extracts in Angina Pectoris and Spastic Arterial Disease'. Local physicians participating in the program were Drs. Edward Richmond Ware, R. Manning Clarke, Phillip E. Rothman, Henry H. Lissner, Donald J. Frick, Burrell O. Raulston, John C. Ruddock, Howard F. West, Robert W. Langley, William H. Leake and Arthur Stanley Granger.

CONNECTICUT

Beaumont Exhibit—A collection of all the editions of the work of Dr. William Beaumont on the physiology of digestion, and other documents and memorabilia having to do with his life are on display at Yale University School of Medicine, in recognition of the centenary of the publication of "Experiments and Observations on the Gastric Juice". Included in this collection are two copies of the first edition, published by Allen in Plattsburgh, 1833, one of them in the original cover, a copy of the first edition published in Boston, 1834, a first edition of Combe's reprint, Edinburgh, 1838, a copy of the second edition, published by Goodrich in Burlington, 1847, a first edition of the German translation, Leipzig, 1834 and two copies of the first edition of the facsimile, reprinted in Boston 1929 on the occasion of the thirteenth International Physiological Congress. There are photostatic copies of Beaumont's license to practice medicine, granted in June, 1812, by the Third Medical Society of the State of Vermont, Beaumont's commission as surgeon of the U. S. Army, signed by President John Quincy Adams in 1828, and an early comment of Beaumont on the case of Alexis St. Martin, on whom his experiments with gastric juice were performed, published in the *Philadelphia Medical Journal* in 1826. The original letter sent by Beaumont in 1834 to Hezekiah Howe, New Haven book dealer, is in the collection. In this letter he says:

Will you please to let me know what number of copies of my Experiments and Observations, etc. you may have remaining on hand unsold soon as convenient? I shall probably have occasion to recall all surplus books from the Eastward to supply the Western market, my depot there having become nearly exhausted and the demand for them continuing.

The exhibit includes a letter from Benjamin Silliman, professor of chemistry at Yale, to Beaumont in 1823, which gives directions for sending a specimen of gastric juice to Prof. Jacob Berzelius in Sweden. There is also a volume of Proceedings of the Connecticut Medical Society in which reference is made to the election of Dr. Beaumont as an honorary member in 1833 and an account is given of his appearance before the society to demonstrate his patient in 1834.

FLORIDA

County Society Organizes Credit Bureau—Members of the Orange County Medical Society recently organized the Orange County Credit and Collection Bureau in Orlando. A state charter has been granted and the incorporators are Drs.

Calvin D. Christ, chairman, Horace A. Day, vice chairman, John R. Chappell, secretary, John S. McEwan, Lawrence C. Ingram, Meredith Mallory and Samuel A. Shoemaker. Credit rating of prospective patients will be made available to members of the society, and the bureau will serve as a clearing house for the physicians' accounts.

ILLINOIS

Society News—Dr Ernest Sachs, St. Louis, spoke before the St. Clair County Medical Society in Belleville, December 6, on 'Diagnosis and Treatment of Brain and Spinal Cord Injuries'—Dr Joseph L. Miller, Chicago, was among the speakers at the meeting of the Tri-County Medical Society (Henry, Knox and Warren), November 16, his subject was treatment of migraine.

Reserve Officers' Reception—The Cook County chapter of the Reserve Officers Association of the United States will give a reception in honor of Major General and Mrs. Preston Brown at the Army and Navy Club, January 6. All reserve officers, whether members of the association or not, are cordially invited and asked to bring, as their guests, ladies and also prospective members of the officers' reserve corps. Further particulars may be obtained from Col. Gilbert Fitz-Patrick, 185 North Wabash Avenue, Chicago, or from the headquarters of the association, 53 West Jackson Boulevard.

State Advisory Board in Public Health—At the first meeting of the state board of public health advisers, December 4, called by the state health commissioner, three committees were appointed to work out details and recommend practicable programs for dealing with heart disease, amebic dysentery and trachoma. It was recommended at this meeting that the state department of health discontinue its treatment of patients with trachoma and restrict its activities in this connection to education in preventive practice. The promotion of prophylaxis against diphtheria and typhoid and the early adoption of a vigorous state-wide program for the control of heart disease were urged.

Chicago

Dr. Doan to Lecture on Leukopenias—Dr Charles A. Doan, professor and head of the department of medical and surgical research, Ohio State University School of Medicine, will present an address before the Chicago Medical Society, January 10, on "Leukopenias from the Standpoint of the General Practitioner." January 14, the society will hold a memorial meeting in honor of its founder, Dr. Nathan S. Davis. The speaker will be Dr. James B. Herrick.

Course in Ophthalmology—Beginning January 1, a course on ophthalmology will be carried on in the hospitals of Chicago for interns and residents in this specialty, it has been announced. Two hundred hours of instruction will be given by fifty-three instructors from the universities and hospitals in the city, the lectures to be divided evenly between the fundamental and the clinical branches. Practically all the lectures will be delivered at the Illinois Eye and Ear Infirmary.

Society News—Speakers before a joint meeting of the Chicago Roentgen Society and Chicago Orthopedic Club, December 14, included Drs. Julius Brams on 'Congenital Absence of the Femur' and Charles N. Pease, 'Injuries to the Intervertebral Disk and Vertebra Following Lumbar Puncture'—Among other speakers Dr. Joseph Greengard spoke on 'Comparative Tuberculin Tests in Children' before the Chicago Tuberculosis Society, December 14—Dr. John Philip Sandblom, Orebro, Sweden, among others, spoke at a meeting of the Chicago Society of Internal Medicine, December 18, on 'Physiology of the Human Gallbladder Studied in Connection with Blood Transfusion and After Stomach Operations'—Speakers before the Chicago Gynecological Society, December 15, were Drs. George T. Palmer, Springfield, on 'Tuberculosis in Its Relation to Pregnancy' and Irving F. Stein, 'Oxygen Pneumoperitoneum in the Diagnosis and Treatment of Tuberculous Salpingitis'.

INDIANA

Society Anniversary—The eighteenth annual meeting of the Indiana Society for Mental Hygiene, December 4, was an observance of the twenty-fifth anniversary of the mental hygiene movement. Among the topics discussed were 'The Mental Hygienist's Attitude Toward Birth Control,' 'Conservation and Prevention,' 'Mental Hygiene and Education' and 'Mental Hygiene and Crime'. Speakers included Drs. Charles P. Emerson, Indianapolis; S. Spafford Ackery, Louisville; Louis A. Lurie, Cincinnati, and Olga Hoffman, Madison.

KENTUCKY

Lectures for Practitioners—The Franklin County Medical Society was host for a course of lectures conducted under the auspices of the Kentucky State Medical Association at Frankfort, November 23. Drs Emmet F Horne and Owsley Grant, both of Louisville, spoke on heart disease and prostatic and kidney diseases, respectively. The lectures were illustrated with motion pictures and slides and each was followed by discussion. A similar course was held in Williamstown for Grant County physicians in October by Drs Virgil E Simpson and Frank P Strickler. Discussions were presented on disease of the thyroid and of the gallbladder.

Society News—A symposium on the thyroid gland was presented before the Jefferson County Medical Society, Louisville, October 2, by Drs Adolph O Pfingst, R Alexander Bate and William O Johnson. At a combined meeting with the Louisville District Dental Society, October 16, speakers were Dr John Stites, on 'Dental Infections as Related to the Field of Medicine' and Orville B Coomer, DDS, "The Growing Interdependence of Medical and Dental Practice."—Dr William R Davidson, Evansville, Ind, among others, addressed the semiannual meeting of the Southwestern Kentucky Medical Association at Marion, October 24, on 'The Infected Hand'.

MARYLAND

Society News—Dr Simon Flexner, New York, addressed the annual meeting of the Baltimore City Medical Society, December 1, on "Polio-myelitis and Other Virus Infections of the Central Nervous System."—At a meeting of the Allegany-Garrett County Medical Society, November 3, Drs Walter T Harrison, Washington, D C, spoke on diphtheria immunization, and Karl Winfield Ney, New York, the idiopathic epilepsies.—Dr Allen W Freeman, Baltimore, spoke before the Howard County Medical Society, recently, on 'The Future of Rural Medical Practice'.

MASSACHUSETTS

Society News—Speakers at the fifth annual meeting of the New England Obstetrical and Gynecological Society, November 22, included Drs Frank A Pemberton, Boston, on "Cancer of the Cervix—Prevention and Treatment", Stewart H Clifford, Boston, "Diseases of New-Born in Early Days of Life," and Herbert B Nelson, Boston, 'Analgesia in Labor'.—Dr Edward D Churchill, Boston, among others spoke before the Norfolk District Medical Society in Roxbury, November 28 on "Surgical Treatment of Empyema".

Personal—Dr M V Govindaswamy, delegated by the Mysore government (India) to make a special study of American psychiatry, is now serving as clinical assistant at the Worcester State Hospital, collaborating in the research activities. For the past two years Dr Govindaswamy has served as clinical assistant at the Bangalore Mental Hospital.—Dr Charles H Lawrence, Jr, has resigned as assistant professor of endocrinology at Boston University Medical School.—Dr Frederick L Bogan, Boston, was appointed superintendent of the Sanatorium Division, Boston City Hospital, November 24, succeeding the late Dr John F O'Brien.

MICHIGAN

Meeting on Medical Economics—A special meeting of the Wayne County Medical Society, December 20, was devoted to medical economics with discussions of the Federal Emergency Relief Administration and the Civil Works Administration as concerns physicians. Michigan poor relief laws and the doctor's situation in relation to them, the abuse of free and part pay clinics and the state hospital at Ann Arbor. Mayor John W Smith suggested that the unemployed be given health examinations by their private physicians so that each man may be in good physical condition when he is called back to work. This plan was also urged for all employees under the Civil Works Administration because an examination at this time would protect the government against malingerers or the future it was stated. Plans to correct certain abuses were registered and a permanent clinics committee appointed to execute them. The society will hold a rally on tuberculosis, January 22. Drs Henry C Swann, Chicago and Bruce C Lockwood will discuss Pathogenesis and Symptomatology of Childhood Tuberculosis. Henry F Vaughan, Dr PH, commissioner of Health of Detroit will speak on Medical Practice.

MINNESOTA

Society News—Speakers before the Hennepin County Medical Society, December 27, were Drs Jennings C Litzenberg and Claude J Ehrenberg, Minneapolis, on endocrine control of menstruation and dysmenorrhea, respectively.—The Minnesota Academy of Medicine was addressed, December 13, by Drs Halbert L Dunn and Martin Nordland on "Practical Experiments in What Actually Constitutes a Good Clinical Record" and "Diagnosis and Treatment of Malignant Tumors of the Thyroid Gland," respectively.—Dr Earl E Carpenter, Superior, was elected president of the Interurban Academy of Medicine, November 15, whose membership is made up of Duluth and Superior, Wis, physicians. Dr Frank J Hirschboeck, Duluth, is the retiring president.

MISSISSIPPI

Program of Malaria Control—A state-wide malaria control and sanitation program will be carried on in Mississippi over a period of two and one-half months, newspapers reported November 30. It will be handled as a federal works project instead of an undertaking of the state Civil Works Administration. Dr Felix J Underwood, state health officer, is supervisor of the program, and Dr George E. Riley, chief of the malaria control division, will direct the malaria projects.

MISSOURI

Personal—Dr John C Morfit was recently elected president of the St Louis Medical Society.—Dr Paul F Stookey has been appointed epidemiologist of the Kansas City Health Department.

Kansas City Academy Programs—The remaining lectures in the series of seven which comprise the 1933-1934 season of the Kansas City Academy of Medicine are as follows:

Dr William T Peyton, director cancer clinic, University of Minnesota, Advancement in Diagnosis and Treatment of Malignant Disease, January 10.

Dr Ralph S Muckenfuss, assistant professor of medicine, Washington University School of Medicine, St. Louis, Practical Clinical and Therapeutic Problems as Related to the Study of Virus Disease.

Dr Charles A Doan, professor of medicine and medical research, Ohio State University College of Medicine, Clinical Implications of Experimental Hematology.

Dr Loyal Davis, professor of surgery, Northwestern University School of Medicine, Chicago, Clinical Application of the Newer Discoveries in the Field of Neurological Surgery.

Other lecturers in the series were Drs Albert M Snell, Rochester, Minn, on "Differential Diagnosis of Conditions Associated with Jaundice", Richard H Jaffe, Chicago, "Endothelial Reticular System: Its Clinical and Pathological Relationships" and Dr Robert T Frank, New York, "Clinical Application of Newer Discoveries in the Field of Endocrinology".

NEBRASKA

Society News—Dr Walter Lawrence Biering, Des Moines, Iowa, President-Elect, American Medical Association, delivered the principal address at the annual banquet of the Omaha-Douglas County Medical Society, December 12, on "Historical Sequence in Medical Events".—Drs Thomas L Houlton and Abram E Bennett, Omaha, addressed the Otoe County Medical Society, Syracuse, December 11, on 'Head Injuries and Their Immediate Treatment' and 'Post-Traumatic Neurological Syndromes, respectively'.—Speakers at the January meeting of the Lancaster County Medical Society, Lincoln, will be Drs Miles J Breuer, on 'The Psychic Factor in the Etiology of Tuberculosis,' and Ruth A Warner and Grace Loveland, 'A Satisfactory Technique for Early Pregnancy Tests'. Dr Newell C Gilbert, Chicago, addressed the society, Lincoln, December 5 on heart disease.

NEW JERSEY

Award to Dr Theobald Smith—The Copley Medal of the Royal Society of London has been awarded to Dr Theobald Smith, director emeritus of the department of animal pathology, Rockefeller Institute for Medical Research, Princeton, in recognition of his research on diseases of man and animals, notably his work in establishment of the theory of insect transmission of diseases.

NEW MEXICO

Typhoid in Taos County—Sixty-two cases of typhoid occurred in twenty-nine families in two Spanish American communities near Taos during the early fall according to the New Mexico Health Officer for November. Several possible sources for the epidemic were unearthed by Dr C H Douthett who made an investigation for the state department of health but none were definitely proved. Both Rinchos de Taos and

Llano are on an irrigation ditch from which many persons take their drinking water. The few wells in the area are dug wells open to surface drainage. Samples of water from the ditch were negative for *B. coli*, but water from four wells was positive. Twenty-five cases were definitely the result of direct contact with other cases in the same house. Others of visits to relatives ill with the disease. Several patients had attended "velorios," gatherings at the homes of persons who have just died. On these occasions friends and neighbors spend the night, eating a midnight supper and breakfast in the home. Because of the distance from the state laboratory at Santa Fe, efforts to identify a carrier through laboratory examination were unsuccessful. Several deaths occurred. Some cases remained to be investigated. About 600 persons in the two communities received complete typhoid inoculations.

NEW YORK

Hospital News—Mr. J. Ward Thompson, superintendent of Rochester Municipal Hospital for thirty years, died, October 27. Contracts amounting to \$882,486 have been awarded for the construction of a state hospital for tuberculosis at Mount Morris. A tumor clinic was opened in November at St. Joseph's Hospital, Elmira, following a suggestion from authorities of the State Institute for Malignant Diseases at Buffalo, as a means of relieving overcrowding at the Buffalo institution. The clinic will be open one hour a week at first.

New York City

Personal—Dr. Joseph Eastman Sheehan has been made a member of the French Surgical Society. Dr. Simon Tannenbaum was the guest of honor at a testimonial dinner at Beth David Hospital, December 17, on his retirement as superintendent of the hospital. He will become medical director of Sydenham Hospital. Dr. William Browning was the guest of honor at a meeting of the Medical Society of the County of Kings, November 21, in recognition of his services in building up the society's library. Drs. James P. Warbasse and Frederick Tilney paid tribute to Dr. Browning who was guest of honor at a dinner at the Montauk Club before the meeting.

Society News—Dr. Howard Lihenthal, among others, addressed the first fall meeting of the International and Spanish Speaking Association of Physicians, Dentists and Pharmacists, November 17, on "Dangers of Cerebral Embolism in Thoracic Procedures." Dr. David Riesman, Philadelphia, delivered the anniversary discourse of the Medical Society of the County of New York, December 18, on "Medieval Universities." Dr. Grant P. Penney, New York, addressed the New York Surgical Society, December 13, on treatment of varicose veins and ulcers. Dr. William Seaman Bainbridge addressed the Society of Medical Jurisprudence, December 11, on "The Role of Trauma in the Production of Cancer." This society celebrated its fiftieth anniversary, December 16.

OHIO

Public Health Lectures—The Academy of Medicine of Cleveland and the Albert Fairchild Holden Foundation of Western Reserve University are sponsoring jointly the fourth annual series of public health lectures. Dr. Howard T. Karsner delivered the first lecture on "The Role of Germs in Modern Life," December 10. The second will be given by Dr. William Evans Bruner, January 14, on "Care of the Eyes in Youth and Age" and the third, February 18, by Dr. Harold N. Cole on "The Skin in Health and Disease."

Appointments at Cincinnati—Dr. Clarence King has been appointed professor and head of the department of ophthalmology at the University of Cincinnati College of Medicine, to succeed Dr. Victor Ray, who has been made professor emeritus. Dr. Gordon F. McKim, professor of urology since 1917, was made professor of surgery and head of the urological division to succeed Dr. E. O. Smith who resigned because of illness. Dr. Smith was also made professor emeritus. To succeed the late Dr. Charles L. Bonifield, Dr. Frank M. Coopock has been appointed professor of surgery in the gynecologic division.

Society News—Dr. George E. Tollansbee, Cleveland chairman, Judicial Council, American Medical Association was the principal speaker at a meeting of the Eighth District Medical Society, in Cambridge, November 1, his subject was "Is Medicine a Profession or a Trade?" Dr. George T. O'Byrne, Lima, addressed the Van Wert County Medical Society, November 7, on "Feeding of Premature Infants with Special Reference to Copper and Iron." Dr. Max M. Zimmerman, Cincinnati, addressed the Stark County Medical Society, Alliance, November 14, on "Surgical Treatment of Acute Abdomi-

nal Emergencies."—Drs. George T. Harding, Jr., and George T. Harding III, Columbus, addressed the Tuscarawas County Medical Society, New Philadelphia, November 9, on "Present Day Conceptions of Mental Disease."—Dr. George I. Nelson, Columbus, addressed the Crawford County Medical Society, Bucyrus, December 4, on cardiovascular disease.

PENNSYLVANIA

Hospital News—The Robert Packer Hospital, Sayre, has obtained a loan and grant of \$425,000 from the Public Works Administration, for use in completion of a seven story brick, fireproof hospital with a two story brick extension. The Hospital Association of Pennsylvania has launched a campaign for exemption of hospitals from the state's new alcohol taxes. St. Joseph's Hospital, Lancaster, recently celebrated its fiftieth anniversary.

Society News—Dr. George W. Grier, Pittsburgh, addressed the Lawrence County Medical Society, December 7, on "Radium Treatment of Malignancy."—Dr. Thomas E. Mendenhall, Johnstown, delivered an address on "Endocrine Secretions" before the Somerset County Medical Society, Somerset, November 21. Among speakers before the Clearfield County Medical Society at the Philipsburg State Hospital, November 23, were Drs. James D. Doyle, Grassflat, on "Control of Complications Arising in Syphilis," George A. Ricketts, Osceola Mills, "Spontaneous Subarachnoid Hemorrhage," and Lester Luxenberg, "Metallic Poisoning."—A symposium on appendicitis was on the program of the Dauphin County Medical Society, Harrisburg, December 5, presented by Drs. Herbert F. Gross, John A. Fritchey, Earle R. Whipple and Frank F. D. Reckord. The Allegheny County Medical Society in cooperation with the Pittsburgh Child Guidance Center sponsored a public lecture in Pittsburgh, December 7, on "Mental Hygiene Problems of Today and Tomorrow," by Dr. Bernard Glueck, New York. The Montour County Medical Society sponsored a symposium on goiter at the Geisinger Memorial Hospital, Danville, December 1. An operative clinic was held in the morning and a scientific program in the afternoon, with Drs. David Marine, New York, Frank H. Lahey, Boston, and William F. Riehoff, Jr., Baltimore. Dr. Harold L. Foss, Danville, was chairman of the program. Dr. Temple S. Fay, Philadelphia, addressed the Cambria County Medical Society, Johnstown, November 9, on "Dehydration and Its Application."—Dr. Walter Estell Lee, Philadelphia, addressed the Delaware County Medical Society in Chester, December 14, on "Postoperative Pneumonia."

Philadelphia

Medical Economics Program—The meeting of the Philadelphia County Medical Society, January 10, will be devoted to discussions of medical economics. Hon. J. Hampton Moore, mayor of Philadelphia, will give an address on "The Municipality and the Medical Profession" and the following physicians will speak: Drs. Frederic C. Elliott, Brooklyn, chairman of the committee on economics of the Medical Society of the State of New York, on "Adjustment of Medicine to the Newer Economic Philosophy," Seth A. Brumm, president-elect Philadelphia County Medical Society, "The Activities of the Commission on Medical Economics in Retrospect," and Francis Ashley Faught, chairman, "Activities of the Commission on Medical Economics in Prospect."

SOUTH CAROLINA

Society News—Dr. Madison Hines Roberts, Atlanta, addressed the Greenville County Medical Society, recently, on problems of the new-born. Dr. William Egleston, Hartsville, president Medical Society of South Carolina, among others, addressed the Fourth District Medical Association at Spartanburg, recently, on functions of the state board of health. The Third District Medical Association held a meeting, October 5, at which speakers included Drs. Ernest W. Carpenter, Greenville, on nasal sinus problems, and George R. Wilkinson, Greenville, on syphilitic aortitis.

TENNESSEE

Hospital News—Drs. Dean Lewis, Baltimore, President, American Medical Association, and James B. McElroy, Memphis, were guest speakers at an institute for physicians at Rutherford Hospital, Murfreesboro, November 27-28, under the auspices of the Commonwealth Fund. Dr. Lewis spoke on tumors of bone, fractures, lesions of the breast and diseases of the thyroid and Dr. McElroy on malaria, anemias and Bright's disease. Wheat's Hospital, Lewisburg, was burned, November 13, with a loss of about \$40,000.

Society News—Dr Daugh W Smith presented a review of 292 cases of incomplete abortion at a meeting of the Nashville Academy of Medicine, December 19. Dr Merrill Moore, Boston, addressed the academy, December 9, on acute syphilitic meningitis—Drs Horace B Cupp and Edward T West addressed the Washington County Medical Society, Johnson City, December 7, on 'The Role of Fluid in Surgery' and 'Surgery of the Biliary Tract' respectively—Dr Martin H Fischer, Cincinnati, addressed the Gibson County Medical Society, Trenton, November 27, on diseases of the blood vessels—Dr Robert B Gaston, Lebanon, was elected president of the Middle Tennessee Medical Association at its semiannual meeting in Murfreesboro, November 23-24. The next session will be held in Springfield. Among the speakers was Dr William D Haggard, Nashville, who discussed appendicitis.

WASHINGTON

Society News—Drs William F Patrick and Ivan M Woolley, Portland, Ore, addressed the Cowlitz County Medical Society, October 11 at Cathlamet on 'Differential Diagnosis and Acute Diseases of Children' and 'X-Ray Diagnosis' respectively—Dr Siegfried I Herrmann addressed the October meeting of the Pierce County Medical Society, Tacoma, October 10, on 'Anomalies of the Gallbladder'—Drs Samuel L Caldwell, Everett, and Elijah C Leach, Arlington, addressed the Snohomish County Medical Society, Everett, October 3, on 'Fractures in the Region of the Elbow Joint' and 'Non-union of Fractures,' respectively—Dr James Marr Bisatillon, Portland, Ore, addressed the Walla Walla Valley Medical Society, October 12 in Walla Walla on 'Differential Diagnosis of Postoperative Lung Complications' and Drs James T Rooks, Jesse W Ingram and Carl J Johannesson, Walla Walla on 'Pulsion Diverticulum of the Pharynx'—Drs David Metheny and Joel W Baker, Seattle, addressed the Yakima County Medical Society, Yakima, October 9 on 'Intra-abdominal Repair of Inguinal Hernia and Retroperitoneal Approach to Subphrenic Abscess,' respectively—Dr James M Bowers, Seattle, presented a clinical study of gastric ulcers at a meeting of the King County Medical Society, Seattle, November 6, the paper was discussed by Dr Andrew B Rivers, Rochester, Minn, who also conducted a clinic at Harborview Hospital in the afternoon preceding the meeting—C Rufus Rorem, Ph.D., Chicago, addressed a special meeting, November 17, on 'Paying for Medical Care' and Drs Arnold W Hackfeld and Donald V Trueblood, Seattle, spoke November 20, on 'Interpretation and Treatment of Functional Symptoms' and 'Radiation Therapy or Surgery for Cancer' respectively—The Lewis County Medical Society gave a banquet in Chehalis, November 13, in honor of its pioneer members—Drs John T Coleman, James M Steicher, Emmogene P Sherman, Chehalis, and William Botzer, Mossrock.

WEST VIRGINIA

Antidiphtheria Campaign—The Kanawha Medical Society and the health department of Charleston conducted an intensive campaign of diphtheria immunization November 9-30. Henry F Vaughan, Dr P H health commissioner of Detroit, visited Charleston November 7 to assist local authorities in planning the campaign which was carried out according to the Detroit plan in which immunization is done in the offices of private physicians. Dr Vaughan also made a formal address on this subject before physicians of the city. Originally planned for only a few days the campaign was continued for the rest of the month. During the first intensive drive 2210 children were immunized in physicians' offices. Toxoid was furnished by the state health department. An unusual number of cases in the city led Dr Hugh B Robins, city health officer, to inaugurate the plan.

WISCONSIN

Hospital Anniversaries—The Marinette and Menominee Hospital, Marinette, celebrated the fiftieth anniversary of its founding November 9 with a reception at which Dr Clarence H Boren reviewed the history of the hospital and the town of Marinette. The hospital staff held an informal meeting in honor of Mr John I Boren, superintendent who has been affiliated with the institution for forty-nine years and of Drs Maurice D Bird, Alexander T Nadeau and Henry F Schroeder who have been associated with the hospital for twenty-five years. The hospital was founded by the late Dr Horace Mann—The Milwaukee Hospital, Milwaukee, celebrated the sevenieth anniversary of its founding November 5. A tablet was unveiled honoring the three chief officers who preceded the present chief, Dr Curtis A Evans.

they were Drs Nicholas Senn, William Mackie and Harry A Sifton. Speakers included Drs Stanley J Seeger, president of the State Medical Society of Wisconsin and Robert Sayle, a member of the hospital staff for twenty-five years. There were also dinners for the nursing staff and for the medical staff, auxiliary board and interns association.

WYOMING

Banquet in Honor of Dr Conway—The Laramie County Medical Society gave a banquet, November 15 in honor of Dr John H Conway, Cheyenne, who retired from active practice in October after forty years service. Dr Galen A Fox, president of the society presided and Dr George P Johnston paid tribute to Dr Conway.

PUERTO RICO

Bust of Dr Ashford—Special ceremonies in the School of Tropical Medicine of the University of Puerto Rico, San Juan, December 16 marked the unveiling of a bronze bust of Dr Bailey K Ashford, recently retired as a colonel of the medical corps, U S Army. Hon Benjamin J Horton, acting governor of Puerto Rico, presented the bust to the school of medicine, and George W Bachman, Ph.D., director, made the speech of acceptance. Other speakers were Carlos Chardon, chancellor of the University of Puerto Rico, and Dr Rafael Bernabe, president Medical Association of Puerto Rico. The casting of the bronze bust was unanimously approved by the legislature to recognize Dr Ashford as founder of the School of Tropical Medicine and as initiator of the first campaign against hookworm disease in America (THE JOURNAL, December 16, p 1976).

GENERAL

Change in Status of Licensure—The New York State Board of Medical Examiners reports the following action taken in September:

License of Dr William J Ryan, Oakfield, N.Y., revoked by the board of regents on the ground that he had been convicted of a felony, namely, criminal abortion.

The state medical board of Ohio reports the following action taken October 3:

License of Dr Johanna A C Roth, Columbus, suspended for six months because of her conviction on a charge of violating the federal narcotic law.

News of Epidemics—The Civilian Conservation Corps camp at Elk Grove, Pa., was placed under quarantine December 7 when four members of the corps developed diphtheria—Schools in ten communities in one section of Muskingum County, Ohio, were closed December 4 to stop the spread of scarlet fever; they were to remain closed until after the holidays—Churches, schools and the public library were closed in Vienna, Ill., December 19, in an effort to prevent spread of scarlet fever—An epidemic of mumps was reported to have affected one eighth of the population of 400 in the village of Pearl City, Ill., December 20. The public school was closed.

CANADA

Society News—Dr Harold Beckwith, Whitehouse, professor of gynecology and obstetrics, University of Birmingham, England, addressed the Toronto Academy of Medicine, October 14 on the menopause. Dr Paul Dudley White, Boston, spoke November 7, on 'The History of the Development of Our Knowledge of Heart Disease.'

New Minister of Public Health—Dr Frank Roy Davis, Bridgewater, was recently elected to the provincial legislature of Nova Scotia as minister of public health, succeeding Dr George H Murphy, Halifax. Dr Davis, a graduate of Dalhousie University, has been medical officer of health of Lunenburg County since 1923 and has been on the surgical staff of Memorial Hospital, Bridgewater, for fifteen years. He also served as mayor of Bridgewater for four years.

University News—Canada's *Lancet and Practitioner* devoted its December issue to the class of 1892 of the University of Toronto Faculty of Medicine. Of fifty-four graduates, six remain in Toronto; fourteen are in Ontario; one is in Manitoba; fourteen live in the United States and twenty have died. One member of the class, Dr Herbert A Prince, is lieutenant governor of Ontario—A medalion of bronze commemorating the late Dr Alexander S Munro, president of the Canadian Medical Association in 1931, was recently unveiled at the University of British Columbia. Dr Munro bequeathed a substantial fund to the university for medical education and a medical school is established at the university.

LONDON

(From Our Regular Correspondent)

Dec 9, 1933

The Radium Treatment of Cancer

The fourth annual report of the National Radium Trust and Radium Commission deals with the work of the past year and also summarizes the progress made in the four years since the commission came into being. There is now a network of seventeen fully equipped radium centers all over the country, and the organization, as originally planned, can be regarded as complete. The commission controls 22 Gm of radium, which is slightly in excess of the amount recommended by the committee of inquiry in 1929 as sufficient for the medical purposes of the country. The present report states that five years must elapse before an answer can be given to the question as to how much value can be attached to the radium treatment of cancer. Hence it is not possible as yet to see what effect the "national" policy is having on the cancer problem. Meanwhile, good work is being done in various directions, despite the discontinuance of the 4 Gm radium "bomb." The commission has been developing a 1 Gm unit treatment at three London hospitals. It is found that this type of massive radiation produces no serious or unforeseen constitutional disturbances with a maximum exposure of six hours a day and is likewise free from danger for the technical and nursing staff. The commission is leaving the problem of the large radium "bomb" to the newly constituted Radium Beam Therapy Research Board. Another valuable part of the commission's scheme is the postgraduate school of radiotherapy at Mount Vernon Hospital and the Radium Institute. More than 300 persons have now received instruction there. During the year a register of statistics to the commission, Mr R. W. Raven, F.R.C.S. has been appointed, and the summary cards supplied by the centers are being used for the compilation of yearly statistics. It is to this department that the greatest interest will be attached, for by its work the value of radium treatment will be determined.

The Toll of the Roads

The death toll of the roads remains a serious problem. In an inquest at Birmingham on a woman aged 68, killed in a street accident, the coroner said that in all these inquiries it was impressed on him that old persons did not stand a chance if they failed. In the main roads carrying fast traffic, people should be given a reasonable oasis of safety for crossing. If necessary traffic must be cut into sections, as was done in continental cities. They had surely got beyond the stage when, because an unfortunate person on foot did something wrong, he must lose his life. There was an onus on drivers in busy thoroughfares to keep a reasonable watch in order to combat some failure on the part of pedestrians. At Preston during the safety week, nineteen persons were injured—twice as many as last year. The chief constable's comment was "It is an unfortunate coincidence, but our efforts were directed to children, not adults. Adult pedestrians are past redemption."

The total number of persons killed in road accidents in Great Britain during 1930 was 7,305, during 1931 it was 6,691, and during 1932, 6,667. During the first six months of 1933 the number was 3,061, as a result of 2,998 accidents. An analysis was made of the fatal accidents according to the hours of the day. During the early morning hours, when there is little traffic on the roads, the percentage is small (0.4). It rises to a small peak between 7 and 9 a. m. (3.4) drops between 9 and 10 (2.6) and then increases, rising to a further peak between

noon and 1 p. m. (7.0). It then declines but rises again after 3 and reaches its highest point between 5 and 6 (9.4). It then gradually decreases but reaches a further peak between 10 and 11 (7.3). These peaks depend on variations in the volume of traffic, both pedestrian and vehicular. Thus there are peaks at the time many people go to work, during the luncheon hours and when a large number return from work. Of the persons killed in the first six months of 1933, 1,581 were pedestrians of whom 857 were killed crossing roads, and of these 224 were passing behind or in front of a stationary vehicle, 314 pedestrians were killed not when crossing the road but when running into the roadway, 46 were killed on footpaths, 71 on a refuge, 84 were killed when walking along roads. Of the pedestrians killed while walking on the carriage way, 66 were walking in the same direction as the traffic and 18 against it. Where no footway is available, the highway code recommends pedestrians to walk on the right of the carriage way, so as to face the oncoming traffic.

THE CAUSES

A long table gives all the causes of the fatal accidents assigned by the chief constables. Only 265 out of 2,963 accidents analyzed gave excessive speed as a contributory cause. Inattention on the part of a driver was given as a contributory cause in 139 accidents. Pedal cyclists gave a high number of cases and in practically all the cyclist was the victim. Of the contributory causes attributable to pedestrians, "running into the roadway" was the most frequent and, next, "pedestrian walking or running from behind a vehicle without due care." In 242 accidents, "pedestrian apparently becoming confused or hesitating in traffic" is given as a contributory cause. Apart from mechanical defects, the most important cause contributed by vehicles was inadequate front lighting (thirty-two accidents). Dazzling headlights contributed to twenty-nine accidents. A frequent contributory cause was obscuration of the views of drivers at corners or bends.

The Congress of Urology

The thirty-third congress of the Association française d'urologie was held at the Faculté de médecine under the chairmanship of Dr. Bernasconi of Algiers. The topic for discussion was "Methods Other Than Prostatectomy for the Treatment of Hypertrophy of the Prostate." The preliminary papers were presented by Drs. Bernard Frey and Raymond Dosset of Paris. Medical treatment by the injection of pepsin-procaine into the prostate, the administration of testicular hormones, and the subcutaneous injection of the male hormone are methods that are being tried out. The resection of the vasa deferentia has been abandoned in France. Roentgenotherapy and radium therapy are of questionable value and they are dangerous in case of infection. Since they are always combined with the use of sounds and with lavage it is difficult to determine just what their influence has been. They are permissible in beginning cases without retention, and in the congestive types, but are contraindicated in aged and infected patients and in those who have large adenomas. There remain the resection methods performed, with the aid of endoscopy by the transvesical or the urethral route. The authors considered these methods comparing them with the results of classic prostatectomy. Partial transvesical resections have advocates in France (Legueu, Heitz-Boyer, Martin-Laval) in cases in which the ordinary operation would be dangerous on account of the size of the tumor, the risk of hemorrhage or the general condition of the patient. Resections by the intra-urethral route and electrocoagulation give in general good immediate results.

This is, however, a delicate operation for the surgeon who has had wide experience with its technic, and it is contraindicated in cases presenting very large or bleeding prostates in which neoplastic degeneration is suspected. The statistics of American surgeons are impressive.

A long discussion arose between the members of the congress concerning their results. Professor Marion prefers prostatectomy in all cases in which the condition of the patient justifies the operation and also in cases in which other methods have proved ineffective. In patients unable to withstand prostatectomy, and in patients strong enough to endure the operation but who have only small adenomas, one can attempt destruction of these by conservative means. The same methods may be tried to destroy larger adenomas in persons who cannot withstand transvesical prostatectomy. Radium should be reserved for weak patients who could not endure an operation. Dr Luys defended his forage operation on the prostate and presented statistics to prove its benign nature. But the endoscopic methods encountered opponents, who contended that they were incomplete and did not always prevent infection, hemorrhage or even death. Blanc of Bordeaux, Guisy of Athens, Gayet and Phelip (Lyons) and Chauvin of Marseilles reported a few successful outcomes in very simple cases, but they expressed the opinion that prostatectomy is still the only effective operation with which to combat adenoma of the prostate, especially since advances in technic have reduced the risk of operation. That is the view also of such eminent urologists of Paris as Papin and Pasteau. In fact, Pasteau rejects every other intervention as illusory and dangerous. Many of the advocates of the various substitutes for prostatectomy, with the exception of Luys, resort to endoscopic methods only in special cases.

Numerous further communications dealing with diverse subjects were presented. Phelip of Lyons cited several cases of urinary infection of dental origin, transmitted by the blood stream. Pasteau reported a case of pharyngeal origin. Widholz of Bern stated that he had secured excellent results in nontuberculous aseptic pyuria by means of intravenous injections of neoarsphenamine in doses of 0.0015 Gm. Mr Pillet reported some curious observations on the effect that, in alkaline urine, the formation of phosphatic, ammoniomagnesian calculi is facilitated by pyrexia, a rise of from 1 to 3 degrees in temperature being sufficient to precipitate these crystals when all the elements are combined. Mr Barbellion called attention to the following test to discover whether a patient has recovered from gonorrhea. After the imbibing of an abundance of beer, massage of the prostate, not followed by lavage or urination within five hours, examination of the urethral secretion for the presence of gonococci. In positive cases, especially if the patient has engaged in coitus, the urine will be found to contain gonococci. In negative cases gonococci will not be found.

Jules Janet and Debrins discussed gonococcal autovaccines and expressed a preference for those in which the gonococcus has been killed at the lowest temperature possible in order not to change its biologic properties. They are superior to stock vaccines because they contain gonococci of the desired strain, and fresh specimens. Jeanbrau and Truc (Montpellier) reported a case of complete retention of urine in a woman for thirteen months which was immediately cured by the Cotte operation consisting in resection of the presacral nerve. Dr Lowrey of New York gave an exposition of three of his procedures in renal surgery. He sutures the wounds of the kidney in nephrectomy with a ribbon of catgut which envelops the organ and which is held in place by passing it cut into several strips into the fibrous capsule. He arrests hemorrhage of the parenchyma by introducing fatty tissue into the wound which he regards as the best type of hemostatic. He performs

nephropexy by fastening the kidney by two strips of chromic catgut, one at each of its poles, the one being attached to the twelfth rib and the other to the quadratus lumborum muscle.

Dr Harvey Cushing Honored

The ceremonies in connection with the formal reopening of the University of Paris, this year, were attended by the president of the republic. The several scientists who were accorded the title of doctor honoris causa were all present, each wearing the garb of his own university. Dr Cesar Vivante, professor of law at the University of Rome, Professor Levi-Civita of the faculty of sciences, University of Rome, Mr Puig y Cadafach, president of the Catalan Institute of Barcelona, Professor Van Itallie of the University of Leyden, Prof Franz Volhard of the University of Frankfurt, and Dr Harvey Cushing of Yale University, on whom special honors were bestowed. Professor Roussy, dean of the Faculte de medecine, made this declaration: "I render public homage not only to one of the greatest surgeons of the United States of America but also to the man whose work in anatomy, physiology and clinical surgery has brought great progress to modern neurology and to the ingenious inventor whose new forms of technic have made it possible, during the past thirty years or more, to save thousands of lives." Then, after enumerating the chief works of this master of neurology and rendering homage to the surgeon and teacher, Professor Roussy concluded with these words: "Georges Clemenceau, then minister of war and president of the cabinet, in recognition of your valuable aid given to the ambulance companies, during the war, in the region of Neufchateau, desired, at the time of your departure from France, to give a testimonial of his esteem and gratitude. His gift was his doctor's thesis in medicine, submitted in 1865, which is a very rare booklet. This esteem, this gratitude, and this admiration, the University of Paris and the medical profession of France are happy to take this occasion to endorse."

Anemia Due to Goat's Milk

Professor Rominger, director of the university children's clinic in Kiel, has begun a research on the pathogenesis and therapy of anemia due to the use of goat's milk. On the basis of comprehensive studies on metabolism in healthy and sick children who were nourished with goat's milk and observations in animal experiments, he discussed the question as to whether anemia due to goat's milk is the result of a trophotoxic or a trophogenic injury. Clinical observations show that it is at least improbable that goat's milk as such has any toxic qualities. Feeding experiments on young growing white rats led to the conclusion that an exclusive diet of cow's milk produces an anemia of the chlorosis type (hypochromic anemia), which is evidently due to a lack of iron, since it can be both prevented and cured by the administration of iron. An exclusive diet of goat's milk produces in very young white rats an anemia of the pernicious type (hyperchromic anemia). This experimental hyperchromic goat milk anemia cannot be cured solely by the administration of iron nor is it due to a lack of vitamin C. Furthermore it can neither be produced nor exacerbated by the administration of unsaturated volatile fatty acids of goat's milk. It can however, be prevented and cured by the injection of liver extracts. It is a complex deficiency disease in which the factor that counteracts any tendency to perniciousness—namely, the so-called extrinsic factor—is absent and hinders iron. The good effects of a combined liver extract and iron therapy were observed by Rominger. Within four weeks therapeutic results could be secured such as were obtained with the former therapy even along with the application of

blood transfusions, usually only after several months. According to these observations arsenic, artificial heliotherapy and extirpation of the spleen are no longer indicated. From the standpoint of prophylaxis, the use of goat's milk without the addition of liver and iron must be avoided but if these additions are made, there is no objection to goat's milk in the diet of infants. It may be mentioned that goat's milk contains more copper than other kinds of milk.

Adopt Policy of Free Choice of Physician

Previous letters have dealt with the reorganization of the federal *krankenassen* system (*THE JOURNAL*, November 18 p 1652). At last the controversy that existed in Berlin between the municipal administration and the *Gross-Berliner Aerztebund*, with reference to the proper care to be given to the so called welfare and unemployed has been settled. To this class belong those who since they have no income pay no dues to the *krankenassen*. The municipality itself must provide for them. Until recently members of this group in some districts of the city had to apply in case of illness to a certain 'welfare physician,' who devoted only part time to this service. This arrangement did not result in very confidential relations between physician and patient. Furthermore the number of part time 'welfare physicians' was so small that often unpleasant situations occurred owing to the crowded conditions prevailing during consultation hours. In other districts, those in need of aid had a free choice of physician, but the compensation of the physicians was very small. Both parties therefore failed to be satisfied with this system, and the medical profession of Berlin carried on a campaign for years to secure for such patients and for themselves something more satisfactory. Now the system of part time physicians has been abolished in Berlin. The physicians now receive a fixed amount annually for each patient who, over an extended period of time belongs to this group, while intermittent care given certain patients is paid for according to service rendered. As a result of a new system in which the *vertrauensärzte*, or confidential physicians, of the *krankenassen*, play an important part there seems to be some expectation that the superfluous use of medicines will be checked. For this purpose a central prescription control center has been established at the municipal bureau of health. Domiciliary treatment will be restored to its former position, to which it is entitled. Thus the old demand of the physicians for a free choice of physician by patients has been set up in Berlin at least as far as the physicians admitted to panel practice are concerned. In view of the financial condition of Berlin it is impossible to satisfy all the financial desires of the physicians.

In Hamburg, the waiting room problem has been taken up by the Hamburg "chamber of physicians," which has declared that it is absolutely inconsistent with the idea of popular sovereignty to make in a physician's waiting room any distinction with respect to patients as to whether they are 'welfare patients' *krankenasse* patients or private patients. Hence, dating from this announcement, special consultation hours for private patients, and the equipment of special waiting rooms for such patients, are prohibited.

The Berlin Academy for Graduate Training

Although for decades facilities for the training of domestic and foreign physicians have existed in the city Berlin will open in January an academy for graduate medical training. The instructors, who must be teachers in the various specialties will be selected by the mayor with the aid of a scientific committee on instructors. The purpose will be to organize graduate medical training on a uniform basis and to afford an opportunity to general practitioners, specialists, assistant physicians in the municipal hospitals and physicians in other communal welfare departments to participate in courses and in

practical activities. It is the plan to organize, for the benefit of physicians of Berlin and vicinity who have little leisure in the evenings, lectures and demonstrations covering one or two hours a week, for a period of from two to three months, in many different hospitals of Berlin. In addition there will be eight to fourteen day courses on selected subjects with practical demonstrations. To give physicians the opportunity to do practical work from clinical points of view, whole day clinical instruction courses with the chief emphasis on practice work will be held in the municipal hospitals, which, it is thought will make for a better understanding between the general practitioner and the specialist.

Further Details on the Higher Institutions of Learning

Reorganization of the higher institutions of learning (*THE JOURNAL* Dec 16, 1933, p 1980) is proceeding in various directions.

The league of the German institutions of higher learning the conference of German rectors, the federation of German university teachers the Bavarian league of university teachers, and the society 'The German State' have voluntarily combined, with a view to promoting a federal organization of all German institutions of higher learning and of the teaching personnel of such institutions. The new organization, under the supervision of the federal ministry of the interior will protect the cultural importance of the German institutions, also in relation to foreign countries and will cooperate in renovating the German system of higher instruction in agreement with the national-socialist world-view and in the endeavor to make the universities an organic part of the German body politic and the national life. Prof. Herwart Fischer, ordinarius in legal medicine at the University of Würzburg, has been chosen as leader of the new organization.

After the beginning of the winter semester the training school which has assumed the task of giving the new type of students preliminary training in statecraft will reopen. The objective of this political training is the acquisition of knowledge that will fit the student to play a prominent part in national politics. The University of Berlin student body has published a work schedule and study plan that illustrate the essentials of this new movement the *fachschaftsarbeit*. According to this plan this work is compulsory for all students of the second and third years. A special training of a wider scope has been prepared for the first year students. Those who have attended German universities three years are not required to participate in the *fachschaftsarbeit* but it is recommended that they do so. The work is not compulsory for women but they will be admitted to the courses as volunteers.

Depending on whatever is their major subject the students are divided into six different groups or so called *fachschaften*. The group interested in popular education will study conditions in eastern Germany, the minority problems of the last century, and German-Russian relations. The group interested in German law will study The State and the protection of races and of nationality in the penal code. In the group interested in political economy, the colonial director of Greater Berlin, of the national-socialist party will speak on national-socialism and colonies. The theological group will discuss symbolics, or historical theology and its significance for our day—particularly Luther Melancthon and Calvin. The medical group will study race problems and social problems. The group interested in the natural sciences will be divided into four subgroups: biologic, geographic, mathematicophysical and chemical. At the close of the semester, every student receives a certificate setting forth the work performed. The movement will have a special journal called *Wissen und Dienst* to be edited by the director of the Berlin circle of the German student federation.

Number of Health Insurance Societies in Germany

From the reports of the head insurance bureaus, it will be seen that at the close of the year 1932 there was a total of 6638 *krankenkassen*, namely, 2,046 communal *krankenkassen* (*ortskrankenkassen*), 428 rural *krankenkassen*, 3,266 *krankenkassen* of industrial units (*betriebskrankenkassen*), and 798 *krankenkassen* of guilds (*innungskrankenkassen*). The last two categories show a reduction in membership, which has been further accentuated since the reorganization of the whole federal health insurance system.

Professor Magnus to Direct Surgical Clinic

The university surgical clinic in the Ziegelstrasse in Berlin (not the clinic in the Charité Hospital, which is under the direction of Professor Sauerbruch) had been closed (by the former government). The new government announced, several months ago, that this famous clinic (Professor Bier being the last incumbent) would be reopened. To this important post Prof. Richard Magnus, chief physician of the Bergmannsheil Hospital in Bochum, has been called. Magnus, who is 50 years old, is a pupil of Friedrich König and Guleke. The hospital of which he has been a director is regarded as the largest hospital in Europe for patients who have suffered accidental injuries. Magnus's numerous publications deal chiefly with the treatment of fractures, war surgery and problems concerning joint infection.

Professor Siebeck Summoned to University of Berlin

The chair of internal medicine and the directorship of the first University Medical Clinic formerly held by Professor His, had been vacant some time, but now Prof. Richard Siebeck, clinician of the University of Heidelberg, has been summoned to occupy the post. Volhard of Frankfurt-on-Main recently rejected the offer, and, still earlier, Schittenhelm of Kiel was not inclined to move to Berlin. Siebeck is 50 years old. At the University of Heidelberg, he has been occupying the chair of his former teacher Krehl. His published writings deal chiefly with disturbances of the circulatory and respiratory organs, and with the kidneys and with the water balance.

JAPAN

Oct 28 1933

Vaccination Against Typhoid

Typhoid vaccination has again become the subject of heated discussion in medical circles all over the country. Typhoid vaccination has been widely adopted in places exposed to this disease and yet its absolute potency is never relied on. At a meeting of the Kitasato Research Institute Dr. Kobayashi of the Keio Medical College recently criticized the value of typhoid vaccination. His paper provoked discussion in various circles throughout the country. His criticism was directed chiefly against the statistical reports of the metropolitan police board. He said that it is very difficult to form a conclusion on the potency of vaccination merely on the basis of statistical research for in a sudden outbreak of typhoid complete protection could not be expected.

Dr. Inokuchi, chief of the prevention bureau of the metropolitan police board, says that in the metropolis in the past eight years about 1,600,000 people have been inoculated almost every year. The percentage that contracted the disease among the inoculated has varied from 3.5 in 1925 gradually down to 0.7 in 1930. On the other hand the death rate among the inoculated averaged 15 per cent more or less but among the noninoculated was about 20 per cent every year. He insists that the smaller death rate must be attributed to the increase in the annual inoculation which tends greatly to reinforce the potency of the vaccination. He says that at least some people

have been inclined to lessen the amount of vaccine used for fear of reactions, but even a smaller quantity and a less potent vaccine, if repeated every year, is a certain preventive. Where sanitation is so poor as in the capital, this inoculation should be considered an essential measure for the time being. Dr. Kajitsuka, dean of the military medical school, says that the army believes in vaccination, even if not in its absolute value, and if an improvement in the kinds of vaccine to be inoculated could be attained, a much greater effect might be realized. Statistically, the death rate in the army has been lowered through yearly inoculation. On the other hand, according to reports given by Dr. Kawaguchi, chief of the isolation hospital of Tokyo, hardly any difference could be recognized between the vaccinated typhoid patients and the non-vaccinated, at least in his hospital. Toxic conditions and nervous system complications seemed rather more severe among the inoculated, among whom the death rate was often higher. Of course, sometimes an inoculated person had a mild attack of typhoid. He therefore was bewildered as to the effect of the inoculation. Some discharged soldiers who had been inoculated while in the army, he says, contracted severe typhoid soon after their discharge. He doubts its essential effect.

Dr. Urabe, medical expert of Nagasaki, a seaport, reported in detail his investigations, saying that since 1926 the number of those who were inoculated had increased every year but that the number of cases of typhoid had increased or remained the same yearly.

In 1931 a sudden outbreak of typhoid took place there, and the rate was quite high. He concludes that the period of immunity is uncertain. He reported 146 cases occurring within one month after vaccination, sixty-six cases within two months, and forty-one cases within three months. Inoculation during an epidemic therefore seems to be of comparatively little use. He adds that a little vaccine should be given frequently rather than a great deal at one time. About 10 per cent of those vaccinated were obliged to go to bed on account of reactions. This was caused by negligence in the observation of the specific type of constitution of some people and also by giving them too much vaccine. He continued that the great loss of money and of time both by the public and by the municipal office should be considered in view of the comparatively small value of vaccination. He earnestly longs for some better measure in typhoid prevention.

Dr. Tashiro, surgeon commander of the imperial navy, in opposition to the former opinion said that he has every reason to believe that the period in which inoculation remains potent is about six months. In the navy every sailor is vaccinated twice a year. The reason typhoid may be contracted in the first month after vaccination he attributes to the fact that the immunizing bodies develop insufficiently during that period to be really potent. In Moji another seaport the typhoid cases were about five a month before general inoculation began all over the city but in April of this year inoculation was given to about 40,000 persons (40 per cent of the whole population) and 4,948 persons were given vaccine orally. In May thirteen cases and in June twenty cases suddenly broke out among those who took the vaccine orally, not among those inoculated.

On the contrary in the city of Ito near Tokyo vaccination against typhoid has been regularly done since 1921, accompanied by improved sanitation necessary to annihilate typhoid. In 1921 139 cases were reported before inoculation but the number of cases has gradually and regularly decreased year by year. In 1932 only three cases were found. The city authorities and the physicians concerned are firm believers in the effectiveness of vaccination. On the whole more statistical investigations must be reported to decide the question. Many believe that the absolute value of inoculation will be established sooner or later.

Free Medical Advice to Athletes

In the physical development research institute of Japan, attached to the educational department, an athletic medical consultation office has been opened. Any one who needs advice on physical training may have a medical examination free of charge. Sports and competitive games are prone to lead young people into some danger of overexertion. The office is in charge of Drs Saito and Shiraishi, the former being the chief of its internal medicine bureau, the latter of the surgical section. From the first day it was open, many athletes and players, both amateur and professional, visited the office to be examined, for this sort of medical advice has long been desired.

Personals

Dr K Futaki has retired from Tokyo Imperial University, where he held the chair of epidemic diseases.

Dr R Arima, an authority on tuberculosis, was decorated by the Hungarian government especially for the donation of his tuberculosis vaccine AO, which he presented while he was staying in Hungary last year.

Chian Sagara (1830-1909) was the first president of the Tokyo Imperial University and the director of its medical department. He adopted German medicine in this country for the first time. The present site of the Tokyo Imperial University was chosen by him. But he fell a victim to slanderous tongues and was obliged to retire from his high position. His after-life was miserable and he was forgotten. On the proposal of prominent people, including the war minister, Marquis Okuma and Viscount Dr Ishiguro, a monument will be erected to this benefactor of Japanese medicine.

Marriages

BYRON LUDWIG STEGER to Miss Delene Elizabeth Lobdell, both of Huntington, Ind., at Wabash, November 15.

THOMAS H TOMLINSON, Thomasville, N C, to Miss Mary Sweeney of Baltimore, at Greensboro, November 16.

KUTCHER THREEFOOT KLEIN to Mrs Iva W Lovell, both of Meridian, Miss., at Jackson, in November.

CHARLES NEIL MCBRYDE, Ames, Iowa, to Mrs Virginia Abbey Swergard at Nashua, September 2.

JOHN M RENEHAN to Miss Helen O'Donnell, both of Ansonia, Conn., at Milford, November 6.

HAROLD D WALTZ, Denver, to Miss Eleanor Frances Bassett of New Orleans, November 29.

THOMAS ROBERT PLUMER, Trivoli, Ill., to Miss Helen Cornelius of Peoria, November 15.

WILLIAM WINSLOW WIEDEMANN JR to Miss Sue Amstutz, both of Toledo, Ohio, October 10.

IRVIN WILLIAM WILKENS, Indianapolis, to Miss Delta Newton of Clifford, September 16.

CLIFTON ROSS TITUS to Miss Mildred Carolyn Mitchell, both of Bassett, Va., October 7.

FREDERICK S WOLF, Baltimore, to Miss Betty Saunders Stern of New York, October 4.

FRANCIS J ROBBER, Willow Grove, Ohio, to Miss Elizabeth McGary of St. Louis, recently.

ROYAL V SHERMAN, Minneapolis, to Miss Elizabeth Alberts of St. Paul, November 18.

JAMES J MORROW, Austin, Minn, to Miss Ruth A Sargent of Red Wing, recently.

JOSEPH WEBB, Springfield, Ohio, to Miss Florence Barlow of Urbana, recently.

JACOB D PINSON to Miss Leah Freeman, both of Philadelphia, August 3.

HUGH WELLMEIER to Miss Helen H Frazier, both of Piqua, Ohio, October 11.

BURT HUBBARD to Miss Stella Carr, both of Lima, Ohio, recently.

MILTON PLOTZ to Miss Helen Ratnoff, both of Brooklyn, recently.

Deaths

Leon Dennis Pierce Clark of New York, University of the City of New York Medical Department, 1892, member of the Connecticut State Medical Society, the American Neurological Association, American Psychoanalytic Association, American Psychiatric Association and the Association for Research in Nervous and Mental Diseases, member and past president of the National Association for the Study of Epilepsy, American Psychopathological Association, New York Neurological Society and the New York Psychiatric Society, for many years on the staffs of the Manhattan State Hospital, Craig Colony for Epileptics and the New York City Children's Hospital, trustee to the Letchworth Village for Mental Defectives, Thiells, N Y, author of "Clinical Studies in Epilepsy," "Psychohistorical Studies of Notable Historic Characters" and of numerous monographs on nervous and mental diseases, and co-author of "Diagnosis of Organic Nervous Diseases" and "Neurological and Mental Diagnosis", editor of *Archives of Psychopathology*, 1926-1927, aged 63, died, December 4, of heart disease.

Frederick Adam Cleland, Toronto, Ont., Canada, University of Toronto Faculty of Medicine 1901, assistant professor of obstetrics and gynecology at his alma mater, member of the American Association of Obstetricians, Gynecologists and Abdominal Surgeons, fellow of the American College of Surgeons, served as senior surgeon with the Canadian Expeditionary Force in Siberia on the staffs of the Toronto General Hospital, St. John's Hospital, Grace Hospital and the Women's College Hospital, aged 59, died suddenly, November 26, of heart disease.

William Le Moyne Wills, San Marino, Calif., University of Pennsylvania School of Medicine, Philadelphia, 1882, member of the California Medical Association, fellow of the American College of Surgeons, formerly professor of clinical surgery, University of Southern California College of Medicine, Los Angeles, at one time member and vice president of the state board of health for many years on the staff of the Children's Hospital, Los Angeles, aged 80, died, December 3.

David Thomas Bowden, Jr., Leonardtown, Md., Johns Hopkins University School of Medicine, Baltimore 1918, at one time assistant professor of epidemiology and public health, University of Oklahoma School of Medicine, Oklahoma City, served during the World War, formerly assistant state health officer in Oklahoma, health officer of Phelps County, Missouri, and St. Mary's County, Maryland, aged 41, was found dead, November 2, of heart disease.

Andrew Jackson Giesy, Portland, Ore., Jefferson Medical College of Philadelphia, 1882, member of the Oregon State Medical Society, emeritus professor of clinical gynecology, University of Oregon Medical School, at one time member of the city board of health, formerly on the staff of the Good Samaritan Hospital, aged 80, died, November 9, of heart disease.

Richard Frothingham, New York, Harvard University Medical School, Boston, 1892, member of the Medical Society of the State of New York and the American Laryngological Association, formerly assistant professor of otolaryngology, Columbia University College of Physicians and Surgeons, aged 67, died, December 5, of heart disease and pneumonia.

Karl Forbes Snyder of Freeport, Ill., Northwestern University Medical School, Chicago 1902, fellow of the American College of Surgeons, on the staffs of the Evangelical Deaconess, St. Francis and Freeport Methodist hospitals, aged 57, died, November 28, of a self-inflicted bullet wound.

Hartland Cyrus Johnson, St. Paul, College of Physicians and Surgeons of Chicago 1885, an Affiliate Fellow of the American Medical Association, aged 73, on the staff of St. Luke's Hospital where he died, November 26, of coronary thrombosis and hypertension.

David Autrey, Marietta, Okla., Memphis (Tenn.) Hospital Medical College 1900, member of the Oklahoma State Medical Association, past president of the Carter County Medical Society, formerly county health officer, aged 66, died, November 21, of heart disease.

Francis Regis Harrison, East Liverpool, Ohio, University of Pennsylvania School of Medicine, Philadelphia 1900, member of the Ohio State Medical Association, on the staff of the East Liverpool City Hospital, aged 54, died, December 3, of heart disease.

Ola Putman & Marceline, Mo., Rush Medical College, Chicago, 1901, formerly secretary of the Linn County Medical Society, aged 55, proprietor of the B B Putman Memorial Hospital, where he died, December 4, of coronary thrombosis

Lamartine O Dudgeon, Sweetwater, Texas, University of Texas School of Medicine, Galveston, 1903, member of the State Medical Association of Texas, on the staff of the Sweetwater Clinic Hospital, aged 57, died, October 1

Henry Langholz, Oak Harbor, Ohio Northwestern Ohio Medical College Toledo, 1888, member of the Ohio State Medical Association, aged 74, died, December 8, in the Pool Hospital, Port Clinton of heart disease

Alpheus Hartley Wood, Emporia, Va Medical College of Virginia, Richmond, 1927, member of the Medical Society of Virginia, aged 35, died, September 28 of acute nephritis and pulmonary tuberculosis

Charles Elmer Park, Yuanjiang, Yunnan, China, Chicago College of Medicine and Surgery, 1913, an Associate Fellow of the American Medical Association, medical missionary, aged 52, died, August 17

Bureau of Investigation

AGAIN THE QUESTIONNAIRE NUISANCE

Franklin M Goodchild, M D, Turns His Attention from Soaps and Cooking Fats to Motor Cars

Time and again this department of THE JOURNAL has called attention to the plague of questionnaires with which the medical profession is afflicted. Let it be admitted that some responsibility for this condition rests on our profession, because so many of us, with easy-going tolerance, fill out such questionnaires instead of putting them in the ash-can where they belong. Most of these inquiries come from advertising agencies or their satellites. Their object is to get, at the expense of a postage stamp, an "expert opinion" that can be twisted in some way to sustain the "health angle" that the advertising agency wants to use in crying the wares of its clients. Occasionally the questionnaires come frankly from the advertising agencies themselves. These, at least, have the virtue of being above-board, even though the impertinence is not diminished. Many of them, however, are sent out under some high-flown name such as "Modern Research Society," "Medical Research Bureau," "National Research Bureau," or some similar appellation. Occasionally they come out under the name of an individual physician.

The latest questionnaire that has been sent to physicians in the past week comes from Dr Franklin M Goodchild, whose stationery carries the address Room 1516, 1250 Sixth Avenue, New York City. Dr Goodchild, according to the records of the American Medical Association was born in Philadelphia in 1891, holds a diploma from Columbia University College of Physicians and Surgeons, 1918, and a New York license of the same date. He is not a member of his local medical society or, of course, of the American Medical Association.

The files of the Bureau of Investigation disclose that more than three years ago—in March, 1930—Dr Goodchild was sending out a questionnaire on the stationery of one Percival White, which described Mr White as a "Research Counsellor" and Dr Goodchild as belonging to Mr White's "Medical Department." Incidentally, the Bureau of Investigation developed the fact that Percival White was one of the owners of an advertising agency known as White and Parton, Inc.

Percival White, through Dr F M Goodchild, was, it seems, interested in having physicians answer five questions relative to the alleged advantages "of the two distinct classes of soap—white soap and colored soap." This calls to mind a similar questionnaire sent out in January, 1929, by the editors of the *Medical Review of Reviews* who wanted to know of physicians whether they recommended white or colored soap, and those that are perfumed or those that are free from odor. This particular questionnaire was referred to in an article on the subject appearing in this department of THE JOURNAL, March 23, 1929.

Dr Goodchild in his letter of March 4, 1930, stated that it was his intention to make public "through the daily press and other mediums" the results of his survey of white and colored soap. Sure enough it was only a few weeks later that there emanated a mimeographed statement sent broadcast to soap-lubbers and headed Physicians Draw Color Line in Soap—White Soap Triumphs Over Colored in National Survey. Then followed a two-and-a-half page article written in the most approved inquiring reporter style and said to be Authorized by F M Goodchild M D, 25 West 45th Street New York City (this was the address of Mr Percival White of White and Parton Inc). Dr Goodchild's "story" was to the effect that he had received replies on the subject of white and colored soap from 205 physicians and nurses although just what proportion of the 205 were physicians and what proportion were nurses was not stated. On this group described as medical authorities 199 reported that they had noticed foreign matter in colored soap while they had found white soap generally free from it while only 6 of the same group reported that they found no harmful ingredients in colored soap.

Dr Goodchild's article stated further that "most of the health officers and physicians who expressed themselves believed that colored soap predominated in producing harmful effects," such effects including dehydration dermatitis or other skin trouble, roughness, dryness or chapping. The white soap, on the contrary, was not observed to disturb the skin. In order doubtless, to lend an air of verisimilitude to an otherwise bald and unconvincing statement, Dr Goodchild gave the names and addresses of forty-nine persons who he claimed had favored white soap among these were several physicians who hailed from various parts of the United States. From the east there were six physicians listed, coming from the states of New York, Maryland (two), Vermont, Rhode Island and Ohio. In the middle west nine physicians succumbed to the questionnaire—three from Illinois, two from Michigan, three from Missouri and one from Indiana. Only two states in the west furnished men who answered Dr Goodchild's letter—California and Colorado. These, with one physician from West Virginia completed the list. The remaining names out of the forty-nine given were those of laymen, some of them alleged to be registered nurses, others superintendents of hospitals, sanatoriums and infirmaries. Summed up according to Dr Goodchild's release, 'one hundred and sixty-three medical authorities' were said to have registered themselves in favor of white soap and only seven for colored. Which must have been very satisfactory for Dr Goodchild or Mr White.

As already stated, Dr Goodchild's interest in the question of the color of soap seemed to extend from March 1930 until May 1930. By October 1930 this inquiring medical reporter had turned his attention to cooking fats, with the very obvious effort to accumulate data to prove that vegetable fats are superior to animal fats for cooking purposes. This time Dr Goodchild's questionnaire was sent on stationery bearing his name and not that of Mr White. However the address was 25 West 45th Street, the address of Percival White and White and Parton Inc. Was it a case of "the voice is Jacob's voice, but the hands are the hands of Esau?" Dr Goodchild's vegetable-fat questionnaire went, in addition to physicians also to those connected with educational institutions such as those in charge of home economics departments of universities and colleges. The leading character of the doctor's questions can best be brought out by quoting verbatim one or two of them.

Do you agree that vegetable fats are more wholesome than animal fats because they are cleaner and sweeter and do not so readily undergo decomposition changes?

Do you agree or disagree with that medical opinion frequently expressed that vegetable fats are more digestible than animal fats?

In your opinion are there certain diseases in which a vegetable diet is very important? If so is gastric ulcer one of them and what others could you mention?

Just what results Dr Goodchild got in his vegetable-fat questionnaire, we do not know, as we were not favored with any mimeographed or other material sent out either by Dr Goodchild or his employers—if any—on the subject.

Two years later, in October, 1932 Dr Goodchild had returned to his first love, soap and was again circularizing physicians particularly dermatologists. The doctor was still using stationery bearing his name but his address had changed from 25 West 45th Street to 130 West 42d Street. From the letter sent to physicians, it appears that Dr Goodchild was greatly concerned over the fact that 'the claims of certain soaps for medicinal and antiseptic qualities are greatly exaggerated.' He gave it as his opinion, and it is an opinion that all rational people will agree with, that the main function of soap is to cleanse. This was the doctor's thesis and 'in the interests of enlightening the public on the real facts,' he was writing to the various physicians and 'other leaders in the field' not it seems, in order to get an unbiased expression of opinion but as he admitted in the introduction to his questionnaire, to obtain authoritative confirmation of the thesis already laid down. Here again the doctor's questions were strictly leading in character, thus:

Do you agree that all soaps have antiseptic action regardless of the addition of any special ingredients?

Do you agree that the main function of soap is to cleanse not to cure?

Do you agree that to be suitable for general daily use a soap should be pure, mild and neutral?

Just how many replies Dr Goodchild got and whether they fitted in with the problem that he had we have no means of knowing. We do know that one well-known dermatologist in the east notified Goodchild very properly that when he gave expert opinion to reputable commercial concerns, he always charged an adequate fee for such work.

In his present questionnaire, Dr Goodchild abandons what might be called the chemical field—soap and vegetable fats—and enters the mechanical field—motor cars. He is still writing on stationery that carries his name, but the present address given is Room 1516, 1250 Sixth Avenue, New York City. He writes to the physician and asks him, 'as a leader in your field for his views on the individual springing of automobile wheels or knee action,' as it is sometimes called." Dr Goodchild then goes on to state the various alleged good points on this improvement in motor car construction recently pioneered in by General Motors. After detailing the virtues of the improvement—presumably with the idea that the recipient of his letter may realize that Dr Goodchild wants a favorable report—the doctor states that he is 'personally much interested in this development' and asks the doctor to whom he writes whether he does not 'agree that this development is worthy of approval.' He closes his letter with the statement that unless the physician to whom he writes advises to the contrary, he plans to use the physician's name and statements for publication, "along with those of other leaders."

After this article was in type and ready to go on the press the Bureau of Investigation learned that Dr Franklin M. Goodchild is conducting his "survey" in connection with the so-called knee-action in motor car construction for Mr Percival White, marketing counsellor, 1250 Sixth Avenue, New York City.

PRODUCTION OF ENDOMETRIAL GROWTH IN CASTRATED WOMEN

To the Editor.—In the discussion of our second experiment described under the title "Production of Endometrial Growth in Castrated Women: The Minimum Dosage of Theelin That Is Required" (*THE JOURNAL*, November 4, p. 1466), Dr Emil Novak states that the method has been used, as Dr Werner and Dr Collier know, particularly by Clauberg and Kaufmann in Germany.

The statement by Dr Novak is ambiguous. While we were the first to produce the growth phase and uterine bleeding among other phenomena, in the uterus of castrated women by the use of theelin, one might infer from his discussion that this is not the fact. We believe that Dr Novak did not intentionally wish to leave this impression. We feel that he wished to convey the fact that Dr Kaufmann has also done work of this nature and has produced the premenstrual endometrium but not until after we had completed and published an account of our work with theelin in a preliminary report in the *Proceedings of the Society for Experimental Biology and Medicine* in June, 1932.

As proof of the foregoing statement regarding the priority of our work, we cite the article of Dr Kaufmann published in the *Zentralblatt für Gynäkologie* in October 1932 in which he reports four experiments performed by him:

EXPERIMENT 1.—In 1928 he injected 2,320 mouse units of folliculin into a castrated woman over a period of twenty-two days. He states as a result of this treatment that he was unable to demonstrate any effect on the endometrium of this patient.

EXPERIMENT 2.—In 1930 he injected 21,500 mouse units of Brunsthormon over a period of thirty-two days and 42 units of corpus luteum hormone. He states that curettage following this experiment failed to show any endometrial effect.

EXPERIMENT 3.—In February, 1932 he injected 100,000 units of progynon benzoate in a period of ten days. He states that again he was unable to produce a functioning endometrium.

EXPERIMENT 4—In June 1932, he injected 10 000 units of progynon benzoate daily for twenty-one days (total 210 000) this was followed by seven daily injections of 5 rabbit units of corpus luteum hormone. He was successful in producing a premenstrual endometrium for the first time by this experiment.

As regards work by Carl Clauberg, an article was published by him in the *Zentralblatt für Gynäkologie*, Oct 8 1932, entitled 'The Action of the Luteal Hormone the Specific Hormone of the Corpus Luteum, on the Human Uterus'. In this article he remonstrates with Dr Kaufmann for having claimed priority, but he admits not having published his work up to that time.

In contrast to this work by Kaufmann, we began our first experiment, Jan 10, 1932, using five castrated women, four of them with intact uteri, while Kaufmann used one castrated woman. During the first twenty-eight day period each patient received 200 Allen-Doisy rat units of theelin daily. Curettements were done before beginning treatment and each week thereafter for three weeks. At the end of two weeks we were able to show marked endometrial growth in all four patients and uterine bleeding during and at the end of the experiment.

This experiment was completed April 22 1932, and reported at the St Louis University seminar in May, 1932, a preliminary report was published in the *Proceedings of the Society for Experimental Biology and Medicine* in June, 1932, at which time Kaufmann was beginning his first successful experiment on one castrated woman, the report of which was not published until October, 1932. Our complete report was accepted for publication in *THE JOURNAL* in September, 1932, and published in *THE JOURNAL*, March 4, 1933.

USE OF ERGOT TO CONTRACT CAPILLARIES IN PURPURA

To the Editor—Recently we have had a patient at Grady Hospital suffering from thrombocytopenic purpura hemorrhagica, probably resulting from intravenous arsenic. He was bleeding continuously from the mucous membranes. There were many large purpuric spots over the body surfaces. The blood examination revealed 2 000 000 red blood cells, 5 000 white blood cells, 65 000 platelets and clot retraction sixty minutes plus.

Repeated transfusions gave temporary support yet it seemed that he would bleed to death in spite of all medication.

Finally we administered to him ergot in 1 drachm doses every four hours and solution of pituitary 0.5 cc hypodermically. Following the first two doses of ergot and one hypodermic of pituitary the bleeding diminished. After twenty-four hours slight bleeding again occurred. The medication was repeated another transfusion was given, and after this his recovery was rapid and progressive. He is now well.

The ergot and solution of pituitary were suggested by me because I have long felt that the pathologic physiology must be intimately related to the capillary bed as well as to the platelet deficiency. It is a well known fact that cessation of hemorrhage depends on the contraction of the vessel wall in connection with other factors. It seemed reasonable that if the capillary walls could be contracted the bleeding might be stopped and to do this the ergot and the solution of pituitary were used. In the one instance the result was gratifying. It may be that there is some equal ratio between capillary contraction and platelet efficiency—that is a widened capillary plus deficient platelets would inhibit the hemorrhage defense, whereas a contracted capillary would be enabled to structure even with a deficient platelet.

This letter is written so that you may describe this method of treatment for the benefit of other physicians who have such cases. I am anxious to know whether others obtain similar results from this procedure.

Heretofore, these patients have been treated with transfusions and other supportive measures. A few spleens have been removed. The mortality has been most discouraging.

The pharmacologists seem to be in dispute as to whether ergot contracts the capillaries or not. It is agreed, however, that the smaller vessels with muscular walls are affected. This may in time aid in contracting the smaller terminals. Solution of pituitary is believed to contract the smaller arterioles and capillaries.

Pathologist, Grady Hospital

HISTORICAL ASPECTS OF ENZYME INVESTIGATIONS

To the Editor—THE JOURNAL has presented an editorial discussion of the historical aspects of enzyme investigations (The Centenary of the Discovery of Diastase, November 11 p 1564) which I have read with great interest. Certainly all workers in this field are pleased to see the emphasis placed on the application of this study to the basic medical sciences.

Priority as regards the first scientific description of enzyme activity is apparently not a matter of general agreement and I should like to call attention to some early observations that are quite commonly overlooked. Practically all books on the subject, for instance, place the priority with Dubrunfaut and with Payen and Persoz in 1830 and 1833, respectively, and this has naturally been accepted in the editorial mentioned. The first description of a practical preparation of an active 'diastase' product was, no doubt, that by Payen and Persoz. However, in referring to the first observation of enzyme activity, usually no reference is made to the report by G S C Kirchhoff, read before the Royal Academy of St Petersburg in 1814, 'Ueber die Zuckerbildung beim Malzen des Getreides, und beim Bebruehen seines Mehls mit kochendem Wasser' (*J f Chemie u Physik*, Schweigger's, Nuremberg 14 389-398, 1815). An English abstract of this report was as follows:

A glutinous constituent is separated from wheat meal by washing and is mixed with a paste of potato starch. The paste stiffens soon the appears and a sugar is formed. The yield of sugar is markedly affected by the experimental temperature a temperature of 50 to 75 appearing most favorable. The syrup has the sweetness of malt syrup is fermentable and is partially soluble in alcohol. The soluble component crystallizes from alcohol in very small white crystals. The insoluble component dissolves in water is not precipitated by an infusion of nutgalls and appears to be a modified form of starch. The active glutinous material is almost entirely recovered by filtration. The filtrate is capable of partially converting a fresh quantity of starch. Dilute sulphuric acid completely prevents conversion of starch by the gluten. KOH also deprives the gluten of its activity. Concludes that the formation of sugar in malt is explained and that a starch-sugar transformation is a necessary step in the alcoholic fermentation of amylaceous materials.

This article can be interpreted to include the aspect of separating a crude enzymic agent a recognition of its catalytic nature and a rough description of its optimum conditions of activity. Although I have emphasized this priority in two books, 'A Comprehensive Survey of Starch Chemistry' and 'Enzyme Action and Properties' it has not been recognized by some subsequent books on the subject. This is probably not based on any discrimination or conflicting interpretation but merely on the relative inaccessibility of the reference in question. Apparently the only available set of this journal is in the New York Public Library, at least in America.

Having spent a good deal of time on this point I was interested to note that priority was really given to Kirchhoff in 1814 as compared with 1830 or 1833 and after that

the more ready accessibility of the references to Dubrunfaut and Payen and Persoz simply displaced the priority due Kirchhoff

Again may I emphasize my agreement with the spirit and general context of the editorial mentioned

SENSITIZATION TO NEOARSPHENAMINE

To the Editor—A woman aged 35 acquired syphilis and came to me with a secondary rash condylomata and a 4+ Wassermann reaction. I gave her 0.3 Gm of neoarsphenamine the first time and 0.45 Gm the next. The night of the second injection she had chills and fever which recurred daily until a morbilliform rash appeared five days later. I then put her on 0.5 Gm of sodium thiosulphate every two days and the rash is almost gone. I am asking you for a complete outline for her further treatment. Shall I turn to bismuth and how much shall I give? May I ever use neoarsphenamine again and if so in what dosages? Is mercury indicated and if so in what form and dosages? Please answer this as soon as possible as I would like to continue this treatment without delay. Kindly omit name.

M D Pennsylvania

ANSWER—It is impossible to be sure at present whether this patient has been permanently sensitized against neoarsphenamine. Morbilliform rashes may or may not be the precursors of an exfoliative dermatitis and an expression of permanent sensitization. In view of the fact that the patient has a recent syphilitic infection, it is of the utmost importance to determine this point as promptly as possible, if she is not permanently sensitized, the total duration of her treatment may be much shorter and the hope of an ultimately successful outcome much better than if treatment must be carried on with the heavy metals alone.

There should be no interruption in the continuity of treatment because of this reaction, intramuscular injections of bismuth salicylate, 0.2 Gm suspended in oil, should be started at once and continued weekly for six weeks. Toward the end of this course of bismuth therapy the sensitivity of the patient for the arsphenamine (including arsphenamine and silver arsphenamine as well as neoarsphenamine) should be tested by means of a patch test (technic described by Schoch, *THE JOURNAL* April 16, 1932, p 1367). If this test is positive (erythema and vesiculation appearing in the tested area in from twenty-four to forty-eight hours), no further arsphenamine may be administered at any time, the patient is permanently sensitized. While a positive patch test indicates sensitization however, a negative test does not exclude it. Further work with the test has shown that not infrequently it may be negative in an individual who is definitely known to be sensitive.

If the patch test is negative, sensitivity should be tested by cautious intravenous testing. For this purpose, a different arsphenamine product from that originally used should be chosen since in a few instances, sensitization may be actually drug specific rather than group specific. In this instance, silver arsphenamine is the drug of choice for this purpose. The initial dose should be minute 25 mg (0.025 Gm). The patient should be carefully observed and interrogated for the possible appearance of four phenomena generalized itching in the absence of a skin rash the appearance of any skin eruption fever and malaise—a knocked-out feeling out of proportion to the size of the dose administered. If any of these phenomena are present sensitization may be assumed and the arsphenamines must be permanently discontinued. If none of them are present the dose may be cautiously increased each week by equally small increments (0.025 Gm), until either evidences of toxicity appear or an average therapeutic dose is reached. Thus it will take about ten weeks of careful dosage increase—0.025 0.05, 0.075 0.1 Gm, and so on—to attain the therapeutic dose of silver arsphenamine of from 0.2 to 0.3 Gm. The appearance of toxic phenomena (itching dermatitis fever, prolonged malaise) at any time is a signal for the end of all attempts at arsphenamine therapy.

During this course of intravenous testing, it is desirable also to perform frequently repeated leukocyte and differential counts. Leukopenia especially if accompanied by a decrease in granulocytes is a warning of impending serious trouble so also is eosinophilia, even if the total white count remains normal.

If either the patch test or the cautious intravenous test already described shows that the patient is sensitized, further treatment must consist of the heavy metals alone. These also should be given continuously if possible, the best method being courses of intramuscular injections of an insoluble bismuth salt, preferably the salicylate alternating with courses of mercury byunction. Under these circumstances the total duration of treatment must be a minimum of three years instead of the average of from fifteen to eighteen months if an arsphenamine can be used.

The spinal fluid should be tested as a routine in any case at the end of about six months of treatment. Should it prove to be positive, it is worth while noting that arsphenamine sensitive patients may be given tryparsamide, a pentavalent drug especially valuable in neurosyphilis, without danger of producing dermatitis.

Incidentally, some workers feel that sodium thiosulphate is of no value whatever in poisoning with the arsphenamines or with other metals. Calcium is probably much more effective.

TENDON TRANSPLANTATION AFTER CUTTING POSTERIOR INTEROSSEOUS NERVE

To the Editor—Assuming that the posterior interosseous nerve is cut at a point about two inches below the radial head or at the radial head is there any tendon transplantation operation or any operation that will restore extension at the metacarpophalangeal joints and phalanges? Please omit name.

M D New York

ANSWER—The subject of peripheral nerve injuries and their treatment received a great stimulus during the World War from the efforts of Sir Robert Jones, Sir Harold Stiles, C. L. Starr, Arthur Steindler, Harry Platt, Dean Lewis, Delageniere, Walther, Tinel and Binesty.

Failures or partial failures after operations on the musculospiral nerve have been successfully treated by tendon transplantation. The operation of Sir Robert Jones of Liverpool consists in the transplantation of the (1) pronator radii teres into the extensores carpi radiales longior and brevior (2) flexor carpi ulnaris into the extensor communis digitorum and extensor longus pollicis, (3) flexor carpi radialis into the extensor ossis metacarpi pollicis and extensor brevis pollicis.

The results of this operation are striking, a useful and strong hand being obtained—a hand that can be utilized for most of the ordinary occupations. On page 18 of his little book called 'Notes on Military Orthopaedics,' published by Cassell & Co Ltd London Sir Robert Jones states that in cases of musculospiral injury the uncontrolled action of the flexor group causes the fingers to curl into the palm and the hand to become useless. In such a case (a) the flexor carpi radialis and the flexor carpi ulnaris can be transplanted into the paralyzed extensor of thumb and fingers and, (b) in addition, the pronator radii teres may be sutured to the two radial extensors.

Jones recommended transplantation of the pronator radii teres and the radial and ulnar flexors in musculospiral paralysis and describes the technic as follows. With the forearm midway between pronation and supination an incision is made along the radial border of the forearm in its middle third. Under cover of the tendon of the supinator longus the pronator radii teres will be found where it becomes inserted into the outer border of the radius. From this it is detached and is then inserted into the tendons of the extensor carpi radialis longus and brevis which he closely applied to it on the dorsal surface.

A horseshoe incision, with the convexity resting on the back of the carpus with the two straight sides extending along the radial and ulnar borders, is now made. Through the lateral aspects of this incision the tendons of the carpi ulnaris and radialis are identified and are detached from their insertions as near the carpus as possible.

The tendons are brought round the ulna and radius respectively in a very slanting fashion and are then attached to the extensors of the fingers and thumb the flexor carpi ulnaris being attached to the extensor longus digitorum tendons of the three inner fingers and the flexor carpi radialis to those of the thumb and index finger.

When the lesion is below the origin of the posterior interosseous nerve, the radial extensors of the wrist are intact and the transference of the pronator radii teres is of course, unnecessary. Stiles modified the original operation by inserting the tendon of the palmaris longus into the extensor pollicis longus the flexor carpi radialis into the extensor primi internodi pollicis and the extensor ossis metacarpi pollicis, and the flexor carpi ulnaris into each of the extensor digitorum tendons. The hand is immobilized for two weeks in dorsiflexion the wrist being kept almost at a right angle and the metacarpophalangeal and interphalangeal joints being only slightly palmar flexed.

to avoid subsequent stiffness. The after-treatment consists of daily massage and electrical stimulation. Recovery is usually complete in from eight to ten weeks, and the position of extension must be maintained until there is return of voluntary function.

PERTUSSIS VACCINE

To the Editor—What is the value of pertussis vaccine as a preventive measure and as a measure for reducing the severity of the attacks? Which vaccines can be counted on as reliable? Please omit name

M D Rhode Island

ANSWER—There is considerable difference of opinion among physicians with regard to the value of pertussis vaccine either as a preventive or as a therapeutic measure. Many believe that pertussis vaccine prepared entirely from the Bordet bacillus is a distinct aid as a prophylactic. Some of the vaccines used for the treatment of whooping cough are termed 'pertussis combined' and contain, in addition to the Bordet bacillus, staphylococci, streptococci, pneumococci, influenza bacilli and Micrococcus catarrhalis. Though many physicians favor the use of vaccine in the treatment of whooping cough, there seems to be little doubt based on numerous reports and investigations that have been carried on in the past that the average stock vaccine supplied for the treatment of this disease exerts little, if any, influence on the course during the paroxysmal stage.

PHYSIOLOGIC BASIS FOR HYPERACTIVE CHILD

To the Editor—Can you give me any information regarding the physiologic basis for the overactive or hyperactive child? Please omit name

M D Rhode Island

ANSWER—A physiologic basis for the overactive or hyperactive child may be sought in the autonomic nervous system, the endocrine glands or the constitutional makeup of the individual. Existing knowledge of the physiologic regulation of the vegetative nervous system is in a highly speculative state. However, in many of these overactive children an accompanying increased salivary gland secretion, increased intestinal motility and vasomotor instability can lead one to suspect a hyperactivity in the autonomic system. The relation of the endocrine glands to overactivity in children is founded on better known physiologic facts. The influence of the thyroid secretion as, for example, the hyposecretion in cretinism with accompanying dullness and sluggishness, and the overactivity of the hyperthyroid are examples of knowledge in this field. The endocrine influence in the growing child especially at the time of puberty, is well known. A physiologic increase in systolic blood pressure at this period often to astonishingly high values, is based on physiologic endocrine influence. The constitutional factor is most important. Overactive children are most often the offspring of highly strung emotional unstable parents. A child who inherits an unstable nervous system or a temperamental emotional disposition can hardly be expected to be dull, inactive and phlegmatic in his reaction. Environment also may tend to produce or aggravate overactivity. Calm placid surroundings constitute the ideal environment for every child. A child with an overactive tendency will show more pronounced and aggravated symptoms in the overactive direction in a disturbed and turbulent home life.

THERAPEUTICS OF CALCIUM

To the Editor—What are the more common indications for calcium therapy at the present time? Please omit name

M D Rhode Island

ANSWER—Calcium carbonate is employed as a vehicle for antacid action.

Calcium is employed as a vehicle for ions with a systemic purgative tendency, e. g. calcium chloride as a diuretic.

Calcium is used to prevent calcium impoverishment of the system, for example in pregnancy and lactation and in childhood unless the calcium is taken in the form of milk (1 quart daily).

In the treatment of acid diarrhea calcium carbonate not only neutralizes the acid and thus checks the irritability but also

raises the amount of calcium available for absorption, which may be of importance in celiac disease of infants and sprue in adults.

In tetany and spasmodophilia there is a deficiency in available calcium ions owing to alkalosis or parathyroid deficiency. Hence calcium administration is of but temporary value in these conditions, unless the alkalosis or parathyroid deficiency is simultaneously corrected.

The results from calcium salts in inflammatory and non-inflammatory effusions and edemas is generally disappointing, unless the ionization of calcium is at the same time increased, as it may be by the intravenous injection of calcium chloride. Simultaneous salt restriction seems to be especially important for results in tuberculous effusions.

While calcium cannot, in general, be relied on to increase the coagulability of the blood, it may do so in certain conditions, as in the bleeding tendency of the icteric.

The local use of calcium in the form of lime water or of chalk exerts a very mild astringent effect.

STRICTURE OF THE CERVIX WITH HEMATOMETRA

To the Editor—A single woman aged 24 with a normal genital history up to three years ago when she had gonorrhea presented herself today with an amenorrhea of two months. She suspected a pregnancy. During her gonorrheal infection she apparently had had some form of thermal cauterization of the endocervix. She was under treatment for about six months and was discharged as cured. Since her gonorrhea she has menstruated every twenty-eight days up until two months ago but has had an increasing dysmenorrhea. On examination I found her to be normal in every way except that the external os was completely bridged over by epithelium—not the slightest opening could be found. What if any will be the effect on the general health of this individual so long as the occlusion is permitted to remain? Will nature as a result of the occlusion abstain from having her ovulate? Please omit name

M D, Wisconsin

ANSWER—The patient is probably not pregnant but should have an Aschheim-Zondek test to determine this with certainty. The trouble is apparently a stricture of the cervix complicated by hematometra. In the absence of pregnancy, a thorough dilation of the cervical canal is imperative. Otherwise the backpressure of retained menstrual blood will cause hematosalpinx and generalized pelvic inflammation. Ovulation will not cease but sterility usually occurs in these cases unless the stricture is overcome during the early months.

RELATION OF NASAL OBSTRUCTION TO HEART DEFECT

To the Editor—A girl aged 3 1/2 years has had one attack of rheumatic heart disease, has an autumnal hay fever and has frequent colds. Her tonsils and adenoids do not appear to be enlarged. However the septum of her nose deviates markedly to the left at the level of the upper edge of the lowest turbinate bone. The obstruction is so great that even when well she has difficulty in breathing through her nose. She awakens at night frequently because of inability to get her breath but she never breathes through her mouth. The hay fever aggravates the condition greatly. Will not the difficulty in breathing, in time damage her already slightly weakened heart? Under the circumstances is operation to straighten the septum advisable? What sort of operation should be done? Please omit name

M D Michigan

ANSWER—The marked difficulty in breathing is not likely to impair a slightly weakened heart, although it may be distressing from the standpoint of both the patient and the parents. The size of the adenoids should be estimated by finger palpation and judgment drawn not only from the actual size of the adenoid mass but from a comparison between its size and that of the nasopharynx. A small adenoid will markedly block a small nasopharynx and its removal by the same token will much improve the breathing. As to the additional troubles imposed by the deviated septum a child whose difficulties are as great as those described might, in the opinion of many good men be submitted to a septum operation. Such occasions are not frequent of course but from time to time they do occur. As the deviation in these instances is frequently anterior and cartilaginous in nature the removal of just the offending piece of cartilage may solve the whole problem no more tissue being taken out than is absolutely necessary. A skilful operator may avoid removing any cartilage by incising it in such a fashion that it may be swung into proper position and allowed to remain in place. A cautious procedure would consist in first removing the adenoid mass, proceeding to the septum operation only if the risk to give relief.

The frequent cold must be considered a cause of nasal obstruction as this may be due to sinusitis with secretion or to a perennial hay fever or vasomotor rhinitis and the possibilities should be disposed of before surgical intervention is attempted.

RETARDATION OF DEVELOPMENT OF GENITALIA

To the Editor—Thirteen months ago a boy was born as the second child to two healthy parents. The child has developed normally to the present time. A matter of concern both to the parents and to myself is the small size of the penis which protrudes hardly noticeably. Circumcision was performed at 1 week of age revealing the normal glans penis. There seems to be no evidence of hermaphroditism. My prediction is that this will maintain its proportional size that it is more a congenital deformity than a glandular deficiency. Can you throw any light on this subject? Please omit name.

M D Tennessee

ANSWER—The condition referred to is often combined with delayed descent of the testicles, which phenomenon should be investigated. Besides individual variations retardation of development corrects itself frequently with the natural growth of the child. The same holds good in a great many instances with the spontaneous descent of the testicles. Some observers report that in the second year of childhood both these conditions are favorably influenced by the injection of compounds derived from the anterior half of the pituitary body. These compounds may be obtained from any medical supply house.

X-RAYS OR RADIUM IN UTERINE HEMORRHAGE

To the Editor—In the hands of experts which has proved the safer measure to use in uterine bleeding of a young woman x-rays or radium? Please omit name.

M D New York

ANSWER—A few men employ small doses of radium for bleeding but the x-rays and radium both cripple the ovaries and on this account most gynecologists do not favor their use in women under 40. Keene gives 100 mg for not longer than five or six hours, with the thought that the ovaries will not be permanently injured by this small dosage and produces temporary amenorrhea in this way. Those who are less enthusiastic over fractional doses of radium do not, as a rule, favor the x-rays but prefer recourse to operation in case simple palliative measures are of no avail.

Provided ray therapy has been decided on radium is usually given preference over the x-rays, first because a diagnostic curettage may be performed at the same time, and this is usually essential, and also because radium is more direct and more localized in its action and the dosage can be accurately gaged.

HIGH BASAL METABOLIC RATE

To the Editor—Please tell me what a metabolism test of plus 17 for a girl aged 8 means. Please omit name and address.

M D South Carolina

ANSWER—A basal metabolism reading of plus 17 for a girl, aged 8 years, must be interpreted with a great deal of caution. Even when such variables as cooperation and emotion have been ruled out, it must be remembered that this result is not much outside the limits of normal variation. It is well to recalculate such a result on the basis of more than one of the prediction standards available for that sex and age. These standards may yield results in a particular case which differ from each other by more than the reading obtained here. This is partly due to the different criteria on which these standards are based, partly because of the fact that there may occur real differences in temporal and physiologic age and partly because during that decade small differences in age may have great influence on the metabolic rate. In cases like this the basal metabolic rate by any one prediction standard may be useful as a guide to the progress of the case or to the effect of treatment. It should not, however, be allowed to outweigh the clinical diagnosis.

TENDER FEET

To the Editor—A man aged 71 suffers a great deal from tender feet. While he was in the railway service about thirty five years ago both of his feet were frozen but on reaching the hospital his feet were immersed in ice water and he suffered no sloughing or bad after effects. Since that time his feet have been exposed to extreme cold but never frozen. He does not complain of pain unless pressure is applied but of extreme tenderness. Will you please suggest applications that will toughen the skin on his feet? Please omit name.

M D, Oklahoma

ANSWER—The probability is that the trouble is circulatory. Are the feet cold and can a normal pulse be felt in the dorsalis pedis and posterior tibial arteries? Hot foot baths should be followed by the application of an oil. The French advise the use of cod liver oil for this purpose, combined with the administration of small doses of iodides internally. Massage should be done upward with the oil as the patient can stand it. Tobacco should not be used. Loose fitting shoes and wool socks should be worn. A galvanic foot bath for from ten to fifteen minutes several times a day may be helpful.

Book Notices

Infections of the Hand: A Guide to the Surgical Treatment of Acute and Chronic Suppurative Processes in the Fingers, Hand and Forearm. By Allen B. Kassarofsky, M.D., Sc.D., Professor of Surgery, Northwestern University Medical School, Chicago. Sixth edition. Cloth. Price \$6.15. 552 with 216 illustrations. Philadelphia: Lea & Febiger, 1933.

This book has established itself as a classic. It is the work of the best known authority on the subject and presents a complete study of the anatomy, pathology and treatment of infections of the hand. The author has added much new material and radically revised the old. The new material consists of investigations on special infections such as bites and injuries from the teeth, metacarpophalangeal infections, gangrenous infections, and injuries from indelible pencils and cattle hair. Chapters have been added on the function of the hand and the use of splints, and the prophylactic treatment of injuries. Practically every chapter has been brought down to date. In this edition the subject matter is presented with the discussion of the anatomy and the experimental investigation separated from the clinical study. Kassarofsky emphasizes the fact that lymphangitis and suppurative tenosynovitis are still too often unrecognized and improperly treated. In lymphangitis, hasty incision not infrequently leads to unnecessary loss of life. In suppurative tenosynovitis the pathologic condition is not recognized and failure to institute early treatment leads to prolonged illness and permanent disability. The chapter on the use of splints after infections of the hand is highly instructive. The chapter on function of the hand in relation to infections is itself worth the price of the book. The composition, including the printing and the paper is excellent. The illustrations, including line drawings, anatomic dissection, colored diagrams and reproductions of photographs, each and every one of which illustrates at least one point, are instructive. Many of the author's original hand drawings have been replaced by excellent sketches by Tom Jones, who has drawn several illustrations from the author's film on the diagnosis and treatment of infections of the hand. The book should be on the desk of every physician and surgeon. It is indispensable for traumatic surgeons.

Le métabolisme de l'azote. Dépenses besoins couverture. Par Emile F. Terroine, professeur à l'Université de Strasbourg. Les problèmes biologiques VIII. 12 francs. 1p. 12 with 21 illustrations. Paris: Les Éditions Internationales de France, 1933.

This volume presents a detailed survey of the whole field of nitrogen metabolism by a competent authority. Through the excellence of his systematic arrangement the author has succeeded in presenting his subject in a complete and continuous manner without sacrificing the detailed consideration of the numerous constituent problems that together constitute the whole. The material is divided into short sections and paragraphs each with subheads that indicate its content and subject matter. The argument is amply illustrated by tabular data and experimental references to the international literature are made.

The book is primarily academic and not clinical in nature. However, the distinct separation of fact and theory, the extensive use of illustrative experimental data, and the systematic arrangement, which facilitates reference, should make it a valuable addition to the library of the well informed physician as well as to that of the biologist.

Housing and the Community—Home Repair and Remodeling. Reports of the Committees on Housing and the Community. Joseph H. Pratt, M.D., Chairman. Reconditioning, Remodeling, and Modernizing. Frederick M. Felker, Chairman. Edited by John M. Gries and James Ford. Publication No. 8 of the President's Conference on Home Building and Home Ownership. Cloth Price \$1.15. Pp. 291 with illustrations. Washington, D. C.: President's Conference on Home Building and Home Ownership.

This is a careful study of housing, home repair and remodeling with special reference to the relation of housing to health, delinquency, industrial efficiency, safety, citizenship, recreation and education. There is an extensive bibliography with many quotations and abstracts referring especially to housing and crime. The committee displays a praiseworthy caution in drawing conclusions as to the causative relationship between bad housing and bad health, delinquency, industrial inefficiency and crime. The book does point out that bad housing is almost universally related to other unfavorable environmental influences and that it is probably one factor in creating or at least favoring the increase in social maladjustment. It points out the importance of wise financing and planning of housing developments. The book is a storehouse of facts and the conclusions are in most instances sufficiently guarded to indicate that while a strong impression exists that bad housing is bad municipal economy, there is no statistical proof. Perhaps impressions are worth more than statistics in arriving at such a judgment. Particularly valuable is the appendix which contains a home inspection check list by means of which a building can be evaluated by the occupant or prospective purchaser as to its desirability for a home with respect to construction, safety, health, convenience, equipment, fire hazards and probable future value. This is a reference book which every health and social worker needs to read.

Verhandlungen der Deutschen Gesellschaft für Kreislaufforschung VI. Tagung gehalten zu Würzburg am 6 und 7 März 1933. Herausgegeben von Prof. Dr. Bruno Kisch. Paper. Price 10 marks. Pp. 276 with 112 illustrations. Dresden & Leipzig: Verlag von Theodor Steinkopff, 1933.

There are altogether twenty-eight papers in this volume of transactions. In addition there are numerous discussions, some of which are evidently reported in full. The general subject of the meeting was the circulation and the nervous system. The leading paper ("referat") taking up particularly the anatomic and physiologic aspects was by H. E. Hering of Cologne. The leading paper dealing with the clinical features was by F. Kauffmann of Berlin. Among the papers were several dealing with the carotid sinus, a few with the electrocardiogram and with cardiac irregularities. Various phases of blood pressure were also discussed. The president of the society, Professor E. Magnus-Alsen of Würzburg, delivered the opening address, which was largely historical. The volume is useful for reference and is of especial interest to one wishing to know the latest views of our German colleagues on a subject that the president said had been regarded by some as too difficult to be taken up, a fear, however, which he did not share.

The 1933 Year Book of Radiology. Diagnosis. Edited by Charles A. Waters, M.D., Associate in Roentgenology, Johns Hopkins University. Therapeutics. Edited by Ira I. Kaplan, B.Sc., M.D., Director, Division of Cancer, Department of Hospitals, City of New York. Cloth. Price \$7. Pp. 804 with 780 illustrations. Chicago: Year Book Publishers, Inc., 1933.

In this collective review of the year's progress in radiation diagnosis and therapy the authors have excelled their effort of last year to present a readable well arranged sufficiently illustrated summary of recent progress in their respective fields. It would seem to be an indispensable volume for every radiologist and it will be of assistance to every physician who desires to keep abreast of radiologic progress. The attention devoted to foreign literature is gratifyingly increased over the space given to foreign abstracts in the previous volume. Methods employed in radiation therapy are constantly being revised and irradiation is being called on increasingly for the treatment of an ever-growing number of complaints. The field of radiologic physiology, biology and physics still constitutes a challenge to research for the elucidation of many unknown factors. It is apparent

that biologic functions play a more important part than the mere physical variations in the rays produced by voltages of different amount, or by the gamma rays of radium. Additional experience tends to show that longer exposures, perhaps amounting in some selected cases to the whole-body irradiation method of Heublein, are preferable to the shorter more intense, more localized, treatments. It is hoped that the authors may receive sufficient encouragement in their work to insure the annual reappearance of this volume.

Diagnostik und Therapie der Lungen und Kehlkopf-tuberkulose. Von Dr. H. Ulrich, Arzt, Direktor des Tuberkulosekrankenhauses der Stadt Berlin in Sommerfeld (Osthavelland). Second edition. Paper. Price 25 marks. Pp. 389 with 269 illustrations. Berlin: Julius Springer, 1933.

The subject of tuberculosis, like the politics of the day, is undergoing a rapid and striking change and the present edition is practically a new book. After thirty-five pages devoted to pathogenesis and pathology, similar space is allotted to childhood tuberculosis. Physical, radiologic and bacteriologic diagnosis is well discussed. The exudative and productive types of pulmonary tuberculosis as well as hematogenous tuberculosis are described. To treatment, 100 pages is assigned. Specific therapy, chemotherapy and complications have ample sections given them. Laryngeal tuberculosis is discussed satisfactorily in seventeen pages. The section on intestinal tuberculosis is not satisfactory. The psychology of the consumptive is fully discussed. The use of alcohol in treatment is mentioned, and one learns that the author does not advocate its use except for the usual extreme conditions. The Gerson-Sauerbruch-Hermannsdorfer diet is given, and some discussion of gold treatment, to which Ulrich is neutral or mildly opposed. It is interesting to note that he advocates roentgen treatment of forms of productive tuberculosis which are tending to induction. There is no mention of the use of *Bacillus Calmette-Guérin*. A good discussion of surgical measures occupies the last third of the book. It is to be noted that Ulrich does not favor phrenic exeresis but rather emphysema. There are new sections on oleothorax and on plombierung. The book is a good summary of modern German work on tuberculosis and is written in a clear style and well printed. The numerous illustrations are admirable, far better than those usually issued by American publishers. The bibliography is practically all German for only two references are given to foreign literature, one American, one French. In spite of this the author has not overlooked much and to all who read German the book is heartily recommended, for one is impressed by the scientific manner in which the author gives his own experience in sections where his is at variance with that of others.

Histopathology of the Peripheral and Central Nervous Systems. By George B. Hassin, M.D., Professor of Neurology, University of Illinois, College of Medicine. Cloth. Price \$6. Pp. 491 with 229 illustrations. Baltimore: William Wood & Company, 1933.

This textbook is by far the best that has appeared in the recent deluge of works on neuropathology. It is written by a man who has had great clinical experience and possesses an intimate first-hand knowledge of preparations of pathologic material and of the methods by which these preparations were obtained. Although written in a style that sometimes differs from the American idiom, the descriptions of the microscopic slides are so objective that one has the impression that the author wrote them directly from the slides. The illustrations, particularly the photomicrographs, are excellent, and the publishers have done a worth-while job in reproducing them—in fact, the illustrations are much better than one usually finds in a textbook for students. Hassin has several radical theories, for example that the choroid plexuses, instead of secreting cerebrospinal fluid, absorb it. Although he has paid too little attention to experimental evidence and lays too great stress on doubtful pathologic material in this book, he has refrained from emphasizing his radical point of view and on the whole his summaries of disease entities will be clearly understood by the student. The book has perhaps only one fault, which will probably always be found in a pathology written by a clinician: that not enough space is given to the fundamental disease processes and too much space is given to the diagnostic characteristics of all the different diseases. The first part deals with the diseases of the peripheral nerves, the second part with the diseases of the spinal cord, the third part with the diseases of

the brain, and the fourth part (a welcome addition) with the most useful staining methods that are applicable to nervous material obtainable in the routine pathologic laboratory. Hassin's book deserves an enthusiastic reception.

Die Epidemiologie des Typhus abdominalis unter besonderer Berücksichtigung des Bact. typhi flavum. Von Prof. Dr. med. et phil. E. G. Dresel, Direktor des Hygiene-Institutes Greifswald. Heft 1. Mikrobiologie, Immunbiologie und Grenzgebiete. Wissenschaftliche Zeitschriften. Paper. Price 3.60 marks. Pp. 40 with 2 illustrations. Leipzig: Johann Ambrosius Barth, 1933.

German bacteriologists in and about Greifswald have been interested recently in a yellow variant of the typhoid bacillus ("Bacterium typhi flavum"), which they believe to be a more or less saprophytic form" capable of longer life outside the human body than the ordinary typhoid bacillus. In Dresel's opinion the occurrence of this resistant type explains some allegedly obscure facts in the epidemiology of typhoid. It may be questioned whether the sources of infection of typhoid are in reality as confusing as they are assumed to be in this pamphlet.

Nervous Breakdown: Its Cause and Cure. By W. Beran Wolfe, M.D., Director of the Community Church Mental Hygiene Clinic, N. Y. Cloth. Price \$2.50. Pp. 240. New York: Farrar & Rinehart, Inc., 1933.

Psychiatrists seldom use the term "nervous breakdown." The public uses it constantly. So Dr. Wolfe has written a book on psychoneurotic reactions for the public in words it can understand. He is a sympathetic follower of much of what Dr. Alfred Adler has taught. The author's explanation of the "nervous breakdown" as "a valuable unconscious offensive-defensive device designed to save face before personality disaster occurs" will not fit all cases but is accurate in enough instances to justify amply the text that follows. The seven chapters are on causes, symptoms, cases and cures (three chapters), plain words to patients, and creative self-realization. The book is exceedingly well written, contains a fund of excellent advice, is well balanced in its scientific outlook and is distinctly practical. It shows ample evidence of orderly thinking and presents suggestions in a common sense and usable fashion. It can be unreservedly recommended to the layman.

Les arthrodèses dans la coxalgie. Indications techniques, résultats éloignés. Par Louis Buisson. Préface du Professeur Sorrel. Paper. Price 20 francs. 1p. 109 with 9 illustrations. Paris: Masson & Cie, 1933.

The author describes the indications, contraindications, general principles, complications, technique and end results in cases of tuberculous hip disease treated by arthrodesis. He reports twenty-nine old cases occurring in adults. He describes eight old cases of arthrodesis for tuberculosis of the hip in the process of evolution in infants. The illustrations are well reproduced.

Bone Growth in Health and Disease. The Biological Principles Underlying the Clinical Radiological and Histological Diagnosis of Perversions of Growth and Disease in the Skeleton. By H. A. Harris, D.Sc., M.B., B.S., Professor of Clinical Anatomy, University College and University College Hospital, London. Cloth. Price \$10.00. 1p. 248 with 201 illustrations. New York & London: Oxford University Press, 1933.

This book is the outgrowth of articles published in such periodicals as the *British Journal of Radiology*, the *Journal of Anatomy* and the *Lancet*. Those who have read the original articles will be glad to see them in book form. The author who is an authority on the subject offers a wealth of material in presentable form. The book is divided into three parts on lines of arrested growth in the long bones in childhood, bone growth with special reference to deficiency diseases and significance of the fundamental processes of growth and repair in skeletal disease. First are recorded clinical and experimental researches on the growth of bone. In the first part the researches are based on a study of arrested growth in disease and in experimental animals. The author indicates the application of the results of this study to the elucidation of certain clinical facts in diseases of children and animals and thus forms the main portion of the second part with special reference to the correlation of roentgenographic appearance and histologic structure. The third part contains recent investigations in which Harris demonstrates the distribution of mucopolysaccharides in cartilage. The distribution of glycogen in relation to plasma plate and the reaction to primitive myophascic character that accompany the age changes in the skeleton are briefly

index of the work to be pursued in the future. The author states that the romance of bone growth is not yet exhausted. The manifestation of disease in bone, the registration of lines of arrested growth in the long bones, the phenomenal response of certain deficiency diseases to vitamins, the age changes in bone, and the extent to which the child can grow out of disease conditions, still present fundamental problems in clinical research and biology. The illustrations, including line drawings, reproductions of photographs and roentgenograms, gross sections and microscopic sections are instructive and beautifully reproduced. The author's experimental work is given and a good bibliography is appended. This book should be of interest to every pediatrician and orthopedic surgeon.

Medicolegal

Malpractice: Abandonment of Patient After Operation.—The plaintiff sued the defendant-osteopath for malpractice. He charged (1) that they had erroneously diagnosed his condition as appendicitis and had performed a useless operation, (2) that they so carelessly and negligently performed the appendectomy as to cause a stoppage or obstruction in his bowels, and (3) that they failed to render him the proper post-operative care. At the close of the plaintiff's evidence the trial court ruled that the evidence was insufficient to justify the submission of the case to the jury. Subsequently on appropriate motion by the plaintiff, the trial court revised its ruling and ordered the defendants to stand trial on the charge of negligent postoperative care. From this revised ruling the defendant Laughlin appealed to the Supreme Court of Missouri, division I. The evidence, said the Supreme Court, must be viewed in the light most favorable to the plaintiff. Briefly, the plaintiff, Aug. 28, 1928, consulted Sites, an osteopath, for relief from a severe pain in his abdomen. Sites diagnosed the ailment as appendicitis and advised an immediate operation which was performed by Laughlin, another osteopath. After the operation the plaintiff began vomiting and continuously suffered intense pain in his abdomen, which was "swollen as tight as a drum." He remained in the hospital thirteen days, during which time he had no bowel movement and vomited fecal matter "every day or so." He complained to interns and nurses and asked that Laughlin be called but the latter did not appear. Apparently nothing was done during his stay in the hospital to relieve the plaintiff's condition. On September 10 he was discharged from the hospital and returned to his home, where Sites continued to treat him. Five days later his condition becoming worse, a nonsectarian practitioner was summoned and a diagnosis of intestinal obstruction was made. Finally a passage of the bowels was induced, September 29, the thirty-first day after the operation.

In the absence of an agreement, understanding or notice to the contrary, said the Supreme Court, when a physician is employed to perform an operation the relation of physician and patient continues until ended by the mutual consent of the parties or by the physician's withdrawal after reasonable notice, or by the dismissal of the physician by the patient or by the cessation of the necessity that gave rise to the relation. The physician must not only use reasonable and ordinary care and skill in performing the operation but during the continuance of the relation of physician and patient he must exercise ordinary diligence in the subsequent treatment. He must give or see that the patient is given such attention as the necessity of the case demands. Laughlin continued the Supreme Court was in charge of the case from the time the plaintiff entered the hospital and during the time he remained there. There was no agreement limiting his service to the mere performance of an operation or any agreement, understanding, or notice to the plaintiff that Laughlin would not thereafter either attend and treat the plaintiff or see that such proper care and treatment as the case might require were received. The plaintiff placed him in Laughlin's hands, submitting to and relying on his knowledge, skill and judgment. After the operation the plaintiff remained under Laughlin's care, relying on his judgment, and the relation of physician and patient continued.

Laughlin contended that the question whether or not requisite degree of care and skill were exercised in treating the plaintiff is to be tested by the general rules and principles of osteopathy, not by the principles of nonsectarian medicine. This argument, said the Supreme Court, has no application to the facts presented here, for the plaintiff's action does not proceed on the theory that some improper method, system or course of treatment was used, but that after the operation Laughlin negligently failed to discover and observe the plaintiff's condition and symptoms and negligently failed to give, or cause to be given, the attention and care which such condition demanded. The intestinal obstruction that developed immediately after the appendectomy continued to grow worse. The distended abdomen, the intense suffering, the absence of any bowel movement, and the vomiting of fecal matter should have indicated a serious intestinal obstruction. It is apparent that this condition was such as to have been readily discoverable by the exercise of that reasonable degree of care, examination and attention which it was incumbent on Laughlin as the physician in charge of the case, to exercise. The plaintiff's evidence concluded the court, was sufficient to justify submission of the case to the jury to determine whether or not Laughlin negligently failed to exercise reasonable care toward the plaintiff after the operation and whether the alleged nonattention and failure to observe and discover his condition and administer or give treatment calculated to correct or relieve such condition proximately contributed to aggravate intensify and prolong the plaintiff's ailment. The action of the trial court in awarding a new trial to the plaintiff was accordingly affirmed.—*Reed v. Laughlin* (Mo.) 58 S. W. 2d 440

Malpractice Gangrene Following Treatment of Fracture—The plaintiff, a girl 12 years old, fell from a swing and broke both bones of her left arm, just above the wrist. The ends of the bones extended through the skin and became covered with dirt. She was taken to a hospital and there placed under the care of the defendant-physician. Two days thereafter gangrene set in and on August 16 it became necessary to remove the arm at the shoulder. An uneventful recovery followed. In this suit against the defendant for malpractice, the plaintiff claimed that the defendant was negligent in rendering treatment in the first instance in that he used dry dressings when he should have used wet and that, while he dressed the arm on the morning of August 15, he did not again see the patient until he was called by the supervisor of nurses at the hospital about 6 a. m., August 16, and that no other competent persons examined the patient in the meantime. The trial court gave judgment for the plaintiff and the defendant appealed to the Supreme Court of Alabama.

It was claimed that on the afternoon of August 15 manifest signs of the infection were in evidence which would have been discovered by the defendant had he examined her that afternoon or night. The defendant contended that he did examine the patient several times, and the hospital chart showed that he made an examination on the afternoon of August 15. There was, however, substantial evidence to the contrary. The expert witnesses were in accord, said the Supreme Court of Alabama, that the circumstances of the accident known to the defendant suggested the probabilities of gangrene, known to be very dangerous. Such knowledge, all admitted by the defendant, demanded frequent examination and radical treatment. There was substantial evidence that on the afternoon of August 15 the wound emitted a strong and offensive odor and that the patient had fever and was restless. Early the following morning the infection had extended past the elbow. That circumstance and the evidence of the symptoms on the preceding afternoon and night justify an inference that the infection on that afternoon could and would have been detected by a competent person, said the court and prompt and efficient treatment would have probably stopped its progress and prevented the necessity of amputation. When a physician undertakes to treat a patient whose condition, known to the physician, is such that without continuous or frequent expert attention injurious consequences may result, he must either render such attention himself or see that some other competent person does so. The question of the defendant's negligence was a fair issue for the jury. The trial court, however, refused to charge the jury that if

they believed the evidence they could not find for the plaintiff because the defendant used dry bandage in dressing the plaintiff's injury. This was error, said the Supreme Court. The gravamen of the complaint is negligence, not want of skill. Where there are various recognized methods of treatment, the physician is at liberty to follow the one he thinks best and is not liable for malpractice because expert witnesses give their opinion that some other method would have been preferable. The experts in this case all agreed that wet and dry dressings in such cases are both used by skillful physicians and that standard authorities approve them both. It is largely in the sound discretion of the surgeon in charge of the case. The defendant was shown to have been a competent surgeon and used the method adopted by him with care and skill, and the wound continued to drain to the last and did not seal up. This is the result the best process was expected to secure. For using dry bandage the defendant is not chargeable with want of due care or negligence, and the refusal of the trial court to charge the jury as requested constituted a prejudicial error to the defendant. The judgment of the trial court, therefore, was reversed and the case remanded.—*Jackson v. Burton* (Ala.) 147 So. 414

Society Proceedings

COMING MEETINGS

American Academy of Orthopedic Surgeons, Chicago, Jan. 8-10. Dr. Philip Lewin, 104 South Michigan Blvd., Chicago, Secretary.
Annual Congress on Medical Education and Licensure, Chicago, February 12-13. Dr. W. D. Cutter, 535 North Dearborn Street, Chicago, Secretary.

CENTRAL SOCIETY FOR CLINICAL RESEARCH

Sixth Annual Meeting held in Chicago Oct. 27 and 28, 1933

(Concluded from page 2078)

Studies on Surgery of the Inferior Vena Cava

DRS. WALTMAN, WALTERS and JAMES T. PRIESTLEY, Rochester, Minn. Experimental and clinical studies were made following incision and suture of the inferior vena cava. In the experimental studies on dogs, a portion of the vena cava was removed and the vessel repaired with specially prepared silk sutures. Subsequently, at varying intervals, necropsy was performed on the dogs to ascertain the status of the healing processes in the vena cava and to discover any possible evidence of thrombosis or embolism. Serial microscopic preparations made from the vena cava at the operative site evidenced the reparative reaction in the wall of the vein, starting with early fibroblastic proliferation in the adventitia and ending with complete endothelialization of the intimal layer. In four clinical cases the inferior vena cava was opened for the removal of papillary projections of a right renal neoplasm, or during mobilization of a densely adherent kidney. In each case hemostasis was satisfactorily obtained by suture in some cases and by the application of hemostats in others, without the necessity of ligating the vena cava.

DISCUSSION

DR. MORRIS H. NATHANSON, Minneapolis. I should like to ask concerning the possibility of operating on the inferior vena cava within the pericardium. Several years ago I reported some cases of therapeutic pneumopericardium before this society. In one case the air did not appear on the right side of the heart which indicated that there were some adhesions in this region. The patient later developed a cardiac decompensation with only slight dyspnea but marked liver enlargement and ascites. I considered that this might be due to adhesions about the inferior vena cava and this was found at autopsy. Were the possibilities good for surgical intervention in this case?

DR. ARGO J. BEHN, Cleveland. I should like to ask the authors whether they have had evidence of thrombosis.

DR. J. T. PRIESTLEY, Rochester, Minn. I have had no experience with clinical surgery of the vena cava for adhesions.

about the pericardium. In animals the vessel can be approached quite satisfactorily and can be manipulated with a certain amount of success and satisfaction, in this region. Very few satisfactory results following pulmonary embolectomy have been reported. If conditions are favorable, the vena cava might possibly be operated on at that point. I endeavored to discuss the evidence of healing in the vena cava and to discover any possible evidence of thrombosis or embolism. No pulmonary emboli were discovered in any animal, however, in several instances there was a small adherent thrombus at the operative site.

Focal Infection and Erythema Nodosum

DR. ISADORE PILOT, Chicago. Erythema nodosum was observed as a sequela of streptococcal sore throat in which filtrates of the hemolytic streptococci produced typical nodules on intradermal injection. Tuberculin tests in two patients gave no reaction. In another rare type of case, erythema nodosum complicated lymphogranuloma inguinale. The Frei test was positive, and the lesion from the intradermal test was markedly nodular. A third common type gave a nodular reaction to tuberculin. In the two latter instances, streptococcus filtrate caused no reaction. It would appear that erythema nodosum is not a clinical entity but a peculiar hypersensitive response of the skin to toxic products from foci of infection due to streptococci, tubercle bacilli, the virus of lymphogranuloma inguinale and perhaps other agents.

DISCUSSION

DR. H. M. CONNER, Rochester, Minn. I should like to ask Dr. Pilot whether he considers these reactions sufficiently definite, so that, given a case of erythema nodosum, one could, by use of a series of antigens, decide on the etiologic agent.

DR. ISADORE PILOT, Chicago. These reactions were not of the immediate allergic type that one sees with proteins. They come on in twenty-four hours and instead of fading, as in connection with the tuberculin test, they go through an involution as an erythema nodosum nodule and persist up to ten days. I have tried other streptococcus antigens, for instance the scarlet fever streptococcus. This will give an inflammatory reaction but the nodule is not as violent or as marked in its extent as the nodule from the autogenous strain. As far as treatment is concerned there is nothing to do in these cases. When the streptococci disappear from the throat, the focus apparently is of only transitory nature and the erythema nodosum disappears. In one instance although the erythema nodosum cleared up the arthritic pains persisted. About four months later the tonsils were removed and the same streptococci isolated. The arthritic pain that had been present disappeared, so the tonsils could be considered the focus. In using tuberculin, one should employ 1:10,000 instead of 1:1,000. With reference to streptococcus antigens, one can obtain some definite reaction with stock antigens of hemolytic or even non-hemolytic type but it is preferable to make the antigen from the patient's own throat if there is a definite history of definite evidence of a focus.

Measurements of Muscular Work in Occlusive Arterial Disease of the Lower Extremities

DRS. DWIGHT L. WILBUR and GEORGE E. BROWN, Rochester, Minn. An attempt has been made to develop an apparatus with which the movement of walking is simulated in order that measurements of muscular work may be made on the basis of horse power units. In this way the extent of incapacity of patients with occlusive arterial disease and intermittent claudication and the effects of therapy on them can be determined. The apparatus consists of a sewing machine modified so that the patient's leg must push against a weight which may be adjusted by noting the duration of the experiment, the horse power that is developed can be measured. By this method the muscular capacity of the leg of twenty-nine normal persons who served as controls and those of thirty patients with various types of peripheral arterial disease has been measured. The method is of value and with modification, which come with experience, should be an adjunct in the study and treatment of patients with localized forms of arterial disease. Errors inherent in this type of test are of three kinds:

personal threshold of pain and fatigue, the factor of muscle conditioning, and unknown influences of the general state of the patient. Fairly close approximations of the amounts of muscular work can be obtained on repeated tests under variable conditions in normal and diseased subjects. The following results have been obtained: 1. As a group, those with occlusive arterial disease (thromboangiitis and arteriosclerosis obliterans) of the lower extremities are unable to perform as much work with their legs as do normal persons and the degree of disability is quite similar in the two types of arterial disease. It follows, therefore, that the disability is dependent on occlusion rather than on the type of disease underlying the occlusive process. 2. In the normal and diseased subjects as groups the time of onset of the sensation of fatigue in the calf muscles was very much the same, but the duration of the exercise was sharply different. 3. No correlation could be established between the amount of muscular work performed and the severity of arterial occlusion of an extremity as demonstrated by the presence of pulsations of the arteries of the extremity and the grade of vasospasm as measured by dilatation with fever. 4. In those cases in which intermittent claudication was reproduced, the duration of the exercise, the total amount of work performed, the time of onset of fatigue, and the pulsation of the arteries were significantly less when compared with the group in which occlusive arterial disease was present but in which intermittent claudication was not a distinct symptom.

DISCUSSION

DR. L. N. KATZ, Chicago. In a series of studies carried out in the laboratory, my associates and I have been able to show that there are a number of factors contributing to the production of pain in intermittent claudication, the most important factors being the amount of muscular work, circulatory stasis, and the available oxygen to the tissues. I should like to ask the authors whether the patients had a preliminary period of rest before performing the exercise. We have found quite consistently, and contrary to the previous observations of Lewis, that a period of ischemia preceding the exercise will materially shorten the amount of exercise necessary to produce pain. I should also like to ask whether an attempt was made to evaluate the role of circulatory disturbances in venous flow, particularly those due to varicosities. We have found that venous stasis alone, without arterial occlusion, may lead to the development of pain on exercising the limb. Finally, I should like to ask whether an attempt was made to check the rate at which the exercise was performed by the patients. It has been clearly established that a given quantity of work may require a different amount of muscular effort, depending on the rate at which the movements are performed.

DR. DWIGHT L. WILBUR, Rochester, Minn. Most of our patients were rested for a period of from ten to fifteen minutes preceding the test. It did not seem probable that moderate exercise just preceding the test had any great influence on the results of the exercise. Venous stasis was not present to a recognizable degree in the majority of our patients. Varicosities were uncommon. We considered the rate at which the machine was run and found it to be significant in regard to the horsepower developed but not as regards the total amount of work done. As a group, the arteriosclerotic individuals ran the machine considerably faster than did normal individuals and patients with thromboangiitis obliterans.

Relationship Between Acid-Base Equilibrium and Bacterial Flora of the Stomach

FLOYD ARNOLD and MARION HOOD, Chicago. There are certain differences between the behavior of bacteria in contact with living cells and their behavior in test tube. A study of *in vivo* bacteriology has opened up new fields. Several body surfaces have been studied, such as the skin, the oral and nasal cavities, the conjunctiva, the stomach, the small intestine, and the vagina. Some observations dealing with the stomach are to be reported here. Arnold and Johnson found that the free acid gastric contents of dogs did not kill bacteria but exercised only a bacteriostatic influence on the flora. Continuous observation showed bacteria to be nonviable in the gastric lumen in the presence of free acid but a heavy viable flora appeared at 1 minute the free acid disappeared or was neutralized.

Arnold recorded certain bactericidal or self-disinfecting powers of the small intestine. There is a correlation between the bacterial flora of the stomach and the small intestine. Gastric studies were extended to human subjects. Cultures of fractional aspirations of fasting gastric contents were taken on plain agar plates and the hydrogen ion concentration was determined colorimetrically. The acid-base equilibrium was adjusted toward the acid as well as the alkaline ranges and the changes in endogenous bacterial flora were determined by agar cultures as well as direct smears. Hydrochloric, acetic and lactic acid solutions and lemon and orange juice were used as acidifying agents. There are definite correlations between the acid-base balance and viable bacteria in the gastric lumen. The experimental work reported on laboratory animals has been substantiated. Dr. Gulbrandsen from this laboratory has found a correlation between the acid-base balance of the duodenum and the bacterial flora of this region. Acid-reacting duodenal contents are usually sterile on culture, alkaline-reacting duodenal contents give heavy growths of bacteria by cultural methods. The development of knowledge of the bacterial flora residing within the lumen of the stomach and upper levels of the small intestine may indicate a new approach to certain metabolic disturbances associated with decreased gastric acid secretions. The possible influences of this intragastric bacteriostatic mechanism on the degenerative diseases of the older age groups has been outlined by Arnold.

Effect of Splanchnic Nerve Section on Carbohydrate Metabolism

DRS G. K. FENN and GEZA DE TAKATS, Chicago. An attempt has been made to stabilize the carbohydrate tolerance and to reduce materially the insulin requirement in the juvenile diabetic patient. This end has been sought by means of section of the splanchnic nerves. One case (already reported) in which a rather striking result was achieved was in contrast to a second case, in which the result was much less striking. A method of case selection has been devised which may result in the separation of diabetic patients into different groups. The use of insulin sensitivity curves in normal persons and diabetic patients and the blood sugar responses to the ingestion of galactose before and after the administration of ergotamine constitutes a method of case separation that appears to be of value in the selection of cases for this type of treatment.

DISCUSSION

DR RUSSELL M. WILDER, Rochester, Minn. I regard these studies as of great importance. They bear on the heretofore ambiguous subject of sensitivity to insulin. But I am inclined to dispute the conclusion that different varieties of diabetes are indicated by these different reactivities to injections of insulin. I suspect rather that the test is a test of different kinds of people with the same disease and that the response obtained depends on the irritability of the nervous system.

DR R. W. SCOTT, Cleveland. I should like to ask whether the authors made any observation on how these individuals tolerate the effect of gravity on the circulation.

DR M. H. NATHANSON, Minneapolis. I am interested in the result obtained with ergotamine. The specific action of ergotamine is paralysis of the sympathetic nerve endings. In some studies which I am carrying out I attempted to modify the effect of epinephrine on the cardiac mechanism with ergotamine. I found, however, that I could not give doses sufficiently large in human beings to paralyze the effect of epinephrine on the heart. When one inspects the pharmacologic literature one finds that the doses of ergotamine used to antagonize the pressor effect of epinephrine in the experimental animal are much larger than those which are used in man. It is interesting, therefore, to see that there is some modification of sensitivity to insulin in man with moderate doses of ergotamine.

DR E. L. SEYRINGHAUS, Madison, Wis. It is rather noticeable that among juvenile diabetic patients there are occasionally young men and young women that are difficult to manage over a long period because of sudden shifts in glycemia. Erratic hyperglycemia properly leads these patients to

increased doses of insulin. Hypoglycemic reactions of severe types frequently follow. These patients seem to be emotionally unstable also. I wonder whether the authors have any data as to whether these patients that are more easily stabilized after splanchnic section are among those who are emotionally unstable, also whether they have any observations on change in the sympathetic mechanism after splanchnic section and whether it has any effect other than on the carbohydrate metabolism such as on the responses to emotional stimuli.

DR GEZA DE TAKATS, Chicago. It is obviously more difficult to suppress the pressor effect of epinephrine with ergot than the hyperglycemic effect. It is also true, of course, that much smaller quantities of epinephrine are necessary to produce hyperglycemia than to produce the rise in the blood pressure. The flattening of the hyperglycemia curve after the administration of ergotamine may be an inhibition of the sympathico-suprarenal mechanism, but it also may be due to an increased utilization of sugar in the periphery. Our present data do not supply any information on this question. In reply to Dr. Seyringhaus I may state that the splanchnic section did stabilize tolerance in the first case, in which two respiratory infections were not followed by decrease in tolerance. In the second case we had no such experience. In regard to Dr. Scott's question, the effect of gravity on blood pressure following splanchnic section was quite marked for about four weeks after both operations. The systolic pressure dropped from 100 to 85 and as low as 75 mm. of mercury after three or four minutes of erect posture. However, after from four to six weeks neither of the two patients showed this postural hypotonia. Regarding Dr. Wilder's question, it may be noted that the types of diabetes are different but that the same type showed different manifestations in different types of constitutions. Nevertheless, an increased sympathetic irritability of the glycoscretory mechanism may be beneficially affected by the suppression of such nervous impulses. The operation as we see it now, seems worthy of trial in juvenile diabetic patients who are insulin resistant and respond well to ergot.

Special Features of the Epidemic of Encephalitis in the St. Louis Area

DRS G. O. BROWN, R. O. MUEHLER, MAURICE W. SBER-TOLI and A. F. DEL VALLE, St. Louis. The average case was characterized by sudden onset with headache, muscular aches and sometimes chills, and by high irregular fever usually of seven to fourteen days' duration terminating by lysis. Meningeal symptoms such as headache, drowsiness, stupor, mental confusion and delirium predominated. Cranial nerve palsies were relatively rare. Neck rigidity, muscular tremors and spasticity, positive toe signs, absent or unequal tendon, abdominal and cremasteric reflexes were the most common physical observations. Some evidences of myocardial weakness were often noted in severe cases. Respiratory symptoms other than terminal pneumonia rarely occurred. Nausea and vomiting were frequent. The urine occasionally contained albumin, pus, erythrocytes and casts. Some elevation of blood nonprotein nitrogen was not infrequent. Blood sugar tended to be slightly increased, but glycosuria was very rare. Moderate polymorphonuclear leukocytosis was present in the majority of cases. The spinal fluid was clear, with usually some increase in pressure, a positive globulin, a normal sugar content, and an increased count of lymphocytic cells. The colloidal gold showed a tabetic curve. Convalescence was usually rapid, with few immediate serious nervous sequelae. The mortality was low in patients under 40 years of age. It was especially high in cases showing preexisting morbid conditions particularly hypertensive vascular disease.

Pathologic Changes in Patients Dying of Encephalitis

DRS R. S. MCKENFUS and H. A. MCCORDOCK, St. Louis. The most interesting pathologic lesions characteristic of the various types of encephalitis and the lesions found post mortem in patients dying in the present epidemic were found in the kidneys which were swollen and intensely congested, the pelvis being studded with small hemorrhages. Intramuscular inclusion bodies were found in the cells of the tubules by Dr. Margaret Smith in about 50 per cent of the cases so far studied.

DISCUSSION ON ENCEPHALITIS

DR M A BLANKENHORN, Cleveland I should like to ask whether the pulmonary changes and kidney lesions can be considered in any way complications or are they secondary infections?

DR H M CONNER, Rochester, Minn Has there been any attempt at the production of the disease in animals and if so, with what success? Also, I should like to ask whether or not the inclusion bodies in the kidneys have any significance

DR C F KEMPF, Indianapolis I had an opportunity of seeing cases in Indianapolis during the epidemic of encephalitis that appeared in 1929, 1930 and 1931 Clinically this group of cases, of which there were something like 260, is very similar to the clinical picture described by Dr Broun and his associates I doubt whether from the clinical observations one could tell the difference There were a few mild cases, but the greater proportion terminated fatally in a very short time There were more signs of meningeal irritation, and a greater number of these cases showed delirium In the spinal fluid more cases presented a low cell count than an increased count The colloidal gold changes were rather similar However intraspinal drainage was continued in many of these cases for several weeks The greatest difference in the two epidemics was in the pathology The cases seen in Indianapolis either showed nothing more than a dilatation of the blood vessels, with some damage to the cortical cells, or some very definite meningeal changes without any perivascular areas or very few areas of focal necrosis The virus was not demonstrated Certainly the conditions clinically are very similar

DR G O BROUN, St Louis The clinical picture presented was not sufficiently specific in itself to permit of absolute diagnosis In the group that we studied there were a number of cases originally diagnosed as encephalitis that did not show it I will mention one case specifically The history and physical observations, if compared with those in many cases of encephalitis, were practically identical There were headache, fever, nausea, vomiting, somnolence, slight rigidity of the neck, inequity of the reflexes, and one or two positive toe signs The spinal fluid was clear, with a cell count of 52, and normal spinal fluid sugar It proved to be a case of typhoid Another patient came in with headache, neck rigidity and a spinal fluid cell count of 30 Very quickly after admission the patient was found to be suffering from malaria and on the administration of quinine the symptoms cleared up I think it must be remembered that there is probably some increase in the spinal fluid cell count in many acute febrile diseases as well as in encephalitis This means that every case must have a bacteriologic study before the diagnosis can be established with certainty Regarding the colloidal gold curve, we usually made two spinal fluid examinations, one at the time of admission and one at the time of discharge Ninety per cent of the colloidal gold tests showed a tabetic curve on admission and most of them showed the same on discharge If there is any change it usually is a flattening out of the curve We had one or two with a parietic curve and a few more with a normal curve The cell count was still somewhat high in convalescents, many cases showing counts of from 10 to 30

DR R S MCKENFESS, St Louis I am not able to say definitely whether the changes in the lungs and in the kidneys were actually part of the disease picture or were complications They undoubtedly occurred in quite a high percentage of the cases It is probable that they were in some way associated with the disease but we have no direct proof of this As to the inoculation of animals numerous attempts were made from the onset of the epidemic to determine the etiologic agent Routine blood cultures and spinal fluid cultures were made Because of the difficulty in some cases in distinguishing it clinically from typhoid many stool cultures were made With a few exceptions these were negative When positive cultures were obtained the variety and purity of organisms were such that we felt that we were dealing with contaminant On the animals inoculated manifestations similar to disease seen in man were observed in our laboratory in monkeys The monkeys showed an elevation of temperature associated with some incoordination and tremors The disease was passed from monkey to monkey with some difficulty During this time we

were sending autopsy material to a number of different laboratories The material sent to Dr Webster at the Rockefeller Institute was used in a strain of mice highly susceptible to neurotropic viruses He was able to produce a disease that could be maintained in these animals Accordingly, mice were inoculated from second passage monkeys and a disease similar to that seen by Dr Webster was established in stock mice The identity of this virus has not been settled but studies are in progress We are exchanging strains of virus with Dr Webster and these will be compared in both laboratories

The Electrocardiogram in Myocardial Infarctions A Review of 107 Clinical Cases and 108 Cases Proved at Necropsy

DR A R BARNES, Rochester, Minn This study had three primary objects in view 1 To furnish an answer to the question of whether or not other cardiac lesions produce electrocardiographic changes which duplicate the characteristic electrocardiographic picture of acute coronary occlusion 2 To reexamine the value of the RS-T changes in the electrocardiogram following acute myocardial infarction as a means of predicting the situation of infarction before death 3 To determine, in those cases in which electrocardiographic evidence of acute myocardial infarction is lacking, the reasons for this failure Study of cases encountered at the Mayo Clinic leads to the following conclusions 1 No other cardiac lesion reproduces in its entirety the typical RS-T modifications of the electrocardiogram described as characteristic of acute myocardial infarction 2 In no instance in which a typical T_1 or T_2 type of electrocardiographic change has developed have we failed to find myocardial infarction in the region anticipated Failure to do so has meant either that the tracing was not typical or that sufficient study of the pathologic change in the predicted region of infarction has not been carried out 3 A considerable number of infarctions are not signalized by the development of typical changes in the RS-T segment of the electrocardiogram In our cases this failure was accounted for by one of the following causes (a) Electrocardiograms were not obtained in sufficient number or in proper time relation to acute myocardial infarction (b) There were multiple areas of acute myocardial infarction (c) The presence of bundle-branch block obscured the electrocardiographic pattern of infarction (d) Pericarditis or pericardial effusion modified the electrocardiographic changes (e) The amplitude of the deflections in lead I or lead II was so small that the RS-T changes characteristic of infarction could not be recognized (f) The tracing was obtained when a patient was dying

The combined consideration of the RS-T and Q patterns yield more information regarding the presence of myocardial infarction than does the consideration of either pattern alone Frequently the two patterns are equally indicative of infarction Fairly commonly the RS-T segment changes are more typical of myocardial infarction than are the Q patterns In a smaller number of patients the Q patterns are more typical of infarction than are the RS-T changes There is a considerable group of patients in whom the RS-T changes indicate myocardial infarction when the Q patterns are entirely lacking There is an occasional case in which the Q pattern is indicative of infarction when RS-T changes are absent

In our cases the Q_1 type of electrocardiogram is found in association with infarction involving the apex and anterior portion of the left ventricle The Q_2 type of electrocardiographic change is associated with infarction of the basal portion of the left ventricle

The development of a highly characteristic T_1 or T_2 type of electrocardiographic change following acute coronary occlusion seems to indicate a better prognosis than does an atypical tracing Typical T_1 or T_2 electrocardiograms were encountered six times as commonly as atypical electrocardiograms in the patients who recovered In patients who died atypical tracings predominated over typical tracings in a ratio of four to three The atypical tracings usually were found to be associated with multiple infarctions, extensive single infarctions, or complicating pericarditis, any one of which obviously increases the gravity of the outlook

In case the reports of which have been published as well as in our cases T_1 and T_2 types occur with about equal frequency

This means that the posterior basal portion of the left ventricle is infarcted approximately as often as the anterior apical portion.

Effect of Theophylline Ethylenediamine on Cardiac Infarction Produced by Ligation of the Coronary Arteries in the Dog

DRS W M FOWLER, H M HUERVITZ and FRED M SMITH, Iowa City. In perfusion experiments on the isolated rabbit heart, theophylline ethylenediamine produced a far greater and more consistent increase in the rate of coronary flow than any other of the drugs that were studied. The action of theophylline ethylenediamine on the coronary circulation was further investigated through its effect on the size of the infarct produced by the ligation of a coronary artery in the dog. In the dogs receiving theophylline ethylenediamine there was a decided reduction in the size of the infarct as compared to that of the control series. Moreover the infarct was more sharply demarcated and did not present the usual frayed out appearance encountered in the untreated animals. These results indicate that this drug promotes the development of collateral circulation and thereby reduces the extent of the myocardial damage resulting from the ligation of a coronary vessel.

Cardiac Infarction Its Subjective Symptoms in Relation to Its Pathologic Anatomy

DR NATHAN S DAVIS III, Chicago. There have been suggestions that the presence or absence of pain in cardiac infarction is related to the underlying pathologic anatomy. In an attempt to confirm or refute this theory, some seventy-five records from the Department of Pathology of Northwestern University Medical School have been studied. It appears that the pain of cardiac infarction like that of angina of effort is due to relative ischemia of the myocardium more than to anything else, that complete ischemia of a limited area of the myocardium does not cause pain.

DISCUSSION ON HEART DISEASE

DR L N KATZ, Chicago. In regard to Dr Barnes's paper a careful survey of the reported autopsy cases by Gilchrist and Ritchie failed to show any clear-cut correlation between the configuration of the electrocardiogram and the location of the infarct. This conclusion Wilson and his co-workers also arrived at from a survey of their autopsy cases. At Michael Reese Hospital, Drs Hamburger, Priest, Saphir and I have examined thirty-four consecutive autopsy cases in twenty-one of which electrocardiographic records were taken. We could not consistently locate the position of the infarcts in this series from the appearance of the electrocardiograms. Korey and I have recently injected alcohol into various regions of the dog's heart and found that the electrocardiographic changes produced are not related to the location of the injured area. Furthermore, it must be borne in mind that as Dr Bohning and I have recently shown, it is not always easy to fit the electrocardiogram into the T_1 or T_2 types. In regard to Dr Davis's paper, in the study mentioned we could not correlate between angina pectoris and the nature of the infarct.

DR WARREN B COOKSEY, Detroit. For several years I have been interested in a group of cases in which small infarcts were suspected but in which the infarcts could not be proved clinically. During a study of serial electrocardiograms following coronary thrombosis I was impressed by the occasional striking changes that occurred in both T_1 and T_2 . In certain cases the T_1 became very sharp of greater than normal amplitude and positively directed whereas T_2 became deeply concave negative. Because of the striking character of these changes, I have been interested in the frequency with which they also occur in patients of coronary sclerotic age with suggestive symptoms but who have never had a gross infarction. I have followed sixty cases with but one autopsy to date. This patient was being operated on under gas when, because of deep cyanosis he developed ventricular fibrillation and died. He had numerous small healed infarcts along the course of the left descending coronary. I should like very much to hear whether Dr Barnes or Dr Scott or Dr Katz has encountered these changes.

DR ROY W SCOTT, Cleveland. These three papers present many aspects for discussion to those interested in heart disease.

The paper of Dr Fowler and his associates on the effect of theophylline ethylenediamine on the dog's coronary arteries raises the question as to how closely these results apply to man. It has been known for a long time that caffeine and its derivatives increase the coronary flow in the animal heart, but few carefully controlled observations have been made on man. The best of these, so far as I know, are the studies recently reported by Wayne and Laplace, who found that theophylline ethylenediamine, either by mouth or intravenously, increases the amount of exercise tolerated by patients with angina of effort. The clinical reputation of theophylline ethylenediamine as a coronary dilator is based largely on statements that its use over long periods diminishes the frequency and severity of the attacks. Such evidence is admittedly difficult to evaluate. Dr Fowler and his associates mentioned that their animals receiving theophylline ethylenediamine for twenty-one days following coronary ligation showed smaller areas of infarction than did animals that did not receive the drug, and they ascribe their results solely to the effects of the drug. This conclusion would seem warranted were there not a considerable variation in the coronary circuit in normal dogs. Dr Davis's paper illustrates the difficulties in correlating a clinical syndrome with anatomic observations. Proved cases of acute coronary thrombosis occur without pain. Recently I saw a patient with excruciating pain in the left elbow but not in the chest. One is reminded of a small group of individuals dying of myocardial insufficiency from coronary disease in whom chest pain may never be a conspicuous feature. I refer to those cases in which the coronary arteries appear to be slowly occluded, resulting in an extensive fibrosis of the ventricles.

DR M H NATHANSON, Minneapolis. I have had an opportunity to observe under somewhat controlled conditions the possible effects of theobromine and theophylline compounds in clinical cases. These compounds are expensive and at our hospital it was found that the cost approximated \$400 a month, owing to the freedom with which the interns and residents prescribed these substances. Several months ago it was decided that these compounds could be prescribed by only two members of the staff. In the outpatient department it was found that while many patients did as well when sodium nitrite was substituted, certain other patients returned and stated that there was a definite increase in the frequency of their anginal attacks when the theobromine compounds were discontinued.

DR A R BARNES, Rochester, Minn. I regret that time does not permit me to answer each of Dr Katz's criticisms in detail. Detailed analysis of the cases reported by Gilchrist and Ritchie shows that such inconsistencies as they have called attention to can be explained on the basis of the facts that I listed in discussing the cases of acute myocardial infarction in which electrocardiographic evidence of that event was lacking. For the most part, Wilson and his co-workers corroborated our localization hypothesis. In the last issue of the British journal *Heart*, Dr Wilson thought he had found a definite exception to this localization in a patient with a T_2 type of electrocardiogram. Subsequent careful pathologic study proved this not to be the case. Dr Katz maintains that infarction in the anterior and in the posterior portion of the left ventricle of the dog gives an identical tracing. A review of the experimental work on the dog's heart does not support that contention. I should like to point out that it is important for all physicians to consider both the Q and T patterns in an attempt to diagnose acute myocardial infarction. There is no doubt in my mind that typical T_1 and T_2 patterns will localize myocardial infarction accurately, but the confirmation of that must be left to the future. I am confident that, in time, an agreement will be reached.

DR NATHAN S DAVIS III, Chicago. In replying to Dr Katz's question I would say that in some of these cases there was hemorrhagic infarction and no pain. In the series there were several cases in which no narrowing of more than one branch of the coronary artery is reported. There may be some sclerosis in other branches, but no narrowing was reported in the record. I might also state that in classifying these cases I considered those with pain and those without pain. Some patients had pain only in the arm and shoulder, others only epigastric pain. A history of that sort of pain was considered positive in making this classification.

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers to THE JOURNAL in continental United States and Canada for a period of three days. Periodicals are available from 1925 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending, but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Guanidine Intoxication Complicating Factor in Certain Clinical Conditions in Children A S Minot and Katharine Dodd Nashville Tenn—p 522

Encephalitis and Measles—Peterman and Fox studied thirteen cases of encephalitis complicating measles. The cases conform to the typical picture as reported in that in twelve the onset occurred between two and six days after the onset of the rash and in one in eight days. In all but one the encephalitis began with stupor or drowsiness, and in this case the onset was characterized by restlessness and convulsions. Eleven patients (two were not so examined) exhibited a polymorphonuclear leukocytosis ranging from 12,600 to 26,000 leukocytes per cubic millimeter even up to fifteen days after the onset. The percentage of polymorphonuclears ranged from 74 to 84. All fluids were clear and seven were under increased pressure. The cell count ranged from 5 to 380, of which from 40 to 98 per cent were lymphocytes. The globulin was positive in six of the eleven fluids so tested. The sugar ranged from 71 to 125 mg per hundred cubic centimeters in the eight fluids so tested. The colloidal gold test was made on six fluids, in three it was negative and in three positive. The authors propose three theories in the explanation of encephalitis complicating measles: (1) It is the result of a virus independent of measles, (2) it is an allergic or anaphylactic phenomenon or (3) it is a virus activated by the measles organism. On the basis of the remarkable consistency in the clinical picture and observations in most established cases of encephalitis complicating measles, viz, time of onset in relation to the rash, the fever, the drowsiness or convulsions, the polymorphonuclear leukocytosis, the pleocytosis and the increased sugar in the spinal fluid and the pathologic changes the authors are inclined to believe that the condition is a clinical entity produced by some specific virus or organism.

Acute Pyothorax—Bloch and Parrish treated by aspiration and air replacement fourteen infants and children having acute pyothorax following pneumonia. The apparatus consists of a 50 cc Luer syringe and a large needle. Fairly certain location of the empyema should be made clinically and roentgenologically. The left thumb is pressed against the lower border of the upper rib thus protecting the intercostal artery vein and nerve. The needle is inserted through the intercostal space directly beneath the thumb. By the aspiration of pus it is definitely ascertained that the needle is in the empyemic cavity. A syringe of pus is then removed and an equal amount of air is injected with the same syringe. This is repeated until on aspiration no pus enters the barrel. The injection of an additional 10 or 15 cc of air will facilitate the aspiration of any remaining pus. Tappings are repeated every four to seven days.

Guanidine Intoxication—The procedure that Minot and Dodd used for the determination of guanidine is described.

the earlier method described by Major and Weber with a few minor changes. The estimation was carried out on protein-free filtrates prepared from blood by the method of Folin and Wu. This filtrate contains the interfering salts and nonprotein extractives of blood and the guanidine in far too great dilution for colorimetric estimation. Before the color test is made, most of the salts are removed, creatine is converted to creatinine and the guanidine concentrated in a small volume of solution. In the authors' experience the highest concentrations of guanidine occurred in patients presenting rapid loss of fluid in diarrhea or having extensive necrosis in burns or acute injury of the liver or in certain types of overwhelming infection. Apparently hyperguanidemia is a result of secondary factors rather than an essential feature of any particular disease. The intoxications seen clinically are in many respects similar to intoxication produced by experimental guanidine poisoning and are relieved by calcium therapy. The authors believe that calcium medication is a valuable supplement to the common therapeutic measures employed in the management of such toxemias.

Diagnostic Test for Infectious Mononucleosis—Bunnell employed the sheep cell agglutinin test in more than 2,000 cases representing seventy six clinical conditions. With the exception of serum disease, he has been unable to demonstrate an appreciable increase of heterophil agglutinins for sheep cells in the serums above the normal dilution of 1/8. In fifteen cases of infectious mononucleosis he observed a consistent increase in all cases. The titers ranging from 1/64 to 1/4,096, apparently depended to a considerable extent on the stage of the disease at which the serum was obtained and on the severity of the illness. None of the common conditions manifesting a similar clinical picture such as acute adenitis, tuberculous or syphilitic adenitis, Hodgkins disease, acute or chronic lymphatic or myelogenous leukemia, aplastic anemia, hemorrhagic purpura, agranulocytic angina or Vincent's angina have shown an increase in heterophil agglutinin titer. Cases presenting a suggestive clinical and blood picture whose blood serum shows an agglutination for sheep cells in a dilution of at least 1/64 can apparently safely be diagnosed as infectious mononucleosis and a favorable prognosis given.

Nonprotein Nitrogen and Acute Coronary Occlusion—Steinberg emphasizes the function of the kidney in coronary occlusion. A certain procedure is needed in the arterial system

for the kidney to carry on its normal function. His observations in acute coronary occlusion do not coincide with the thought that in essential hypertension the elevated blood pressure is a safety mechanism so that the vital renal function may be performed. He presents sixteen cases in two of which the drop in blood pressure and a definite and marked diminution in urinary output are not sufficient in themselves to account for the nonprotein nitrogen factor in acute coronary occlusion, for, although both had a decided and marked drop in blood pressure and a diminution in urinary output the nonprotein nitrogen did not become markedly elevated. His study of the retention of nonprotein nitrogen in the blood plasma in the sixteen cases of coronary occlusion indicates that nine showed a nonprotein nitrogen retention that was above 40 mg per hundred cubic centimeters (one had 40 mg). Of the six fatal cases, only one showed a nonprotein nitrogen below 40, and three showed progression or retention of waste products in the blood stream or continued elevation without necessarily progression in the amount of nonprotein nitrogen. Three patients in whom serial nonprotein nitrogen studies were made and who showed a definite tendency toward lowering of the nonprotein nitrogen value recovered. None of the cases examined post mortem showed evidence of any marked nephritis.

Typhoid Vaccine in Treatment of Chorea—Capper and Bauer treated twenty-three cases of chorea, nine of which were chronic, by means of typhoid-paratyphoid vaccine intravenously. Nineteen were entirely symptom free at the time of discharge from the hospital. Of the nine chronic cases in which the average duration of the symptoms was four and one half years, one showed a persistent talkativeness and one a persistent blinking of the eyes, but all other symptoms had disappeared. One patient who suffered from chorea for two months was improved following the vaccine injections, but the authors were unable to continue their observations because of a transfer to another hospital soon after the injections were completed. Only one of the twenty-three cases, a subchronic one, was definitely refractory and the twitchings and irregular movements persisted in spite of the treatment. Nevertheless when the patient returned three months later for follow-up examination, he was entirely well. A reexamination of eleven cases, from three to fifteen months subsequent to discharge, showed seven and possibly eight to be entirely well, in spite of the fact that over 50 per cent of them belonged to the class of chronic chorea. No untoward effects were noticed in any of the patients from the vaccine injections. The authors' method consisted in injecting intravenously a mixture of typhoid paratyphoid A and paratyphoid B vaccine each cubic centimeter containing 500,000,000 of typhoid and 250,000,000 each of paratyphoid A and B organisms. The initial dose was from 0.15 to 0.2 cc. When the patient did not react to the initial dose or to an increase of 0.1 cc daily the increase in dosage was made more rapidly. The injections were continued daily usually for six or seven days, when a rest period of several days was instituted. If the child did not recover completely after the first series of six or seven injections, a second, third or even fourth series of injections was instituted.

Menstrual Disturbances Due to Achlorhydric Anemia—Haden and Singleton studied the menstrual disturbances in twenty-nine cases of simple achlorhydric anemia. Abnormalities of menstruation are found commonly in this disease and constitute one of its most characteristic features. Achlorhydria with idiopathic hypochromic anemia is pathognomonic of the disease. The disease probably belongs in the deficiency group and responds well to the administration of adequate doses of iron. Simple achlorhydric anemia should be suspected in all cases of unexplained menstrual disturbances and the suspicion verified or excluded by gastric analysis and careful blood examination. In the authors' series the menstrual disturbances occurred almost as frequently as symptoms due directly to the low hemoglobin content of the blood.

Loss of Weight in the New-Born—Kugelmass and his associates point out that the initial loss in weight in the new born can be prevented by the oral administration of a solution consisting of 6 per cent gelatin (pH 6.2) 3 per cent dextrose and 0.5 per cent sodium chloride at intervals of two hours throughout the twenty-four-hour cycle immediately after birth. The characteristic clinical picture of the new-born is a result of birth shock and is more effectively combated by a hydrating solution than by milk mixtures during the first two or three days of life. The total fluid intake of the new born properly conditioned to both the breast and the bottle was as much as twice that of the series receiving the routine nursery care. Preventing the loss of weight in the new born produces rapid disappearance of the so called physiologic apathy, somnolence and stupor secondary to birth shock and the compensated acidosis universally present. The new born infant shows a hypoglycemia during the first days of life and a sugar tolerance curve of low peak thus indicating a dire need for carbohydrate as well as a tendency to utilize store and exhaust their endogenous supply of carbohydrate more rapidly than older children. Determinations of the refractive index and viscosity of the serum of the new born revealed the concentration of the blood on the first days of life, gradually attaining normal values following administration of food in the control series but the new-born treated with the hydrating solution showed a markedly constant course for both refractive and viscosimetric curves. The gelatin component of the hydrating solution decreased the clotting time to less than three minutes in comparison with seven minutes in the control series.

Premedication Agent in Surgery—Axelrod studied the advantages of allyl-isopropyl-barbituric acid (alurate) in 150 surgical cases. He found the barbiturate to have definite clinical

cal advantages as previously suggested by animal experimentation. The oral administration of the substance, in tablet or capsule form, is a satisfactory method. The optimal dose appears to be 10 mg per kilogram of body weight (i.e., approximately 1 grain [0.065 Gm] for every 15 pounds of body weight, excessive fat, as in obese patients, being discounted). Using a divided dosage is rational and satisfactory. Side actions occur less often than have been reported from large single doses of other barbiturates. The volume of the anesthetic can be appreciably reduced. There does not seem to be any marked delay in the occurrence of the postoperative reaction. The need for postoperative nursing care not only is not increased, as reported for some barbiturates, but is diminished in most cases.

Injection of Pudendal Nerve.—O'Hearn and Knauer used the following technique in seventy-six private and twenty-four ward patients. With the patient in the gynecologic position the inner margin of the tuberosity of the ischium is located and, at a point on a line with the anus but close to the ischium the tip of the needle is inserted in the direction of the spine of the ischium, which is palpated through the vagina or rectum. The tip of the needle when inserted about 5 cm encounters the resistance of the perineal fascia, beyond which there seems to be an open cavity. The pudendal nerve leaves the pelvis through the greater sacrosacral foramen, circles the spine of the ischium and reenters the pelvis through the lesser foramen. Therefore, by palpating the spine with the fingers of one hand and using it as a guide, it is possible to inject the solution at the proximal edge of the spine and cause complete anesthetization of the pudendal nerve and the structures which it supplies. Ten cc of a 1:500 solution of pantocain is injected into this region. The needle is withdrawn until its tip is free from the perineal fascia and then is redirected upward and outward onto the face of the tuberosity of the ischium, when the remaining 3 to 5 cc of the solution is injected. This solution is massaged upward over the surface of the tuberosity, through the potential space existing between the gluteus maximus muscle and the tendinous insertions of the extensor group of muscles, thereby anesthetizing the perineal branches of the small sciatic nerve which are constantly present in this space. A complete anesthesia to the sense of pain was manifested in all the structures composing the floor of the perineum, including the lower third of the vagina and the posterior half of the labia majora, and the perineum may be "ironed out" painlessly as well as sutured. The time of injection is not until the head is on the perineum and the membranes are ruptured and every assurance is offered that the continuance of labor will not exceed four and a half hours, which is the average duration of this anesthetic with 1 cc of 1:1,000 epinephrine added. Its effect, without epinephrine continues for two hours.

Variations of Intragastric Temperature.—Thiessen and Still studied the variation of intragastric temperatures of

patients suffering from ulcers of the gastro-intestinal tract in relation to vasodilating drugs and test meals. After stimulation with histamine, the mean rise in oral temperature was 0.25 C, and the mean rise in rectal temperature was 0.19 C. The mean fall in intragastric temperature was 0.18 C initially, and then it made a rise above the initial temperature comparable to the rise noted in rectal and oral readings. After acetylcholine the intragastric temperature rose on an average 0.16 C, as compared to a rise of 0.08 C for the rectal temperatures and insignificant variations in oral temperatures, it made a sharp rise at the two hour reading. A peripheral and visceral dissociation was not so marked after the administration of acetylcholine as when histamine was used. After the administration of alcohol, the rectal and oral temperatures rose gradually. After an initial drop, the mean rise of intragastric temperature was 0.4 C, then the temperature dropped to normal. A definite splanchnoperipheral dissociation was apparent in 60 per cent of the experiments. The dissociation of visceral from peripheral reactions affecting the temperature was most apparent after the administration of histamine, less so but fairly definite after alcohol, and variable after acetylcholine. In the presence of artificially produced fever the maximal mean rise of oral temperature was 0.56 C, of the rectal temperature 0.59 C, and of the intragastric temperature 1 C. In only 20 per cent of the cases was a definite splanchnoperipheral dissociation seen, although this phenomenon may have been overlooked in the other 80 per cent. The theoretical relationship of splanchnic vasodilatation to temperature has been considered. Additional evidence has been presented to support the concept of a splanchnoperipheral balance.

Shrunk Lobe with Bronchiectasis.—Jones and Courmand present as an entity, the shrunk pulmonary lobe with chronic bronchiectasis and prove by clinical observations two probable mechanisms in the causation of pulmonary shrinkage: bronchial stenosis and chronic inflammation of the lung. In many instances a combination of these two pathologic states exists as shown by one of their cases. They believe that, besides the stenosis of a bronchus from outside pressure due to congested lymph nodes, the loss of the normal bronchial function and the inflammation of the bronchial tree by infection from the lymph nodes are definite factors in the causation of bronchiectasis. The authors are fully aware of the fact that there are many other causes of bronchial stenosis with resultant pulmonary shrinkage but they do not discuss them, as the cases they present seem to them to be attributable to bronchial stenosis and chronic inflammation of the lung. They discuss the question of the congenital origin of this condition and present two cases of chronic bronchiectasis with shrunk lobes due to possible congenital causes.

Iron in Blood—Sachs and his associates determined the iron content of whole blood in a large series of normal male and female subjects. They experimented on 100 medical students (men), varying in age from 20 to 25 years, and fifty nurses (women), varying in age from 20 to 30 years. They found that the average iron content of whole blood of the 100 normal men was 50.01 ± 2.56 mg per hundred cubic centimeters. The average for the fifty normal women was 42.67 ± 2.13 mg per hundred cubic centimeters. The blood of women has a definitely lower iron content than that of men. Iron in whole blood is almost entirely linked with the hemoglobin molecule. Since the quantity of nonhemoglobinous iron present in the serum and the cellular elements is very small the error in calculating hemoglobin from whole blood iron is negligible. On the basis that hemoglobin contains 0.335 per cent of iron, the authors conclude that the average normal blood of men contains 14.93 ± 0.76 Gm of hemoglobin per hundred cubic centimeters while the average normal blood of women contains 12.74 ± 0.66 Gm per hundred cubic centimeters. By dividing the number of milligrams of iron per hundred cubic centimeters of blood by the first three figures of the red blood cell count, a quotient, which Murphy, Lynch and Howard designated as the iron index is obtained. The authors found the iron index for normal men to be 10.01 ± 0.65 Gm, and for normal women 9.6 ± 0.56 Gm of hemoglobin per hundred cubic centimeters. The iron index is preferable to the color index because of the greater accuracy with which the former may be determined. The iron color index, based on the ratio of the percentage of iron to the percentage of red blood cells, is also preferable to the older hemoglobin color index. The advantages to be derived from the clinical use of this index lie in its accuracy and in the retention of the convenient +1 or -1 designation of the older hemoglobin color index.

Acidophilus Milk in Constipation—Weinstein and his associates treated thirty-six patients suffering from simple chronic constipation with acidophilus milk (1 quart daily), the cultures of which were known to be of high viability. All were ambulant. Of the patients who underwent the treatment twenty-seven reacted favorably and seven responded negatively, and in their cases the treatment was regarded as having failed. Two gave results that were neither positive nor negative. Of those who responded positively, fourteen were so called implanters, that is, they maintained a high acidophilus content in the intestine for from twelve to sixteen weeks after the discontinuance of the last course of milk treatment. During this period, no return to the former condition of constipation was noted. Two other patients showed distinct improvement sixteen weeks after the cessation of the treatment but *Bacillus acidophilus* was not demonstrable in their feces. The results indicate that the most favorable response will be obtained by the continued use of the milk over reasonably long periods with interruptions (so called rest periods) of from four to twelve weeks or even longer. Whether the administered aciduric organism actually becomes implanted in the intestine of the patient who responds positively after many weeks of feeding and intermission, or whether the constant application of the acidophilus milk under favorable conditions of diet (with milk, lactose or dextrin) stimulates to activity similar or closely related strains native in the intestine must be left an open question. Either of these two eventualities should lend strong support to the acidophilus principle.

Idiopathic Hypochromic Anemia—Beebe and Wintrobe gave five patients suffering from idiopathic hypochromic anemia beef steak with normal gastric juice, according to the method used by Castle in causing a remission in pernicious anemia. In no instance was there an increase in the percentage of reticulocytes or a rise of the hemoglobin, the volume of packed red cells or the red blood count. Following the administration in each instance of suitable amounts of iron ammonium citrate, the percentage of the reticulocytes rose promptly and there soon followed a rapid increase of hemoglobin, an increase in the volume of packed red blood cells and improvement in the patients' symptoms and general appearance.

Endocrine Dyscrasias and Mental Disorders.—Hutton and his associates attempted to determine whether there was a relationship between endocrine dyscrasias and mental disorders and whether correction of the endocrine disturbance would be valuable in the treatment of mental disorders. The pituitary products used were a commercial soluble extract from the anterior lobe of the pituitary (antuitrin) and posterior lobe extracts. They were administered hypodermically three times

a week in such doses as the patient could tolerate. The dose of posterior lobe extracts was kept below that which produced unpleasant abdominal cramps. The anterior lobe extract was given in doses of from 0.5 to 1 cc., depending on the patient's tolerance. Ovarian medication consisted of the residue or of one of the standardized preparations, more often the residue, and one ampule was given subcutaneously three times a week. If a standardized preparation was used, it was given on alternate days beginning a week before the expected menstrual period. Thyroid has been given by mouth. Of 172 patients recognized as having some endocrine defect, 267 per cent are now paroled or discharged, whereas the discharged and paroled patients from all the state institutions during the year ended June 1931 were only 17.3 per cent. This does not mean that endocrine therapy will replace the accepted psychiatric routine but that endocrine therapy should become a routine adjuvant to the psychiatric procedure when indicated.

Hypersensitivity to Acetylsalicylic Acid—Shookhoff and Lieberman report three cases of hypersensitivity to acetylsalicylic acid expressed by a syndrome of angina pectoris, accompanied in two cases by urticaria. None of the characteristic signs of myocardial infarction of the heart were present. A study of one case showed definite allergic manifestations and definite electrocardiographic changes in the attack produced by the ingestion of acetylsalicylic acid. The electrocardiographic changes disappeared before the subsidence of the reaction. This syndrome was produced in the patient with every administration of acetylsalicylic acid and was to some degree controlled by the administration of epinephrine. There were evidences of preexisting cardiovascular disease in all three patients.

Rhus Toxicodendron Poisoning—Gowen used the almond oil extract of Rhus toxicodendron in the treatment and prevention of eight cases of Rhus toxicodendron poisoning. The patients were from 5 to 54 years of age. One injection in the spring will protect susceptible persons for approximately one year. Injection of the almond oil extract not only is satisfactory therapeutically but also offers protection for the rest of the season and leads to milder attacks the ensuing year. Two patients were immune for one year without treatment after several annual injections. In two patients who are exposed annually immunity has been present for two years in one and five years in the other. The first injection was the best in adults and older children and the gluteal muscle in the young children. The skin was sterilized with tincture of iodine or dilute creolin solution. The injection was made deep into the muscle and a large drop of cellulose was placed

round the site of injection before the needle was withdrawn. This prevented any egress of Rhus toxin and eliminated the possibility of any local dermatitis of the skin round this area. In no case was less than 1 cc. (one injection) of extract used. More than two injections were never needed. Noticeable improvement varied from one to three days after injection.

Urinary Proteose—Tuft and Brodsky demonstrated the presence of an ether extractable substance, described as "urinary proteose" by Oriol, in the sixty-one examinations of the urine of forty-two allergic patients in slightly larger amounts than in the nonallergic controls, and although larger amounts were eliminated than in the quiescent periods, positive skin reactions of a specific character could not be elicited nor was treatment in three cases of chronic asthma followed by any improvement. It is doubtful from these observations and a review of the literature whether the proteose of Oriol has a specific immunologic basis.

Pulmonary Tuberculosis—Kramer studied the curves of the blood sugar of 100 tuberculous patients divided in two series, series A including patients who at one time or other had glycosuria and series B being the control group. The fasting blood sugars were invariably of normal range. Diabetic patients were not included. The author offers suggestions for classifying the curves of the blood sugar: type I, the high or diabetic curve; type II, the normal curve; and type III, the low curve. There were seventeen patients showing a high or diabetic curve. Twelve of this number were found in series A. Eighty-three patients had nondiabetic curves, fifty nine were normal and twenty-four showed low curves. The 17 per cent diabetic curves were much below the figures mentioned by some authors. The influence of the state of the tuberculosis on the curve of the blood sugar is indefinite. Although an occasional case of increased tolerance for carbohydrates may be observed in the late stages of tuberculosis, the author was unable to point out any direct bearing on the curves in the patients studied. He believes that the low proportion of diabetic curves and the comparatively high percentage of low curves may be interpreted as an indication that tuberculous patients have a higher tolerance for sugar and may explain the rarity of diabetes developing in tuberculosis.

The Pressor Principle, the Blood and Hypertension—With a mercury manometer Elliot and Nuzum registered the carotid blood pressure of a full grown rabbit under anesthesia with sodium amital (0.08 Gm. per kilogram of body weight in the vein of the ear). The blood to be tested was drawn with a large needle from the intercostal vein and the syringe emptied into a glass containing enough sodium citrate to make a total concentration of 0.4 per cent. The blood was brought immediately to the laboratory and injected into the external jugular vein of the rabbit. The hypotensive time from the

drawal of the blood to its injection was about five minutes. The amount of blood injected was 3 cc per kilogram of body weight. The lethal dose of the blood from persons both with normal blood pressure and with hypertension was approximately the same (from 6 to 8 cc per kilogram). The patients from whom the blood was obtained were carefully studied as to renal function, degree of arterial disease and height and lability of the blood pressure. With the exception of one patient who had malignant hypertension and renal failure and one who had a coronary thrombosis resulting in a lasting fall of the blood pressure, they belonged to the essential hypertensive group with constantly elevated quite stable blood pressures. Blood from laboratory workers and medical students having normal blood pressures was used for the control determinations. In most instances the result was a transitory rise of pressure followed by a prolonged fall. The average initial rise of pressure of the animals receiving blood from patients having hypertension was slightly greater and generally more prolonged than that observed in the control series. Alcohol, water and ether-soluble fractions of such blood gave uniformly a transitory fall in blood pressure. The hypothesis of a pressor principle in the blood stream of persons having consistently elevated blood pressures should be subjected to further experimental study for confirmation or refutation.

Determination of Nonprotein Nitrogen.—Daly describes a modified Koch method for the determination of nonprotein nitrogen, in which to 5 cc of blood filtrate in a tube graduated at 35 and 50 cc, 1 cc of the sulphuric acid-dioxide digestion mixture 2 (prepared by adding 3 cc of a 30 per cent solution of hydrogen dioxide to 47 cc of the stock solution of sulphuric acid [stock solution of sulphuric acid is prepared by adding 225 cc of concentrated sulphuric acid to 245 cc of distilled water in a liter flask]) and two glass beads or a quartz pebble is added. This is heated with the full flame of the micro burner until the dense white fumes of sulphur trioxide appear, the mouth of the tube is closed with a small funnel and the flame is regulated until the digestion mixture barely boils. The material should be completely oxidized and the digestion mixture will be colorless. If there is a definite brown color due to unoxidized material the digestion mixture is too weak and more dioxide should be added. The gentle heating should be continued for about two minutes and then the tube should be removed from the flame. There are usually significant amounts of dioxide present at the end of the digestion but they do not interfere when the solution is nesslerized. When occasional determinations are made it is more convenient to use digestion mixture 1 (prepared by adding 6 cc of water to 94 cc of the stock solution of sulphuric acid) and adding the oxidizing agent separately. When the digested material is cold, 1 cc of a 1 per cent solution of gum ghatti is added and diluted to 35 cc. In another tube 1 cc of digestion mixture 1 without dioxide, 3 cc of the standard nitrogen solution and 1 cc of solution of gum ghatti is added and diluted to 35 cc. Nessler's solution with sodium citrate, 15 cc is measured into a small cylinder and with the 35 cc solutions of nitrogen it is poured simultaneously into a 400 cc beaker whirled and poured back into the graduated combustion tube. The solutions should be at room temperature when nesslerized. After the air bubbles have disappeared the nesslerized solutions should be crystal clear. The standard and unknown solutions are nesslerized as near together as possible and read at once in the colorimeter. Calculation of the results is made in the regular way.

Abdominal Symptoms in Heart Disease.—Ginsberg states that chronic abdominal symptoms are produced by valvular disease with decompensation and disease of the coronary artery with or without decompensation. Acute abdominal symptoms are produced by (1) disease of the coronary artery (angina pectoris and coronary thrombosis), (2) valvular disease (subacute bacterial endocarditis with or without emboli, mitral stenosis and congestive heart failure, right ventricle), (3) pericardial disease (acute pericarditis with or without effusion) and (4) arrhythmias (auricular fibrillation with or without emboli, auricular flutter paroxysmal tachycardia and bundle-branch block).

*Oral Bismuth in Treatment of Syphilis R O Brigham Toledo—p. 556

Oral Bismuth in Treatment of Syphilis.—Brigham treated a number of patients suffering from syphilis with glycerite of bismuth administered orally. There has been marked improvement both clinically and serologically. The dosage is often run up to 20 minims (13 cc) three times a day. In weak and poorly nourished patients this dosage shows slightly toxic results manifested first in a soreness of the gums similar to that due to mercury. When the dosage is reduced, these symptoms quickly disappear. Glycerite of bismuth has long been used as a tonic, and patients usually remark that they feel much better after taking the bismuth preparation. In no case in which it has been used has the preparation failed to produce good clinical results and only in a few cases did it fail to produce excellent serologic results. The medication of this form of bismuth was frequently continued for a period of three months with a brief rest and then another period of three months to clear up old cases. The oral administration of bismuth has proved a palatable way of giving the drug and is well tolerated by the patients and many of them prefer it to hypodermic medication. The advantage over the hypodermic medication is that the patient is getting a continuous daily supply of bismuth and not in large doses at frequent intervals.

Drug Treatment of Spasm of Ureter—Samaan carried out a series of experiments to determine the degree of action of definite dilutions of papaverine, visamin or atropine on the intestine and the virgin uterus of the rabbit, the ureter of the bull, the human ureter and the bladder of the dog. He found that atropine relaxes the intestine and the virgin uterus of the rabbit, the ureter of the bull and of man and the bladder of the dog if already put in a state of spasm through parasympathetic stimulation, whereas it fails to relax these organs if the cause of the spasm is directly muscular. For the bladder or for the uterus, visamin and papaverine are practically of equal values in relaxing these organs. Relaxation results if the spasm is mediated through the nerve, the muscle or both. Papaverine and visamin relax plain muscle tissue by direct action. In the same concentrations papaverine is a more efficient drug than visamin on the intestine, while the contrary is true for the ureter of the bull and of man. This makes visamin a drug superior to papaverine in the treatment of spasm of the ureter and of ureteral stone. Relaxation results if the spasm is mediated through the nerve, the muscle or both. The superiority of visamin over papaverine or atropine in relaxing the human ureter as established by pharmacologic experiments led to its clinical trial in cases of ureteral stone. Stones were passed through the natural passages after treatment with a warmed mixture containing 5 cc of tincture of ammi visnaga (1:10 solution of 90 per cent alcohol) and 30 cc of decoction of ammi visnaga (1:40) taken three or four times daily with an occasional intermission of the drug.

Urinary Acidifiers and Antiseptics in Pyelitis and Cystitis—Mitchell and Scott present a clinical study of seventy-five cases of pyelitis and cystitis in which urinary antiseptics and acidifiers were used. They observed that ammonium phosphate and benzoate are effective urinary acidifiers but a change of pH has no influence on the infection. Hexylresorcinol, pyridium and helmol have given no evidence of a urinary antiseptic value. Methenamine in well acidified urine cures at least one third of the nonsurgical cases of pyelitis and cystitis. Methenamine is liberated at the kidney pelvis at least and is as effective for pyelitis as it is for cystitis. Resistance to formaldehyde may be due to an individual characteristic of the organism. Focal infection (colonic absorption) seems to have a place in the etiology and treatment of persisting infections of the urinary tract. Urinary infection in simple pyelitis or pregnancy persists and disappears only post partum.

Osteitis Fibrosa and Parathyroid Tumors—Abel and his associates report a case of osteitis fibrosa, which was successfully treated by the removal of parathyroid tumors, in a woman aged 58. She had had several attacks of quinsy, acute appendicitis and Bacillus coli pyelitis two years before. Her health was good until the urgent operation for acute appendicitis was performed. After the operation she never felt that she could walk properly. Her strength did not seem to improve, and twelve months before she noticed that instead of becoming stronger she was actually much weaker. She had weakness of all her limbs, but more especially of the right arm. Pain was felt over the middle of the left leg and appeared to be in the bone itself. She always felt tired and faint. The pain in the leg increased, and a swelling appeared over the anterior aspect of the left tibia and increased in size up to 2 inches in vertical diameter. More indefinite aching pains were noticed in the other extremities. Roentgenography showed a cystic area in the left tibia at the junction of the upper and middle thirds and at the inner part of the upper end, involving both the shaft and the epiphysis. The knee joints showed calcification on the surfaces of the cartilages. Microscopic examination showed the changes typical of osteitis fibrosa. Further roentgenographic examination revealed parathyroid tumor. After a rest of ten days and a high calcium diet the patient was operated on under nitrous oxide-oxygen anesthesia. A Kocher low collar incision was made and the left side was explored first. A superior parathyroid, about three times the normal size, was found and removed. On the right side, four small rounded bodies were found behind the lower part of the thyroid bed. Two were removed for microscopic observation. They were found to be lymph nodes. The thyroid was replaced in its bed, the pretracheal muscles were sutured and the wound was closed, after drainage was provided for. Seventy-two hours after operation the serum calcium had fallen to 125 mg per hundred cubic centimeters. On the sixth day two attacks of paroxysmal tachycardia occurred. Digitalis was administered, with hypodermic injections of morphine. The pulse remained rapid for some days but gradually became normal. A fortnight after operation the serum calcium was still 125 mg. Convalescence from then on was quite uneventful. A high calcium diet was administered as soon as possible after operation with viosterol and ultraviolet radiation. Ten weeks after operation the pains of the bones had disappeared. The patient was steadily gaining weight and was able to walk a little.

Blood Sedimentation Rate and Vernes Flocculation Test in Tuberculosis—James confirms the work of previous authors in that both the determination of the rate of blood sedimentation and the Vernes flocculation test are of considerable value in the control of the treatment and prognosis in

cases of pulmonary tuberculosis. Provided all precautions were taken and with certain recognized exceptions, the figures for the two tests were comparable, particularly in infections that were comparatively early or but moderately advanced. In the advanced cases it was felt that the Vernes test represented the clinical condition less accurately than did the rate of blood sedimentation. Of the two methods of investigation it must be considered that the estimation of the rate of blood sedimentation is more applicable to everyday clinical work and that there is no information given by the Vernes test which cannot equally be supplied by the rate of blood sedimentation. The advantages of the latter method may be summarized as follows: 1 The Vernes test, because of elaborate laboratory methods and material, is a much more expensive test than the sedimentation test. 2 Any medical practitioner can do a sedimentation test at the bedside if necessary. 3 The rate of sedimentation actually gives considerably more information than the Vernes test. In the Vernes test one has only an end figure. 4 The 1 cc. technique for the sedimentation test is a simple matter for the patient and occasions practically no discomfort. For the Vernes test it is necessary to withdraw at least 10 cc. of blood. For the Vernes test also a fast of about fifteen hours is necessary before the test is made. 5 Blood for the Vernes test must be sent to a laboratory in which there are the requisite facilities. The sedimentation test may be performed anywhere.

Swift's or Pink Disease.—McDonald gives an account of recent work on the etiology and pathology of pink disease. He describes six cases that were apparently benefited by liver treatment. He used a preparation of pig liver. It can be made up as a soup or mixed with other food. Adults generally do not consider it palatable, children with pink disease will often take it freely undiluted. The dose for an adult patient with pernicious anemia is from 5 to 10 cc. three times daily. For the child with pink disease 5 cc. twice a day is sufficient.

Anemia-Causing Action of Hydrazine Derivatives.—Minami found no anemia-causing action in hydrazine sulphate. Chemicals that have the benzene nucleus such as phenylhydrazine, *p*-tolylhydrazine, α -methylhydrazine, *p*-nitrophenylhydrazine, *p*-methoxyphenylhydrazine and *p*-ethoxyphenylhydrazine hydrochloric acid have a fairly strong anemia-causing action. Chemicals having the naphthalene nucleus have also a fairly strong anemia-causing action but show generally slightly weaker action than chemicals having the benzene nucleus. Chemicals having the quinoline nucleus have a weaker anemia-causing action than those having the benzene nucleus. Among the chemicals having the benzene nucleus if phenylhydrazine hydrochloric acid is taken as the standard and one methyl radical is added to the benzene nucleus of phenylhydrazine hydrochloric acid the anemia-causing action of the chemical decreases. The action appears to decrease with the increases in the number of methyl radicals. The addition of the nitro radical to the benzene nucleus of phenylhydrazine hydrochloric acid increases the strength of the anemia-causing action. The phenylhydrazine hydrochloric acid having the methoxy radical slightly increases the anemia-causing action and that having the ethoxy radical shows nearly the same

degree of anemia-causing action as phenylhydrazine. In the case of the carboxyl radical to the benzene nucleus, the anemia-causing action disappears entirely. The β -naphthylhydrazine hydrochloric acid shows a stronger anemia-causing action than the α -naphthylhydrazine hydrochloric acid. Anaquinolin hydrazine hydrochloric acid shows a stronger anemia-causing action than orthoquinolinhydrazine hydrochloric acid.

Effect of Bismuth on Experimental Nanukayami.—Moriguchi tested the effect of bismuth on nanukayami (an endemic infectious disease resembling Weil's disease) by infecting guinea-pigs with *Spirochaeta akiyami* A, the results were satisfactory. After inoculating guinea-pigs with *Spirochaeta akiyami* A, he injected subcutaneously a 1 per cent solution of potassium and sodium bismuth tartrate every twenty-four hours, using 1 cc. per hundred grams of the body weight. The controls showed characteristic symptoms of nanukayami and had spirochetes in the liver. No animal injected immediately after inoculation developed symptoms of nanukayami. As no spirochetes were noted by dark field examination, the author made an emulsion of the liver to verify whether or not it had infective power for test animals and found that it had not. Seven animals were injected twenty-four hours after inoculation of which two were observed to live normally for more than a month. The others died but no lesion was discovered at necropsy to implicate nanukayami as the cause of death. Of three animals injected forty-eight hours after inoculation one lived more than a month and the other two showed no lesions of nanukayami at necropsy. The animals injected seventy-two hours after inoculation followed the same fate as the controls in one or two days. But the symptoms peculiar to nanukayami were much slighter and no spirochetes were discovered in the liver. The author shows that potassium and sodium bismuth tartrate has a positive effect when injected within forty-eight hours after inoculation (and even when injected seventy-two hours after inoculation) and concludes that potassium and sodium bismuth tartrate has a remarkable effect both as a preventive and as a curative.

Treatment of Meningococcus Sepsis with Acriflavine Hydrochloride.—During the last few years, Kashiwabara encountered five cases which presented high remittent fever, eruptions closely resembling erythema nodosum and arthralgia. He made clinical observations in each case and states that the present cases most closely corresponded in their clinical appearance with the "slowly developing meningococcus sepsis" described by Friedmann and Deicher. However, he could not demonstrate meningococci in the blood of each patient. He used injections of acriflavine hydrochloride and cured each patient.

Immediate Treatment of Fractures of Base of Skull

—Lenormant and his associates say that, in the first twenty-four hours, abstention from treatment is indicated on the one hand in hyperacute cases exhibiting signs of prostration, fever of 40 C (104 F) and abolition of the corneal reflex and, on the other hand, in so-called benign cases in which the symptoms recede quickly. Signs of intracranial hematoma are an indication for surgical treatment. If an extradural hemorrhage is discovered after the skull has been opened, the clots must be carefully removed and the source of the hemorrhage located if possible. If temporal trepanation discloses a dura mater that is violet and taut and the clinical signs indicate intracranial hematoma, the meninges should be incised. If neither an extradural nor a subdural hematoma is found, exploration of the opposite side of the head may disclose a counterblow lesion. In cases of deep intracranial hematoma, the results of this second examination are negative. In the cases of grave cerebral concussion the choice of treatment is governed by the succession of physiopathologic phenomena. It is of prime importance to measure the arterial and spinal fluid pressure as the symptoms of hypotension and hypertension are often similar. In primary hypotension, from 20 to 40 cc of distilled water should be injected intravenously and, if this fails, from 500 to 1,000 cc of physiologic solution of sodium chloride. In hypertension there is the choice between lumbar puncture with manometric control and hypertonic medication. In certain grave cases, interpretation of the signs is uncertain although indispensable to rational treatment. The cause of a syndrome of intracranial hypertension may remain obscure and the Queckenstedt-Stookey test and measurement of the tension of the central artery of the retina may be necessary to determine whether the hypertension is free or blocked. In the latter case ventricular exploration by puncture at the inferior occipital point may disclose one of three conditions. Both ventricles may be obliterated by cerebral edema or, rarely, bilateral hematomas. Bilateral temporal trepanation is the only logical therapy under those circumstances. If one of the ventricles is dilated while the other one is obliterated, trepanation of the foramen on the affected side is indicated. If the result is negative evacuation of the dilated ventricle by puncture is indicated. In some cases ventricular puncture may disclose dilatation of both ventricles. This may be due to obliteration of the passages connecting the intracerebral system with the subarachnoid spaces or to the insufficiency of these passages. Withdrawal of ventricular fluid may suffice if the drainage passages are free, if they are not, repeated evacuations will bring no improvement and drainage of the subarachnoid spaces at the posterior cisterna magna is required. The authors discuss the treatment to be given after the first thirty-six hours in cases that did not show early improvement. Continued hypotension demands the injection of water or physiologic solution of sodium chloride. Secondary hypertension is much more frequent. It imposes temporal trepanation in cases in which a reassuring clinical picture in the first twenty-four or forty-eight hours is succeeded by more complete coma, epileptiform crises or paralysis, indicating a localized lesion. Temporal trepanation is not satisfactory in exacerbation of the concussion syndrome with discovery of blood in the subarachnoid spaces indicating compression or irritation of the medulla and in cases in which cerebrospinal block exists. In the latter cases if the fluid obtained by suboccipital puncture is bloody and hypertensive the block is paramedullary or cervical; if it is not the block is located higher up. In cases of hypertrophic concussion trepanation with an osteoplastic flap (Arnold) at both lateral surfaces of the foramen or perhaps posterior trepanation may be employed. In all these cases suboccipital trepanation is indicated.

Vaccine and Serum Therapy in Prevention of Tetanus

—The Clavels state that in rare instances patients have succumbed to tetanus or presented manifestations of attenuated tetanus despite correctly executed surgical disinfection and prophylactic serotherapy. To prevent such occurrences they recommend that antitetanus serotherapy be supplemented by vaccination with tetanus anatoxin in cases in which the patient has one or more wounds that may remain infected with tetanus bacilli for a long time. To the passive immunity, rapidly induced by the serotherapy but of brief duration, vaccination adds an active immunity which is slowly produced but of very long duration. The combined therapy gives the patient a maximal guarantee against the danger of tetanus which is not only an immediate but a long term menace in certain cases. Vaccination with anatoxin is absolutely innocuous, it may be employed simultaneously with serotherapy and confers an immunity that lasts for several years. Vaccination with anatoxin is indicated in the case of a wound the evolution of which is long and may require successive interventions. Conservative interventions require antitetanic vaccination more than amputations, as they often take longer to heal and may retain a tetanus infection despite the vigilance of the surgeon. Vaccination is also indicated in case of multiple traumas, since in the presence of a grave trauma, as for instance rupture of the spleen, smaller wounds of the face or the extremities might receive insufficient attention. In the aforementioned cases the authors give an injection of from 10 to 20 cc of antitetanus serum immediately after the accident. Then with another syringe and at a different point a subcutaneous injection of 0.5 cc of anatoxin is given, ten days later they inject 1 cc of anatoxin and two months later 2 cc of anatoxin. In case of reintervention several months or years later, from 1 to 2 cc of anatoxin is again injected, and in this case a new antiserum injection can probably be dispensed with. In time of war all soldiers should receive antitetanus vaccination and in civilian practice it should be given to all laborers whose profession exposes them to frequent injuries susceptible to tetanic infection.

The Weinberg Reaction in Diagnosis of Echinococcosis—From a series of experiments, Outermino Nunez and Calvelo Lopez conclude that the Weinberg reaction, a complement fixation reaction for the diagnosis of echinococcosis which uses the fluid from hydatid cysts of sheep as antigen, is not specific for hydatid disease but is rather a group reaction. This conclusion is based on the following experimental results:

- 1 The antigen prepared by them from *Taenia saginata* (alcoholic extract) fixes complement in the presence of serums or patients with hydatid cysts with intensity as great as or greater than the fluid from the cysts of sheep.
- 2 The serums of patients harboring intestinal tremors, of animals infested with various forms of tremia or their embryos and of animals immunized by parenteral administration of proteins derived from these parasites give equally positive reactions with the extract of tremia and with the hydatid antigen.
- 3 Positive results were also obtained with both antigens in certain non-parasitic diseases.
- 4 In general, inactivation is followed by the destruction of antibodies in varying degrees; the reactions being weaker with the heated serums than with those used without inactivation.

Aperticities Causé Observées from 1928 to 1932 at Hôpital Frauenfeld W. J. Ler—p 1121

Toxic Injuries of Chemical Origin Particularly Nerve Gas Caused by Ink Pencils J. de Puy—p 1124

Icterus Neonatal et Gravissimae Fœtal Constriction of Infection T. H. Fuchs—p 1129

Determination of Blood Coagulation V. Hoffmann—p 1134

Injury Case G. Franch—p 1135

Injuries Caused by Ink Pencils—Experimental and clinical observations conducted de Puy that the noxious agent is

ink pencil injuries is the dyestuff component, which is always an aniline dye. The greater the alkalinescence of the dyes, the greater also their harmfulness. A prolonged influence of the aniline dyes results in headaches, loss of appetite, general debility and increased temperature. Early appropriate treatment prevents the general reactions. Studies of the local symptoms disclosed that the portions of the ink pencil that have entered the tissues are dissolved by the tissue fluids. The dissolved dye becomes diffused and exerts a necrotizing effect. The injuries produced by ink pencils are particularly severe when they involve a mucous membrane, especially the conjunctiva, where they produce extensive ulcerations. The author gives a summary report of thirty-three injuries produced by ink pencils. This report indicates that surgical therapy gives better results than conservative measures. The author recommends the radical excision of all tissues that have become discolored by the dye. Subsequent irrigation with tannin and wet dressings accelerate the healing process, and some authors have seen favorable effects from after-treatment with ultraviolet rays.

Icterus Neonatorum Gravis—In a review of the literature on icterus neonatorum gravis Fuchs shows that it largely concerns itself with the familial form. It is his aim, however, to differentiate distinct groups and to call particular attention to an infectious form. In four children who developed a severe icterus during the first three days of life, he discovered a septic infectious process either during life or in the course of the necropsy. In three of them the infection originated in the umbilicus. All four children had convulsions or spasm of the muscles of the extremities as signs of a cerebral involvement. The children were apathetic and did not nurse normally. Their stools showed biliary discoloration. The blood either showed no erythroblastosis or the values were still within normal limits. In three cases the urine contained dissolved bilirubin. All but one of the children died within the first two weeks of life. Since the children were the first ones in their families to develop icterus neonatorum, the cases could not be definitely diagnosed as the familial form. The first two of the children were siblings, and consequently the familial form could be thought of, since the most characteristic symptom, erythroblastosis, was absent, however the diagnosis was not made. The author considers it probable that this family may have a predisposition to severe icterus or a susceptibility to infections. In the second and third cases the same bacterial flora was found in the vagina of the mother and in the umbilical pus of the infants. The fourth infant showed nearly all the signs of the familial form of icterus neonatorum gravis. The presence of the septic infection was the only factor that militated for a differential diagnosis of infectious icterus neonatorum. In his discussion of the familial form, the author shows the significance of the differentiation between the two forms. In addition to these two types he recognizes yet a third type of icterus neonatorum gravis. To this group he assigns all cases that are neither familial nor infectious. Whether in this third form there exists a deficient capacity for independent extra-uterine existence cannot be definitely determined as yet.

Pulmonary and Thoracic Actinomycosis—Foltz and Canavero made a study of a patient suffering from bilateral pulmonary actinomycosis with involvement of the pleura and the thoracic wall. The authors do not recognize the existence of two separate forms of pulmonary actinomycosis, the superficial and the ulcerative. They demonstrate that it has no anatomic basis but only a pathogenic one. They distinguish between actinomycosis involving pulmonary tissue alone (superficial actinomycosis of other authors) and that of a pulmonary thoracic

variety. In the latter they distinguish between pulmonary actinomycosis spreading to the thorax and primary actinomycosis of the thorax spreading to the lung. Regarding the pulmonary origin of the pulmonary thoracic form, the authors attribute the notable presence of pseudo-adenomatous formations to proliferation of the bronchial epithelium.

Approach to Ribs in Apicectomy—Broglio describes the following operative technique. The patient assumes the position ordinarily used in intervention on the thyroid with the head extended and turned slightly away from the side operated on. The intercostal nerves are blocked with a 0.5 per cent solution of tutocain, and a 0.25 per cent solution is used for infiltration anesthesia. A rectangular incision is made, starting 5 cm above the sternoclavicular articulation, passing over the joint and ending at the upper margin of the second costal cartilage, the horizontal limb of the incision follows the upper margin of the second rib and stops at the outer third of the clavicle. About 40 cc of the anesthetic is used for further infiltration. The aponeurosis of the supraclavicular fossa is divided, the sternoclavicular articulation is opened and the muscular bundles of the pectoralis major are divided 1 cm from their insertion on the sternum together with the aponeurosis. Blunt dissection separates these bundles from the rest of the pectoralis muscle and stops at the vascular pedicle. The posterior aspect of the sternoclavicular articulation is separated from the surrounding tissues and the clavicle is dislodged and freed. The upper aspect of the first and second ribs is anesthetized and the periosteum is detached, care being taken to avoid division of the pleura. The ribs are resected at their union with the costal cartilage and at a point beyond the posterior costal angle. The operation is completed by replacing the luxated extremity of the clavicle and reconstructing the planes of the thoracic wall. The clavicle is held in place by fibroperiosteal sutures made with interrupted catgut. A rubber tube is placed at the external angle of the wound to assure drainage and is removed in clean cases after forty-eight hours. The great advantage of this method is the possibility of resecting the ribs under visual control.

*Intravenous Alcohol Injections in Treatment of Pneumonia E. Jaso and M. Quero Malo —p. 542

Surgical Therapy in Tumors of Renal Pelvis S. Pascual —p. 550

Alcohol Injections in Pneumonia in Children—Jaso and Quero Malo advise the use of intravenous injections of alcohol in the treatment of pneumonia in children. The injections consist of 5 cc of a 33 per cent solution of alcohol in physiologic solution of sodium chloride preferably given as soon as the diagnosis is made and repeated daily until the crisis of the disease is reached. It is advisable to increase the dose in children more than 6 years of age. The injections have an antithermic effect and also a regulating effect on the pulse. The temperature shows a tendency to become normal following the first injection. The treatment has no influence on the rate of respiration. It has, however, a favorable influence on the disease by maintaining the resistance of the patients so that they go through the disease in a good general condition, do not lose their appetite and do not have diarrhea as a complication. It has also a favorable influence on the evolution of the pulmonary condition, which is manifest by the early appearance of crepitant rales on the third or fourth day of the disease and by the rapid resolution of the pulmonary lesions and disappearance of the pulmonary infiltration, as proved by roentgen examination of the lungs. The duration of the pneumonia is greatly decreased, especially when the injections are given from the first day of the disease. In these cases the disease follows a benign evolution and its duration is of not more than five days. The percentage of mortality from pneumonia in children is greatly reduced by the administration of this treatment. The author has obtained satisfactory results in fifteen cases, of which twelve were lobar pneumonia and three bronchio pneumonia.

Pneumoroentgenography of Knee Joint—Schum maintains that internal injuries of the knee joint cannot be detected by means of the ordinary clinical examination. In order to avoid unnecessary arthrotomies and yet be able to make a definite diagnosis, he employs pneumoroentgenography. The needle, which he employs for the introduction of air into the joint, resembles the pneumothorax needle, that is, it is closed at the end and has the opening at the side. This arrangement prevents undesirable air inflation of the tissues. The lumen of the needle should not be too narrow, so that articular exudate which may be present can be discharged through it. The discharge of such an exudate indicates that the needle is located properly in the articular cavity, and the complete elimination of this fluid is an absolute requirement for the success of the roentgenography, since otherwise the air cannot penetrate into the different spaces. The inflation of the joint is done slowly. Since complete expansion of the capsule is absolutely necessary, 60 cc of air is the least that should be introduced, but in some cases as high as 200 cc can be injected. However, excessive amounts are not advisable, because emphysema of the soft parts will cause a distortion of the roentgen picture. All roentgenograms are made stereoscopically. One exposure is made in the sagittal plane and the other vertically to it. Occasionally an oblique exposure may be helpful. Since the demonstration of changes in the ligaments, cartilages and menisci is the primary object of pneumoroentgenography, the author employs soft ray tubes and makes the exposures as short as possible. He used this method in 233 examinations on 190 patients and never observed complications. He discusses the pathologic conditions that he discovered in the course of these examinations such as joint mice, injuries of the crucial ligaments and of the menisci, ruptures of the cartilages and deformities of the capsule. He calls attention to the fact that air inflation of the knee joint can be used also for therapeutic purposes. He states that patients with chronic dropsy frequently asked for a new air filling because it gave them great relief. He found it helpful also in postoperative exudates and in exudates caused by injuries. In case of post-traumatic accumulation of blood or fluid a single injection of air may be sufficient and even inflammatory exudates, which rarely yield to puncture alone, have yielded to air filling.

Lead in Blood and Urine of Patients with Lead Poisoning—Bass points out that the diagnosis of lead poisoning may be difficult in cases in which the lead line stippled erythrocytes and porphyrinuria are absent. Until recently the methods for the quantitative determination of the lead content of blood and urine were inadequate. However, since P. Schmidt and his co-workers devised an electrolytic colorimetric method the analysis of blood and urine has proved helpful in the diagnosis in the evaluation of benefit claims and in the estimation of the efficacy of therapeutic procedure. The method developed by Schmidt extracts the lead by precipitating the incinerated material with hydrogen sulphide and by electrolysis the lead is deposited at the anode in the form of lead superoxide. By immersing the latter in a solution of tetramethylammonium diphenylmethane in glacial acetic acid a blue dye tuff is obtained and is then colorimetrically compared with a comparative solution. The margin of error never exceeds 0.02 mg. Thus the procedure has a sensitivity that permits the detection of the smallest quantities of lead. The author notes that entirely healthy persons who have never come in contact with lead have minute amounts of lead in their blood and urine, the average being 0.02 mg. in 100 cc of blood or in 1000 cc of urine respectively. As the threshold values above which signs

of lead poisoning tend to appear, Schmidt and his co-workers have given a lead content of 0.06 mg. in 100 cc of blood and of 0.1 mg. in 1,000 cc of urine. From observations on forty patients with lead poisoning, the author concludes that the quantitative determination of the lead content of the blood and urine is of great value in the diagnosis and estimation of lead poisoning but careful clinical observation cannot be dispensed with.

Deutsches Archiv für klinische Medizin, Berlin

- Diagnosis of Syphilis of Joints Z Gerskovic and M Brenner—p. 637
*Osteoporotic Obesity (Pituitary Basophilism) E Rutishauser—p. 640
Criticism of Alkaline and Acid Methods for Determination of Iodine Content of Blood H Lucker—p. 681
*Diagnosis of Disturbances in Pancreatic Ferments Diastase Content of Blood in Diseases of Biliary Passages and of Duodenum J Brinck and Rodriguez Oliveros—p. 691

Osteoporotic Obesity (Pituitary Basophilism)—Rutishauser emphasizes that osteoporotic obesity must be differentiated from adiposogenital dystrophy (Frohlich's syndrome), with which it has two symptoms in common, namely, obesity and hypoplasia of the genital organs. The differentiation can be based on the presence of osteoporosis and of high blood pressure and on the absence of visual impairment and of increased cerebral pressure the latter two symptoms being nearly always present in adiposogenital dystrophy. The hypophyseal changes which the author observed in osteoporotic obesity are the following: a small basophil adenoma of the anterior lobe, numerous nodule-like, basophil hypertrophies and severe malformations in the region of the posterior lobe, the latter being interpreted as an agenesis and increase in the basophil cells involving the entire anterior lobe. In one case an alcoholic cirrhosis of the liver existed. The increase in the basophil cells does not necessarily have to assume the form of an adenoma. In two cases in which a basophil adenoma of the hypophysis could not be found, the increase in basophil cells could be traced to the primary disease, in the second case to agenesis of the posterior lobe of the hypophysis, and in a third case to alcoholic cirrhosis of the liver. The author found that the suprarenals were either well developed or hypertrophic. The hypertrophy involved both the cortex and the medulla. The ovaries were atrophied. In one case it never came to the development of the graafian follicles. The thyroids were atrophic, were poorly developed or showed degeneration of the colloid or goiter. The parathyroids were lipomatous but not always equally severe in all four parathyroids. The changes in the skeleton were of an osteoporotic nature and in two cases the osteoporosis caused spontaneous fractures of the ribs.

Hypertension and Acidity of Tissues—Scharpff calls attention to studies which revealed that an abnormal retention of alkali is demonstrable in disorders with a vasoneurotic component (gastric ulcer, asthma, hypertension). Investigators who studied this problem in patients suffering from hypertension found that the retention of alkali is greater in younger persons than in older ones. To verify this observation the author decided to study alkali retention in older patients having hypertension. The average age of the forty patients whom he subjected to a sodium bicarbonate tolerance test was 58 years. Following elimination of all potassium, urine the patients received a bicarbonate solution and evacuated the bladder once more,

or a specimen was withdrawn with the catheter (test urine 1). Then they were given an intravenous injection of 20 cc of a 10 per cent solution of sodium bicarbonate, and two hours later the bladder was emptied once more (test urine 2). The degree of acidity of the two specimens was determined by means of the colorimetric method of Wulff. The results were not uniform. The differences in the pH values of the two specimens fluctuated between 0.3 and 2.0, and in one case the pH value was not changed at all. If the difference in the two specimens is slight, the alkali has been returned in the tissues of the patient if it is great, the elimination is good. The author observed that the treatment effected a considerable reduction in the blood pressure of patients who eliminated the alkali well, whereas the therapy was ineffective in those who retained large portions of the alkali. Thus the test is an aid in forecasting the probable development of hypertension.

Fever Therapy of Trigeminal Neuralgia.—In the treatment of trigeminal neuralgia, Bockheler employed a preparation which contains proteins from nonpathogenic bacilli primarily of the colon group. The first injection was generally made with 50 units, the second with 100, the third with 200 and so on until 500 units is reached. The total number of injections is usually from five to six, but in some cases from three to four may be sufficient, and in refractory cases from seven to eight injections may be given. The fever begins usually from one to two hours after the injection. During the following two or three hours it increases to from 39 to 40 C (102.2 to 104 F) and after another six or eight hours it begins to decline again. In the cases of trigeminal neuralgia, but also in other forms of neuritis, it was found that the greater the pain reaction of the involved nerve during the fever the better was the therapeutic result. Complications or injurious effects were never observed. The author gives the case reports of a number of patients who were subjected to this form of fever therapy. He does not wish to create the impression that fever therapy should replace surgical therapy entirely, but he thinks that, if his results with fever therapy could be duplicated by others, it would be advisable to try fever treatment first, and to employ surgical treatment only as a last resort.

Modification of Blood Pressure by Moor Baths.—In studies on the influence of moor baths on the blood pressure, Guthmann and Hess found that under the influence of the baths the daily fluctuations in blood pressure are comparatively mild. The less hot moor baths effect a greater reduction in the systolic pressure than do the hot baths. In contradistinction

to other investigators, the authors found that after hot baths there was no increase in the systolic pressure over the initial value, either in the average values or in the greatest number of individual cases. To be sure, the number of patients who show a short increase at the beginning and end of the bath increases with the temperature of the bath, but they always remain in the minority. The diastolic pressure decreases immediately after the onset of the bath. In the hotter baths this decrease is somewhat slower. The amplitude is temporarily increased during the bath, and this increase is not merely the result of the further decrease of the diastolic pressure but particularly of the comparatively lesser decrease in the systolic pressure. Hotter baths effect a greater increase in the amplitude in baths that are less hot the maximal increase in the amplitude takes place during the first part of the bath, while in the hotter baths the maximal amplitude is reached during the second half. The effect of water baths of the same temperature and of the same duration as moor baths is generally less prolonged. The quantitative changes likewise are often lesser. Under certain conditions, half moor baths of higher temperatures produce the same reactions as full moor baths of lower temperatures. By varying the mode of application (full and half baths) and the temperature and the duration of the baths, the reaction can be adjusted to the individual case. A complete series of moor baths does not change the blood pressure within certain limits. The primary blood pressure must be taken into consideration when the type of moor baths is decided. In case of hypotension, the patient has to be watched during the bath, because there is danger of collapse. This applies particularly to the hot baths with their greater action on blood pressure and pulse acceleration.

Carbon Dioxide in Treatment of Bronchial Asthma.—Farago shows that, in addition to the medicinal and dietary treatments, carbon dioxide inhalation has a certain place in the symptomatic treatment of bronchial asthma. He found that some asthmatic attacks and dyspneas can be favorably influenced by the inhalation of an 8 per cent mixture of carbon dioxide and oxygen. The inhalation of this mixture effects a decrease in the alkali reserve and an increase in the lactic acid content of the blood. The pH of the urine remains the same, while the ammonia elimination decreases.

Uric Acid and Hyperuricemia of Renal Origin.—Voigt recommends Folin's micromethod for the determination of uric acid. He stresses the advantages of the method, particularly its reliability. In order to illustrate renal insufficiency caused by "endogenic overburdening" with nitrogenous waste matter, especially uric acid, he describes a case in which pneumonia was complicated by nephritis. The renal insufficiency became manifest in the retention of large amounts of nitrogenous waste matters in the blood. The curve indicating the uric acid content of the blood was determined by means of pyrogenic uric acid tolerance tests in normal persons as well as in the patients having renal insufficiency. In normal persons presenting mild fever the curve rises only slightly, and after cessation of the fever the curve immediately returns to the normal level. In patients suffering from renal disturbances, however, the curve indicating the uric acid content rises comparatively high and the decline is extremely retarded. The uric acid content during rest and while the person is fasting shows a surprising individual constancy in normal persons but in persons having renal insufficiency there are great fluctuations, corresponding to the impaired eliminatory function of the kidney. The difference between the uric acid content of the blood and of the cantharides blister in patients having renal insufficiency makes possible the interpretation of a hyperuricemia and helps in determining its renal origin. In the case in which pneumonia concurred with nephritis, the disappearance of the renal insufficiency was accompanied by a steplike decrease in the difference between the uric acid content of the blood and of the cantharides blister. In latent renal insufficiency an artificial fever of short duration increases the difference between the uric acid content of the blood and of the cantharides blister to an extent that in persons without renal disturbances can be obtained only if the fever is high and prolonged.

JOURNALS ABSTRACTED IN THE CURRENT MEDICAL LITERATURE DEPARTMENT, JULY-DECEMBER, 1933

Abstracts of important articles in the following journals have been made in the Current Literature Department of THE JOURNAL during the past six months. Any of the journals, except those starred, will be lent by THE JOURNAL to subscribers in continental United States and Canada and to Fellows of the American Medical Association for a period not exceeding three days. Two journals may be borrowed at a time. No journals are available prior to 1925. Requests for periodicals should be addressed to the Library of the American Medical Association and should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Thus most of these journals are accessible to the general practitioner.

SUBJECT INDEX

This is an index to all the reading matter in THE JOURNAL. In the Current Medical Literature Department only the articles which have been abstracted are indexed.

The letters used to explain in which department the matter indexed appears are as follows: "BI," Bureau of Investigation, "E," Editorial, "C," Correspondence, "ME," Medical Economics, "ab," abstract, the star (*) indicates an original article in THE JOURNAL.

This is a subject index and one should, therefore, look for the subject word, with the following exceptions: "Book Notices," "Deaths," "Medicolegal Abstracts" and "Societies" are indexed under these titles at the end of the letters "B," "D," "M," and "S." State board examinations are entered under the general heading State Board Reports, and not under the names of the individual states. Matter pertaining to the Association is indexed under "American Medical Association." The name of the author, in brackets, follows the subject entry.

For author index see page 2211
